LABURNUM FLOWERING IN SEPTEMBER.—T. H., Tewkesbury: The flowering of the laburnum at so late a date is due to the prolonged dry and bright weather, coupled with some suitable local condition. The buds that should have remained dormant through the winter have extended, expanded, and produced flowers; it will be interesting to know how the tree will act in the coming year, and we shall be glad if you would make a note of its subsequent behaviour for us. A fortnight ago we saw a bush tree of Warner's King apple, about 9ft. high, and as much through, carrying scores of clusters of blossom. The tree was lifted last autumn for the purpose of checking excessive growth, and also because it was extending over a pathway; this season it carries a few fruits, has made little growth, and, as indicated, many of the buds have already produced flowers. Doubtless somewhat similar occurrences are numerous this season.

DISEASED CUCUMBERS. — R. M. P., Leicester: Eelworms are the cause of the trouble, and at this date it is useless to attempt a cure. Take out the plants and burn them, and thoroughly sterilise the soil with gas lime or great heat. Clean the pit thoroughly, not missing any part of it. If the pit needs painting let this work follow the cleaning, and then, with a coat of hot limewash on all the brickwork, the structure should be fit for occupation again. Next spring obtain soil from a new source, or else sterilise the compost before use.

NEW GARDEN WITH CHALKY SOIL.—M. M., Bucks: A garden at an elevation of 550ft. above sea level, on the chalk, facing north, and with a distinct slope towards the north, is in no sense an ideal one. One important bit of information you have omitted is the depth of soil over the chalk; so very much depends upon this, for unless you can trench the ground all over, or at least double dig it, the prospects of successful gardening are small. Pig and fowl manure are useful, but must be used sparingly, but leaf-mould, which you say can be easily obtained, should be added as freely as opportunity permits, while farmyard manure should also be used if obtainable. Arrangements must be made for the rapid removal of surface water at the lower levels. If the ground is terraced across the middle this would save labour eventually and serve to prevent the rainfall from passing too quickly from the upper portion; a wall or stout fence at this point would also afford opportunities for the culture of choice fruit trees on the southern exposure and hardier subjects on the northern side. If you can obtain a fair depth of soil practically all kinds of fruit trees could be cultivated, but stone fruits, such as cherries, plums, and damsons, would find the chalky soil to their liking. Bush trees would be preferable to standards on such a soil, and at such an elevation. If you take a quiet walk round the neighbourhood, and make notes of the crops that do best in the surrounding gardens, you will have an excellent guide for planting, and subsequent experience will soon enable you to add to the list of subjects. You have two great advantages to set against the several disadvantages, and these are a plentiful supply of fowl manure and leaf-mould. After the initial working, use leaf-soil freely for mulching any and every kind of crop, and, if the fowl manure is mixed with about twice its bulk of dry soil, and stacked in a dry open shed, it will provide excellent material for top-dressing in spring and summer for the purpose of accelerating growth and increasing the size of fruits.

IVY ON YOUNG TREE.—S. J. W., Minehead: It would be a great mistake to allow the ivy to strangle the tree. It will not be sufficient to sever the ivy at the tree base, and fork out the roots; every branch must be pulled from the tree trunk, or the aerial roots may keep them alive.

RED-PLUMED GRASS ON THE BROADS.—C. L. B., Derby: The strong-growing grass that is so common throughout The Broads of Norfolk and Suffolk, and which is particularly elegant at this season of the year, with its graceful red-purple plumes, is Phragmites communis. It grows in or close to water, and is widely distributed from Shetland to the Channel Islands, and found in all the Continents. It has many uses; in water gardening it occupies no mean position, provided there is room for it; as shelter for water fowl it is especially good; and the reeds are extensively utilised for thatching. On estates where the phragmites is plentiful the dried reeds provide a handy means of protection against frost and biting winds, as they can easily be made up into hurdles or into mats.

CHERRIES NOT CROPPING.—C., Kettering: Cherries are not a success everywhere; they like a goodly proportion of lime in the soil, ample drainage, and protection from cold winds when flowering. Bees do play a considerable part in the distribution of pollen, so that they are both useful and profitable in the garden and orchard.

NAMES OF PLANTS.

W. E. S., Chester.—Odontoglossum Lindleyanum.

T., Wells.—Your specimen was named in our issue of September 16.

C. O., Fairford.—Veronica anomala; see next issue for name of other specimen.

I. S., Croydon.—1, Calceolaria thyrsiflora; 2, Rudbeckia laciniata fl.-pl.; 3, Hibiscus syriacus.

C. G. B., Oswestry.—1, Sedum Ewersi; 2, Verbena venosa; 3, Colchicum autumnale; 4, Alyssum incanum.

P. P., Saxmundham.—1, Phragmites communis; 2, Ceratostigma plumbaginoides; 3, Solidago californica.

G. H. G., Devizes.—Hibiscus syriacus; there are a number of garden varieties of this useful autumn-flowering shrub, and they are all flowering well this warm season.

NAMES OF FRUITS.

D. S., Ipswich.—Lady Sudeley.

W. W. M., Aberystwith.—1, New Hawthornden; 2, Colonel Vaughan.

T. B., Medmenham.—1, Worcester Pearmain; 2, Warner's King; 3, King of the Pippins.

F. F. J., Leatherhead.—1. Golden Noble; 2, Peasgood's Nonsuch; 3, Catillac; 4, Blue Imperatrice.

W. K. E., West Bromwich.—1, Ribston Pippin; 2, not recognised; 3, Dumelow's Seedling; 4, Cox's Pomona; 5, Golden Noble.

R. M., Gosport.—1, Bismarck; 2, Worcester Pearmain; 3, not a good specimen, probably Bismarck; 4, Beurre Diel; 5, Louise Bonne of Jersey.

GARDENING ENGAGEMENTS.

Mr. J. J. Nock, a member of the gardening staff of the Royal Botanic Gardens, has been appointed by the Secretary of State for the Colonies, on the recommendation of Kew, Curator of the Hakgala Gardens, Ceylon.

Mr. William F. Rowles, for some years general foreman at Ickworth Gardens and previously of Tranby Croft Gardens, has been appointed head gardener to the Right Hon. Lord Ninian Crichton-Stuart, Falkland Palace Gardens, Falkland, Fifeshire. He enters upon his duties September 25.

INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.

To the Editor of The Gardeners' Magazine.

Sir,—The good people who are responsible for the management of the International Horticultural Exhibition of 1912 seem to have looked upon themselves as of so much importance that they could do just what they please—but I venture to think they are mistaken. We ordinary mortals who have to earn our bread and butter are not disposed to "table our dust" to the tune of two pounds for the privilege of entering the sacred precincts on the opening day, or for thirty shillings if we can proudly write F.R.H.S. after our humble names. I have talked to many an enthusiastic garden-lover—I am not thinking of our good friends in the trade—and they, one and all, are agreed that the promoters of the exhibition, if they persist in their course, are "riding for a fall." I would like my man to see the show, and would gladly give him a day off and pay his railway fare, but it is simply ridiculous to think of sending him up to town on the fourth or fifth day when every competitive exhibit would be as dead as mutton! For two guineas the promoters of the exhibition should issue a season ticket for the duration of the show. As an F.R.H.S. I am to lose my Temple Show, and I must pay £4 4s. if I wish to visit the exhibition on each day. I think there is a sixpence "thrown in," but that doesn't warm me in the least!—Yours etc.,

F. R. H. S.

CATALOGUES RECEIVED.

WILLIAM PAUL AND SON, WALTHAM CROSS, LIM.—This new catalogue of roses is as interesting and instructive as its many handsome predecessors. The varieties of roses listed and described are grouped in their several sections. The accompanying order sheet has all the varieties arranged in alphabetical index form, so that it is easy to find any special sort. Sylvia, Florence, and Haswell Veitch are represented in colours, and there are numerous black and white illustrations.

H. N. ELLISON, WEST BROMWICH.—Mr. Ellison issues a bulb catalogue that will especially appeal to those who do not want to wade through a large and complete list of varieties; he has seeds, ferns, and cacti, and for these two latter he has gained no fewer than five gold, seven silver-gilt, and ten silver medals during this season.

J. R. PEARSON AND SONS, LOWDHAM, NOTTS.—This firm has a long and excellent reputation for fruit trees, and their catalogue is a very useful one, because of the selection of varieties given, and the descriptive notes attached to each. Roses occupy the latter half of the catalogue.

J. A. COOPER, LISSADELL, SLIGO.—A pocket list devoted entirely to daffodils, this catalogue from the Lissadell Bulb Farm appeals alike to the specialist and the general cultivator; the choicest of varieties are included, many of them quite new.

THOS. S. WARE, LIM., FELTHAM.—A remarkable point about this autumn catalogue is its completeness. One section is devoted to bulbs, it includes the rare subjects, and is well illustrated; then follows sections on hardy perennials for autumn planting, carnations and picotees, roses, climbing plants, and fruit trees.

Our Work has stood the test of time.

MY SWEET PEA LIST

will be the most time-saving, interesting, profitable, and pleasure-giving list in the world. Post-card commands it.

I am being honoured with **novelties** from Aitken's, Chapman, Cole, Burpee, Deal, Dobbies, Hemus, Lumley, Stark, Trevethick, Ward, and many others.

My stock of last year's novelties are, with few exceptions, English grown and rogued by **genuine Sweet Pea lovers.**

My Special Spencer Mixture contains Earl Spencer, Nancy Perkin, Syeira Lee, Thomas Stevenson, Dainty, and Helen Pierce Spencers, etc. This I **guarantee. 1s.** per oz., **1s. 10d.** per 2oz., **3s. 6d.** per 4oz., post free.

My Helen Pierce Spencer Seedlings will be a source of profit and pleasure to the grower. The stock has been rogued down to Spencers at great expense. A selection from this mixture properly fixed will make a small fortune for the owner. **1s. 6d.** per oz., **2s. 6d.** per 2oz., post free.

My Special Seedling Spencer Hybrid Mixture is from two of our keenest British hybridists, who have more stock than they can possibly handle as it ought to be. **Such seed never offered before. 1s. 6d.** per oz., 2oz. for **2s. 5d.,** post free, worth 10s. per oz., as it is absolutely the result of their life's work. Virtually selling proverbial £1 for one penny.

Sole distributing agent for Mr. F. Herbert Chapman's Iolanthe, the most opaque white Sweet Pea in existence. 8 seeds, **6d.;** 20 seeds, **1s.**

I hope to have my list ready early in October.

G. H. MACKERETH,
The Sweet Pea Clearing House, ULVERSTON.

W. SEABROOK & SONS

(Delivered Entirely Free in London)
OF

CHOICE HARDY BULBS.

COLLECTION "F" FOR SPRING GARDENING

Contains **1,140** Bulbs.

48 Hyacinths, distinct colours.
50 Tulips, single early.
50 Tulips, double.
50 Tulips, single, late.
50 Narcissus, best mixed.
30 Narcissus incomparable
24 Narcissus poeticus.
24 Anemones, double.
50 Anemones, single.
50 Gladiolus nanus.
300 Crocus, in 4 distinct colours.
100 French Ranunculus.
50 Snowdrops, single.
100 Spanish Iris.
36 Scilla sibirica (2 colours)
4 Lilium umbellatum.
50 Eranthis hyemalis (Winter Aconite).
50 Ixias, best mixed.
24 Triteleia uniflora.

HALF OF THE ABOVE FOR **11s.**

Our Bulbs are Perfect Bulbs direct from Holland—THE Great BULB LAND.

The above Package may be had from our Agents,

MERTENS & Co.,
3, Cross Lane, London, E.C.,
On Receipt of Cheque or Post Office Order.

Our **DESCRIPTIVE CATALOGUE** of SPLENDID BULBS (100 pages in English), containing FULL CULTURAL DIRECTIONS, will be sent post free on application to our Agents, as above, or ourselves direct at

OVERVEEN, HAARLEM, HOLLAND.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

The Storage of Hardy Fruits.

Fortunately for the owners of gardens and those responsible for their management, the crops of apples and pears, if not excessive, are sufficient to necessitate the fullest consideration being given to the question of fruit storage. The preservation of hard fruits, such as apples and pears, in the best possible condition over a long period, has so important a bearing upon the fruit supplies that it should be constantly kept in mind by cultivators until the best possible method has been devised for keeping the several kinds in really good condition throughout their respective seasons. It has been said on more than one occasion by those who take an active interest in this aspect of the fruit supply, that it is of little avail to make strenuous endeavour to produce abundant supplies of high quality if a considerable proportion is wasted through defective storage; but this truism is one that will bear repetition when the preservation of fruit in a fresh state is under discussion. Within recent years there has been a considerable improvement in methods of storage, but these have not kept pace with the improvements in cultural details, and therefore more has yet to be done before they can be regarded as satisfactory. This aspect of fruit production is still suffering from the mistaken views that were held by garden architects and others some fifty or sixty years ago. As shown by the gardening books of note that were published about the middle of last century and fruit rooms that are still in existence in some great gardens, it was held that the fruit room could not well be too dry and airy, and that structures in which provision was not made for a free circulation of air through them were regarded as quite unsuitable for fruit storage. In many cases the fruit room had a place in the upper part of a large building used for various purposes, and practically all that were specially built were provided with several windows, and fitted with stages of lattice work which had wide spaces between the bars, the object being to fully expose the fruit on all sides to the air. As provisions, such as double or thatched roofs or hollow or covered walls, were seldom made for the maintenance of an equable temperature, and the atmospheric moisture reduced to a minimum, the shrivelling of the fruit commenced early in the winter. As this shrivelling proceeded rapidly with the increase of temperature outside in February, much fruit that should have been at its best in March was quite worthless before that month had run its course. Very different views are now held as to the conditions under which fruit should be kept; and it is generally recognised by experienced cultivators that hard fruits, particularly apples, will remain in a sound state over the longest period when the temperature of the place of storage ranges between 40 and 45 degrees and there is a liberal percentage of moisture in the atmosphere. Then, with regard to ventilation there is a consensus of opinion that, instead of the free circulation of air which in the past was considered essential, sufficient air should be admitted from the outside, and no more, to maintain the atmosphere in a sweet state. "Take advantage of warm, dry mornings for ventilating fruits rooms," was the advice given by some of the old writers; but at the present time a writer who is really an authority on the subject will tell us that the ventilation should be given at such times when air can be admitted without appreciably raising the temperature. Such advice is sound, and should invariably be acted upon, for it is necessary, not only to prevent decay, but to check the evaporation of the juices upon which the value of the fruit depends. There is some difference of opinion as to whether the fruit room should be partly below the ground, or whether it should be above the surface, and the fact that there is a difference upon this point is a proof that, provided it is built in accordance with modern ideas, it is really of no consequence whether it is above or below the surface. Within recent years we have had opportunities for seeing a considerable number of modern fruit rooms, and the condition of the fruit in them was such as to show that this is really the case. Structures that are built above ground are the most convenient, and certainly the most desirable where large quantities of fruit have to be dealt with; and as evidence of the length of time that fruit can be kept in good condition in them, it may be mentioned that the exhibitors of the fine collections which are usually seen at the exhibitions and meetings of the Royal Horticultural Society in April and May store their fruit above ground. With regard to those built below the ground level it may be mentioned that we have for some years past utilised a spacious cellar as a fruit room with much success, and not so long since we saw in the North of England a fruit room that had been formed in a disused ice cellar, and had proved in every way satisfactory. The construction of a fruit room of the most approved description is not costly, as both design and fittings are of the simplest. A span-roof about twenty feet long and ten feet in height and width will store large quantities of fruit, and will suffice for the majority of gardens. The frame-work should be substantial and of wood, and both sides and roof be covered with $\frac{3}{4}$in. matchboards. The roof should have a thatch about fifteen inches in thickness, and this may be of reed, heather, or wheat straw, the relative merits of these materials being in the order in which they are placed. The sides and ends should be covered to a thickness of six inches of the same material as that used

MR. A. E. BURGESS.

for the thatch. The door should be well made, and fit close and have a sufficient width to allow a hand barrow to pass readily through it, and thus admit of the fruit being taken direct from the trees to the store. Necessarily, the central pathway should not have a less width. The shelves on either side may be twelve inches above each other, commencing at two feet from the ground level, and be formed with close-fitting boards or lattice-work, with narrow spaces between the bars. This is a matter of personal taste, as the fruit will keep equally well on each with a layer of clean wheat straw over the woodwork. An opening with closely-fitting shutter in the angle of the roof at each end will be required for the purposes of ventilation, and a window, fitted with a shutter, will be necessary for the admission of light when the fruit is being selected for use or examined for the removal of unsound specimens. It need hardly be said that the fruit should be gathered for storage when dry, but it is of some importance to state that it is not necessary to adopt the practice, still general, of arranging apples in single layers. Exceptionally fine specimens may be so disposed, but they will keep equally well placed two or three deep, and the late culinary varieties may be stored in layers from fifteen to eighteen inches in thickness, and preferably on the lower shelves. The most careful handling is necessary, even in the case of the hardest of the cooking apples, for if bruised they will not remain sound for any considerable period, and it is essential also that all fruits which have been bruised, or injured by birds or the larvae of insects, be put on one side for early use. To gather when the fruits have attained maturity as indicated by the pips assuming a brown colour is essential, and, speaking generally, it is better to lose a few fruits from falling than to gather the whole crop before it has reached the proper degree of ripeness. With regard to ventilation it will suffice to point to the fact that the admission of a moderate amount of air at rather long intervals will suffice to maintain the atmosphere in a satisfactory state, and that the ventilation should be done quite early in the day when the temperature is as nearly 40 degrees as possible.

Mr. Arthur E. Burgess, the Superintendent of School Gardening and Lecturer in Horticulture and Nature Study in Surrey, has for many years taken a prominent part in the work of horticultural instruction as conducted under the Educational Committees of various County Councils. He is a capable and enthusiastic teacher, and since his appointment to his present position in 1909 he has done a vast amount of good work. Mr. Burgess commenced the business of life at Messrs. J. Carter and Co.'s seed grounds at St. Osyth, and while with that firm he studied hard, and presently won a scholarship at the Essex County School of Horticulture. Here, in addition to studying and practising horticulture he underwent a long course of nature study, having already in view the profession of a teacher in these subjects. At twenty-four years of age Mr. Burgess had succeeded so well that he was appointed head gardener and assistant instructor at Chelmsford, and for about six years he had charge of over three acres of gardens, with a range of glass, and botanical, fruit, flower, and vegetable sections. It was in 1892 that he became Instructor in Horticulture and Nature Study under the Hertford County Council, and this appointment gave him his opportunity. Energetic and enthusiastic, and with a capital training for such a post, it was small wonder that Hertfordshire was sorry to lose him, when, in 1909 he migrated to Surrey, there to continue the work so ably begun years previously by Mr. John Wright, V.M.H. In the past two years he has given considerable time during the winter months to lectures and classes for school teachers, and, as a result of his work in this direction, about eighty teachers have obtained the R.H.S. Certificate; he hopes that before many years have passed all the teachers in the rural districts of the county will have qualified to teach school gardening and nature study. Mr. Burgess has 135 elementary school gardens to supervise, and in these gardens 2,600 scholars are receiving instruction, each having a separate plot; there are also fourteen groups of evening continuation classes, with about 190 pupils. From these few notes it will be gathered that Mr. Burgess' task is no light one, and that he is keeping up the high standard of horticultural education so long associated with the County of Surrey.

National Rose Society's Provincial Show, 1912.—We understand that at a meeting held on Tuesday last the Council of the National Rose Society unanimously resolved to accept the invitation that had been received from the local society to hold next year's exhibition at Belfast. The date, we learn, has not yet been fixed, but the show will probably be held in the third week in July.

Summer Bedding in Regent's Park.—The arrangements of tender and other flowering and ornamental-leaved plants in Regent's Park during the past summer were highly successful, and have been a source of pleasure to visitors throughout the season. As usual, Mr. A. D. Webster, the superintendent of this fine park, was careful in carrying out the arrangements to have them varied as well as tasteful, and the diversity of style has added much to the attractiveness of the general display, and greatly enhanced its educational value. Especially attractive have been the large groups formed chiefly with stove and greenhouse plants, for many of those from tropical regions, such as the acalyphas and crotons, have grown as freely as in the plant stove, and the leaf-colouring has been exceptionally rich. The quiet colouring of the bold group of succulents has been most pleasing, and the quaint forms of many of the plants have been a constant source of interest to the visitors not well acquainted with the varied forms of plant life. Cannas have been used freely, and with the aid of the high temperature that was experienced over so long a period, and it may be assumed liberal supplies of water, they grew vigorously and their richly-coloured flowers produced a fine effect. Fuchsias have constituted a distinct and beautiful feature, for the plants in beds and the specimens grouped on the lawn with the pots partly sunk in the turf have grown and flowered most satisfactorily. Altogether, the display is one that has fully maintained the traditions of Regent's Park for its summer arrangements of flowering and fine foliage plants.

Gardeners' Association for Midsomer Norton.—A meeting of gardeners and others interested in horticultural matters was held at Midsomer Norton a few days since for the purpose of considering the advisability of forming a gardeners' association. After a full discussion the meeting decided that it was desirable such association should be established, and proceeded to elect Mr. J. Boulter chairman, Mr. George McMurtie vice-chairman, and Mr. W. C. Scadding hon. secretary. It was further resolved that meetings should be held on the first and third Thursdays of each month, and that exhibits of plants, flowers, fruits, and vegetables be invited.

National Sweet Pea Society.—The next annual exhibition of this society will be held at the Royal Horticultural Hall, Westminster, on Tuesday and Wednesday, July 9 and 10, 1912.

Fungus Foray in Somerset.—The British Mycological Society, of which Professor E. S. Salmon is the president, held its fungus foray last week in West Somerset. At one of the evening meetings at Taunton, Mr. E. W. Swanton, of the Haslemere Educational Museum, gave an illustrated lecture on the fungoid diseases of fruit trees. He stated in the course of his lecture that the majority of the Somerset orchards were infected with fungi more or less injurious, and urged the importance of systematic spraying as a means of keeping the trees healthy. In the case of apple scab, which is so prevalent in all parts of the country, spraying would, it was suggested, result in the production of 99 per cent. of sound fruit.

National Chrysanthemum Society.—Mr. R. A. Witty informs us that the annual dinner of this society will be held at the Holborn Restaurant on Wednesday, November 29, and not on November 23, as originally arranged.

Victoria regia at Regent's Park.—Visitors to the exhibition of dahlias held by the National Dahlia Society in the gardens of the Royal Botanic Society Regent's Park, had an opportunity of seeing at its best one of the finest specimens of Victoria regia that has been seen in British gardens. For some years past this magnificent water lily has been grown in the Royal Botanic Society's gardens with quite exceptional success, but this year the specimen has attained so high a state of development as to surpass the plants of previous years. The specimen was raised from seed in February last, and has borne thirty flowers, and now covers the surface of the large tank with fifteen finely-developed leaves, which have a diameter ranging from six to eight feet.

The Mansfield Horticultural Society sustained a considerable loss on their show this year, and the Duke of Portland has generously forwarded through his agent a cheque to the secretary of the society for £24 1s. 3d. to balance the deficit.

Utility of School Gardens.—In speaking at Mains the other day on the nature and objects of school gardening, Lord Pentland pointed out that courses in gardening were not included in the school curriculum with a view to turning out full-fledged gardeners, and this fact, he thought, could not be too clearly stated. He wished to attack that prejudice, because he believed that was the last enemy in the way of development of school gardens. It was urged that all our boys and girls could not be gardeners, and the question was put—Why should they study gardening? It would require a treatise on the aims of education to give a complete answer to those objections, but he should like to point out that besides sowing the seeds of an enthusiasm that might be a recreation and a delight to the end of one's life, precisely as was a love of literature and books, a course of school gardening might be made an admirable discipline of character. Carried out with the right spirit, it would provide abundant openings for cultivating the powers of observation, and for exercising the qualities of care and patience. The reasoning faculty, too, would be called into play, although in a fashion less direct and obvious than that which one was accustomed to associate with some of the older school subjects. And lastly, it was not possible to imagine a training in gardening which was not also, in some measure at least, a training in good taste. It was not, therefore, on utilitarian but on general educational grounds that school gardening rested its claims to the consideration of those who were responsible for the framing of supplementary courses suitable to the needs of the locality in which a particular school might be situated. Its usefulness as an educational instrument would be enhanced in direct proportion to the degree to which it was interwoven with the rest of the work of the pupils. It should be founded firmly on the nature study which was appropriate to the Junior Division, and the numerous points of interest which it would suggest as it developed could readily be made to yield excellent results.

The Pruning of Fruit Trees was the subject of an instructive lecture given before the members of the Brighton Horticultural Society on the 20th inst. by Mr. F. Phillips, of Craigen-Dowie Gardens, Reigate. The several kinds of hardy fruit in general cultivation were passed under review, and the most suitable methods of pruning were described in a clear and essentially practical manner.

Wenatchee Peaches in London.—During the past week there have been on sale in London considerable quantities of peaches of foreign growth that have been of medium size, good appearance, and fair quality. These peaches had formed part of the large consignment of 2,000 cases that arrived at Covent Garden from the Wenatchee Valley in the State of Washington, on the 19th inst. This valley has for a long period been known for the high quality of its apples, and it has of late years obtained a considerable reputation for its peaches, upwards of 8,000 acres being devoted to these fruits. The fruits were carefully packed in cases, and the cases put in ice cars attached to the mail train and sent to New York, whence they were shipped to England. They were delivered in Covent Garden within thirteen days of the date of dispatch, a fact worthy of note, seeing that the distance covered was 3,000 miles. This is the first time American peaches have been placed on the London markets, although peaches from the Ontario orchards have been imported for some years past.

Glasgow Fruit Market. The Corporation of Glasgow has provided in the Bazaar a spacious fruit auction room for the purpose of giving increased facilities for the expeditious handling of large quantities of fruit. The seating provided consists of tip-up chairs, which rise from the floor level tier upon tier in the form of an amphitheatre, thus affording buyers an uninterrupted view of the sample lifts which are situated in the front of the auctioneer's rostrum. The room has ample accommodation for 500 persons, and it is hoped that the traders in fruits who have for some time past been advocating its provision will take full advantage of the opportunities it gives for the quick dispatch of business.

American Apple Crop.—In summarising a series of reports on the prospects of the fruit crop in America and Canada, the editor of "The National Nurseryman" states that it appears from the reports that the crop of winter apples is less this year than the crop gathered in 1911.

SUTTONS
G.M.1935

MESSRS. SUTTON AND SONS' GOLD MEDAL COLLECTION OF VEGETABLES at the Royal Horticultural Society's Vegetable Show, September 26.

NOTES FROM KEW.

Impatiens Kewensis.

To Kew we are within recent years indebted for many hybrids which have eventually proved themselves to be thoroughly useful, and this new impatiens is one that will probably in time be added to the list. It is the result of a cross between Impatiens platypetala, an old species introduced over 60 years ago from Java, and the comparatively new I. Herzogi, a native of New Guinea. The flowers of I. platypetala are of a bright rosy-lilac colour, while those of I. Herzogi are brilliant orange-scarlet. Strange to say, the union of these two has resulted in the production of a variety with bright crimson flowers with, in some instances, a magenta suffusion. Though the several plants now in bloom in the intermediate portion of the T range were all the product of a single pod, the flowers show a certain amount of variability in their colouring, some individuals almost suggesting the fairly well-known I. Hawkeri. In habit this new hybrid partakes more of the upright character of I. Herzogi than the spreading growth of I. platypetala. Being both an interesting and a pretty form, I. Kewensis will no doubt soon become generally grown. Should it not produce fertile seeds to admit of its wholesale propagation, cuttings will, no doubt, as in the case of the others, strike root very readily.

Clerodendron ugandense.

The clerodendrons are an extremely variable race, but this comparatively new species is in the colour of its blossoms a decided break away from any of the varieties in general cultivation. It is a free, loose-growing shrub, and in the cool portion of the T range associated with pelargoniums and various other South African plants it is just at home. Trained to a rafter it is seen to considerable advantage, the long, slender, leafy branches being terminated by loose racemes of blossoms. These are individually about an inch across, and are of a pleasing shade of light blue, except the lowermost lobe, which is disposed in the form of a lip, and is of a dark blue tint, thus affording a marked contrast to the rest of the flower. Being of ready propagation and simple cultural requirements this clerodendron should before long be more generally cultivated. It is, as implied by its specific name, a native of the Uganda district of Africa, and was first raised at Kew from seeds sent by Mr. M. T. Dawe, who collected them in a spot about 2,000 feet above the sea level. Judging by its behaviour at Kew it is essentially a greenhouse plant, and where it has plenty of light and air the flowers are better coloured than in a warmer and more shaded structure. In a fully-exposed position and spurred back it might be grown in bush form, but as a rambler for the roof or rafter it is certainly very pleasing.

Gerbera Jamesoni and Zephyranthes candida.

The custom that now prevails at Kew of placing at the entrance gates a notice of the different subjects of especial interest at the time is of great service to the casual visitor. In this list the gerberas and zephyranthes in the narrow border adjoining the orchid houses are mentioned, and deservedly bracketed together, as the two form a delightful and most uncommon feature. The gerberas are brilliant in their colouring, and as an edging thereto and a foil to their vivid tints we have the white crocus-like flowers of the zephyranthes springing from a dense tuft of deep green grasslike leaves. Such an effective combination as these two form is well worth going some distance to see.

Crotolaria capensis.

This leguminous shrub is a native of South Africa, from whence it was introduced in 1774. As flowering in the cool portion of the T range, it is certainly well worthy of note for the embellishment of the greenhouse at this season; yet, apart from Kew, and last year in Messrs. Veitch's nursery at Chelsea, I have not met with it so employed. It somewhat suggests a specimen of the Bladder Senna (Colutea arborescens). The leaves are trifoliate, and the flowers, which are borne in terminal drooping racemes, are bright yellow when fully expanded, but in an undeveloped state are tinged with green. It is a plant of easy culture, for cuttings are not at all difficult to strike, after which they will grow well in ordinary potting compost.

Oxalis Bowieana.

Many occupants of the greenhouse that have contributed to its embellishment for a long time are now past their best, and the question of their successors becomes an important item. A group of this oxalis in the cool portion of the T range shows well its value in this respect, the mass of large green trifoliate leaves forming in themselves a delightful feature, whose beauty is considerably enhanced by the profusion of rich rosy-red blossoms with which they are overtopped. This oxalis can be bought at a cheap rate, and its cultural requirements are simple, both of which are important matters in many places. In the Kew Hand List O. purpurata is given as the correct name of this species, but it is generally known as O. Bowieana, in fact, the term purpurata as applied to the blossoms is a misleading one.

Cæsalpinia Gilliesi.

The specimen of this cæsalpinia trained to the front of the Museum No. 2 is this season unusually floriferous, probably owing to the great heat we have experienced. Out of flower this cæsalpinia suggests a rather attenuated specimen of Acacia lophantha, but when in full bloom it is a really striking object. The flowers, which are borne in large terminal racemes, are bright yellow, and each has a cluster of long, prominent bright red stamens, thus yielding a startling contrast in colour. The Kew plant has this year about 50 flower clusters, either expanded or approaching that stage. Cæsalpinia Gilliesi is a native of Mendoza, South America, and is said to have been introduced in 1829. The Kew specimen has been in its present position, and flowered more or less freely, for several years. It is a near relative of the Royal Peacock Flower (Poinciana regia), which is so much admired in tropical countries; indeed, cæsalpinia is sometimes included in the genus Poinciana. K.

ORNAMENTAL CRABS.

The various kinds of crab apples form an interesting and showy feature in gardens during the autumn, for in many instances the fruits are highly coloured, and they are usually borne in sufficient numbers to create a good display. In some parts of the country the common crab, Pyrus malus, is found wild about fields and hedgerows, but its rosy-cheeked fruits, though showy, are less ornamental than those of various other species and hybrids. There are several distinct varieties of P. malus, which are of more decorative appearance than the type, and those are to be commended for garden purposes. Unfortunately, it is not possible to use the best of the crabs satisfactorily in public gardens, for the fruits offer such an attraction to children that trees are frequently damaged, and sometimes ruined, during raids on the fruit. There are, however, other gardens where they may be grown, and, in addition to the beauty of the fruits, they are useful for making into jelly, while a few are distinctly palatable when raw.

One item must be borne in mind respecting the culture of these trees, for, like the apple, all the members of the malus section of Pyrus are attacked by American blight, and if a sharp look-out is not kept, and means taken to check it when it first appears, the health of the trees may be seriously imperilled. Any garden where the ordinary apples give good results may be expected to be suitable places for the culture of the crabs, while, given loamy soil they generally grow vigorously.

Pyrus malus is well known by reason of its pretty delicate pink and white flowers in spring and its applelike, red and green, rather bitter and very sour fruit in autumn. The variety astracanica is the parent of the Red Astracan apple, and is recognised by its intensely red fruit. It is a desirable variety for general cultivation. Coccinea, another kind noted for its red fruit, is also a showy variety of P. malus, while Bertini, flexilis, pendula, and rosea all bear showy fruits. P. malus flore albo pleno differs from other kinds by having semi-double white flowers: a few fruits of a yellowish colour are borne, but they have no great pretensions to beauty.

Pyrus baccata, the Siberian crab, is a well-known decorative tree, whose fruits are esteemed by cooks for making into jelly. Its red and yellow fruits are round, hard and glossy, and they are about three-quarters of an inch in diameter. The fruits are not troubled much by birds, and it is not uncommon for them to hang on the trees until mid-winter, whilst they have been noted as late as March. There are several well-marked varieties, which are distinguished either by shape, size, or colour of the fruits. Thus, cerasifera has red cherry-like fruits, and xanthocarpa yellow fruits.

P. prunifolia, a Siberian species, very closely allied to P. baccata, is also a very ornamental tree. So far as habit, flowers, and foliage are concerned, it is very difficult to distinguish the two species, but a well-marked difference is noticeable in the fruits, for whereas in the case of P. baccata the calyx lobes are deciduous and the apex of the fruit forms a small hollow, in P. prunifolia the calyx lobes are persistent and terminate the fruit, as in the case of the apple. It is prolific in varieties; cerasiformis and fructu coccinea are two of the more showy kinds, the fruit being of a rich red colour.

The curious red fruits of P. Niedzwetzkyana have been very noticeable this year. They attain a length of two inches, and are wide in comparison. The deep red colour of the skin is noticeable, not only to the centre of the fruit, but is also found in branches and roots.

P. coronaria, the American crab apple, differs from P. malus in bearing small fruits, which, when ripe, are a vivid shade of green. It is not included among the more ornamental kinds, and, so far as flowering is concerned, its variety flore pleno is far in advance of it. P. Ringo is a very beautiful Japanese crab. It very rarely fails to bear a good crop of fruits, which, when ripe, are of a rich orange colour. P. sikkimensis differs from all the other kinds in general appearance, for its rather small fruits are borne on long slender stalks, and bear very long calyx lobes. The colour is dull red and green.

Such beautiful flowering kinds as P. spectabilis, P. floribunda, and P. Scheideckeri are less showy in autumn than those already mentioned, and they would hardly be planted for the sake of their fruit. There are, however, several other large-fruited crabs which have been raised by hybridists, which are exceedingly showy. The fruits are as large as those of small apples. All may be used for jelly-making, whilst some are eatable. Good ones are John Downie, Dartmouth, Victoria, and Imperial, with red fruits, and Transparent, Transcendent, The Fairy, and Mrs. John Seden with yellow or red and yellow fruits. These are all well worth conspicuous positions, for the fruit is very highly coloured, and, as a rule, a good crop is borne. W. DALLIMORE.

The Aperture of Stomata.—With the object of estimating the aperture of stomata, Dr. Francis Darwin, assisted by Miss D. F. M. Pertz, has devised an ingenious apparatus that he calls a porometer. It consists, according to "Nature," of a small campanulate glass vessel attached to an air chamber. The glass vessel is fixed to a leaf, and pressure in the chamber is reduced, whereby air is drawn through the stomata. The rate of flow of the air into the chamber is measured, and supplies a comparative indicator of changes in the apertures of the stomata. The porometer provides a continuous method; it indicates the movements of a group of living cells, and possesses a great advantage over the horn hygroscope and cobalt paper, inasmuch as the readings of the instrument are independent of transpiration.

NEW PLANTS, ETC.

DAHLIAS.

Diadem.—A large collarette variety with rather pointed ray florets of a beautiful rose-pink shade: the collar florets are white. A very attractive form. F.C.C., N.D.S., Sept. 20. Messrs. Dobbie and Co., Edinburgh.

Leitstern.—This is a rather small collarette dahlia, with deep crimson pointed ray florets, and a very highly developed set of white collar florets that form quite a frill round the yellow disc. F.C.C., N.D.S., September 20. Messrs. Dobbie and Co., Edinburgh.

Golden Wave.—A large cactus variety of first-rate exhibition form, and of a pretty soft shade of golden-yellow. F.C.C., N.D.S., September 20. Messrs. Jas. Stredwick and Son, St. Leonards.

Frederick Wenham.—This is a particularly large and handsome cactus dahlia, with incurving florets. The colour is warm fawn-pink, with soft salmon glow at the centre. F.C.C., N.D.S., September 20. Messrs. J. Stredwick and Son, St. Leonards.

Florrie Wells.—A showy and finely formed cactus variety, with stiff, pointed florets. The colouring is a pleasing combination of crimson and purple. F.C.C., N.D.S., September 20. Mr. H. Shoesmith, Woking.

Sunlight.—A good name for a long and stiff-stemmed garden cactus dahlia; the flowers, freely produced well above the foliage, are of medium size and good form, and the colour is a bright combination of yellow and orange. F.C.C., N.D.S., September 20. Messrs. Jas. Stredwick and Son, St. Leonards.

SPIRÆA VEITCHI.

This very handsome spiræa somewhat resembles S. canescens. One of the features of this Chinese shrub is that all the flowering twigs on a branch become erect, and each carries its head of white flowers into the same plane as its neighbour does, and so a long branch becomes, so to speak, one beautiful inflorescence. The species grows to a height of 10ft. or 12ft., and was discovered by Mr. E. H. Wilson. At Kingston this spiræa has proved quite hardy. Bot. Mag., t. 8,383.

DRACOCEPHALUM ARGUNENSE.

A perennial herbaceous plant that grows about 2ft. high, and bears violet white-spotted flowers in whorls grouped in a terminal raceme. Each flower, of pentstemon-like shape, is about 1½ inches long. Bot. Mag., t. 8,384.

CHICORY.

This easily-grown plant is invaluable for winter salads, and if seeds were sown, as is customary, early in May, large roots, with a considerable amount of top growth, will now be in evidence. Owing chiefly to the long-continued warmth seed stems may be more than usually prevalent. All such should be pulled out, thus giving more room for the plants remaining, and the soil about them be kept clear of weeds. The roots must remain where growing until the foliage shows signs of dying off, when slight disturbance with the spade will facilitate this process. Later supplies may remain in the ground until wanted, the roots being quite hardy.

To obtain stout, well-blanched heads slight warmth, and a dark position, are necessary. The roots, when raised from the open ground, may be reduced in length if desired, and have every vestige of summer foliage removed. Place the roots in moist earth in a box or other receptacle that will exclude the light, in a temperature of about 55 degrees. Growth is slower at first than later in the season, until, in spring, an upturned box in the open air is all that is required to induce growth and the necessary blanching.

J. Day.

SECONDARY GROWTH IN CATTLEYAS.

A correspondent writes that he has, unfortunately, not been able to prevent a number of his plants of Cattleya Loddigesi, C. labiata, and C. Percivaliana from making secondary growths on "leads," and he asks whether it would facilitate flowering if these new growths, now about 1½ inches high, were pinched out.

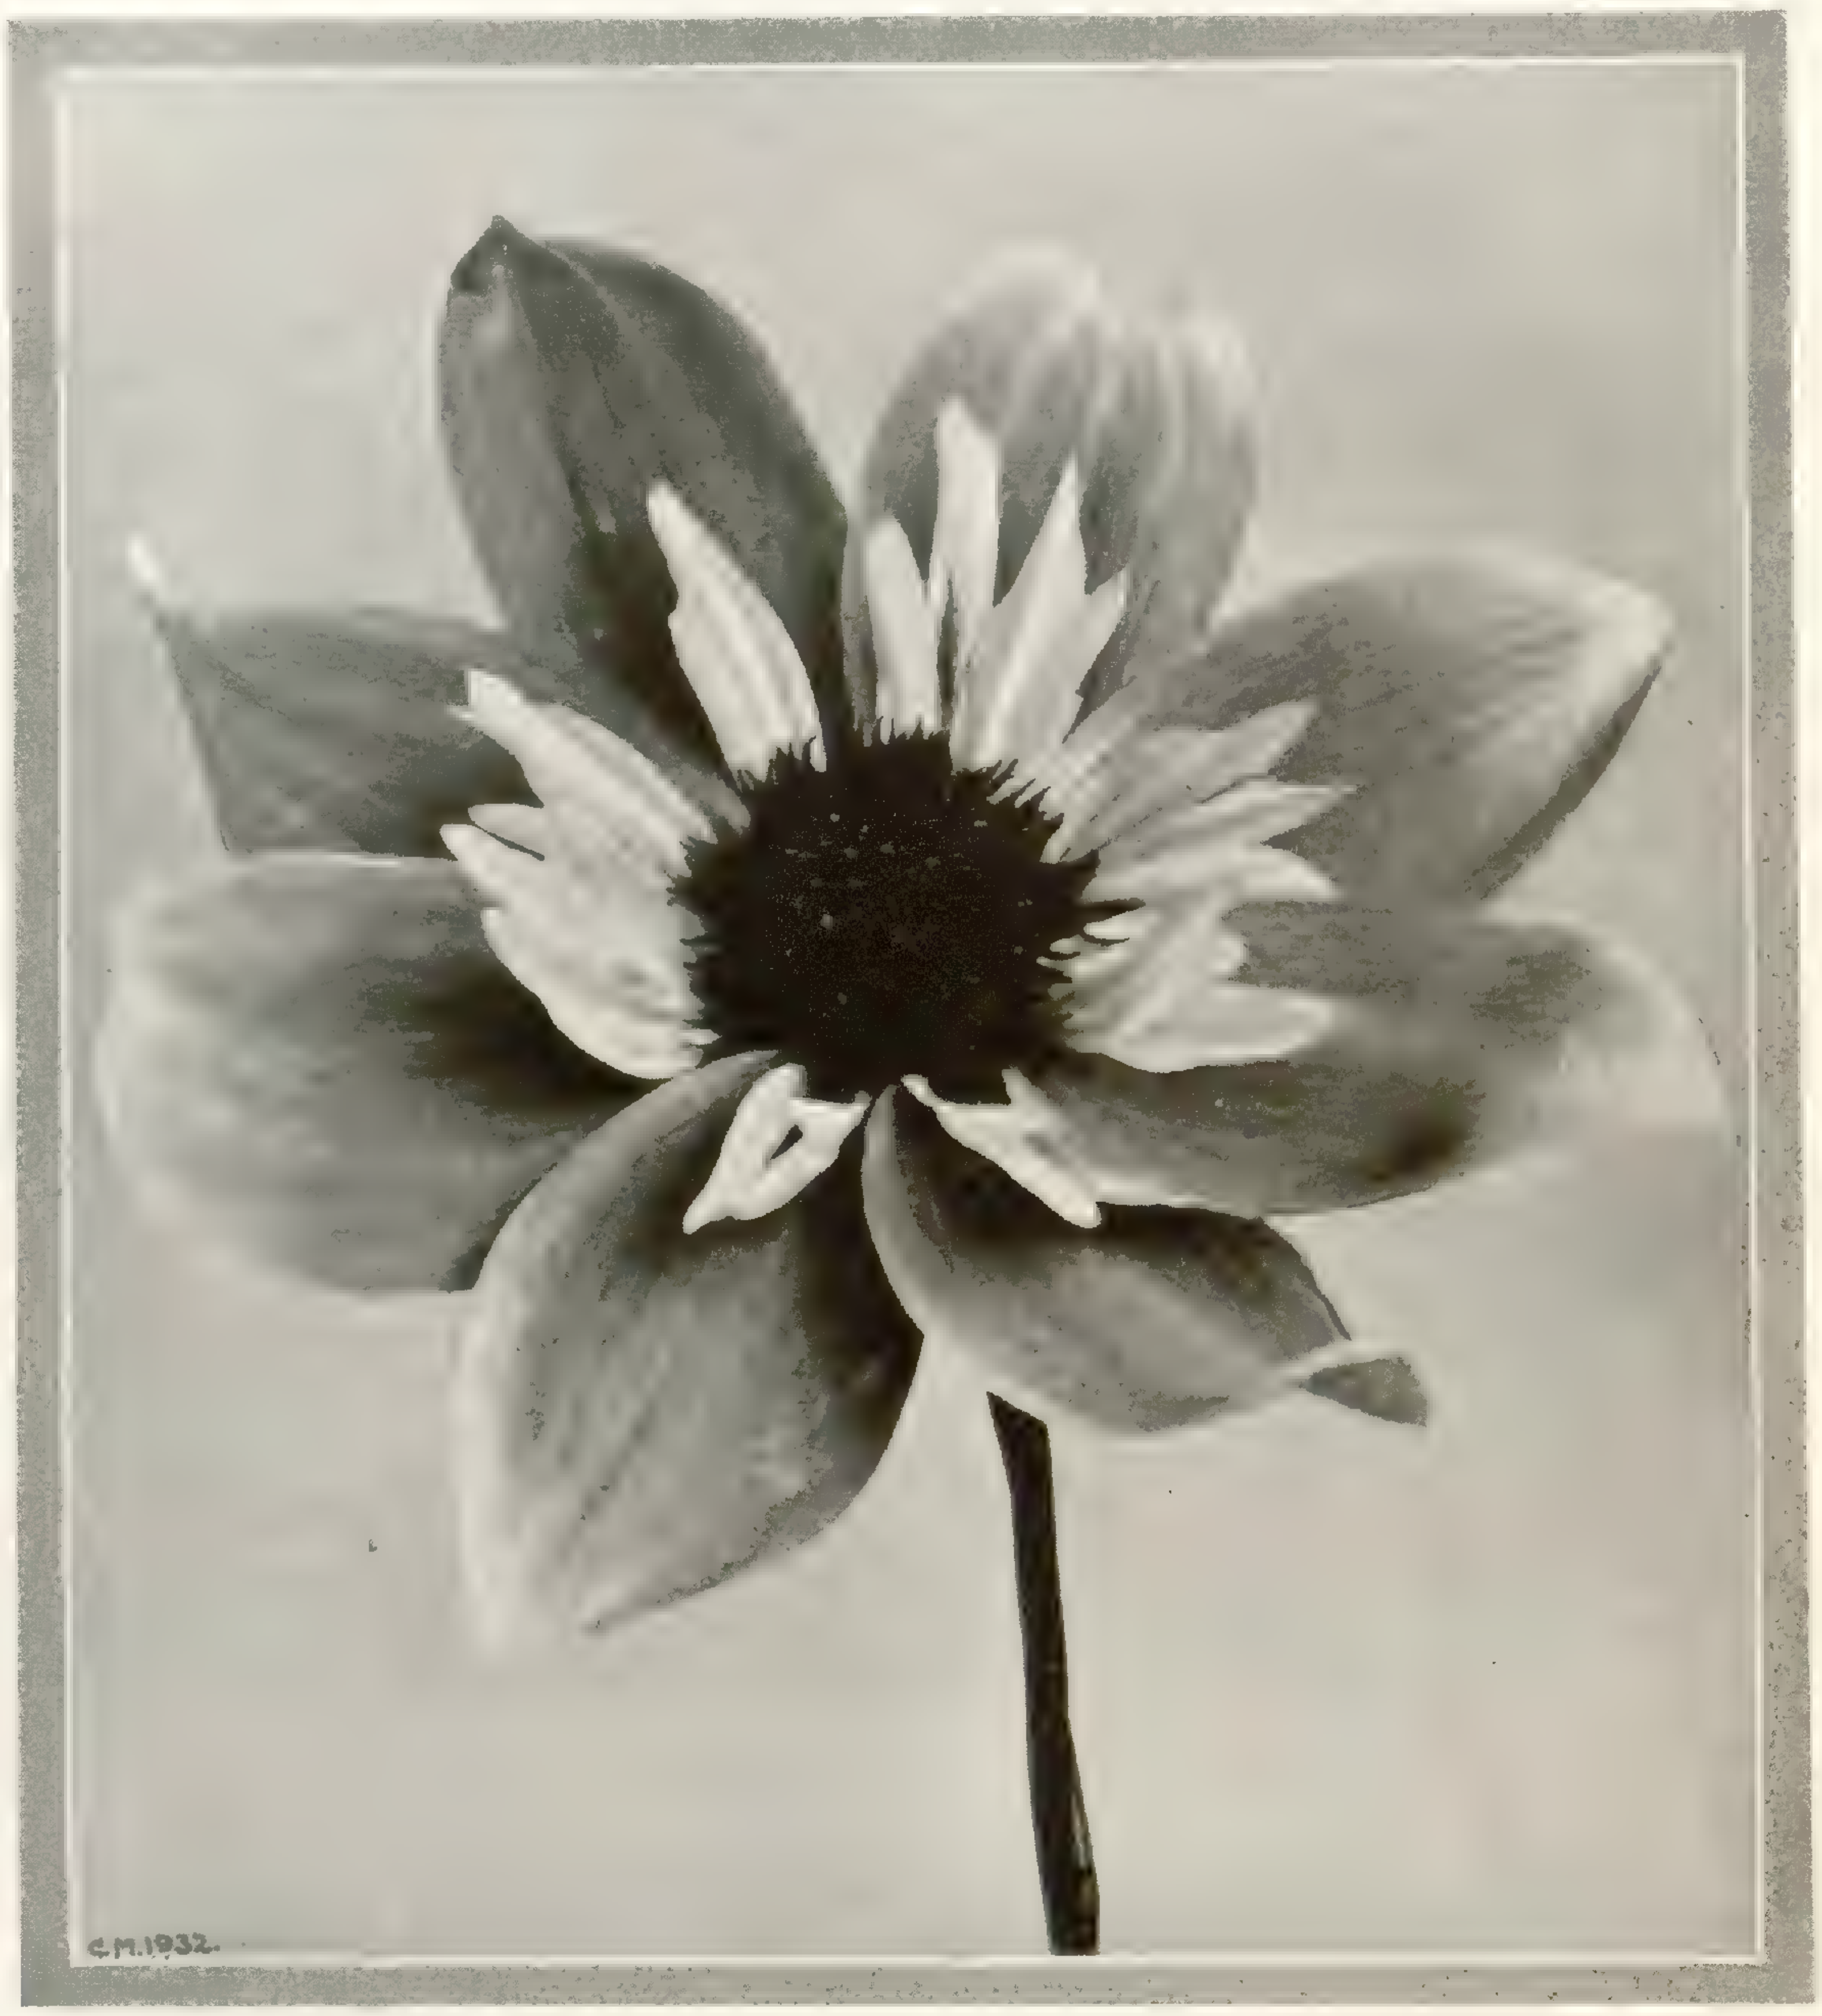
The subject of secondary growth is an interesting and important one, and the cattleyas mentioned are particularly liable to produce such growths, and in my notes to the Gardeners' Magazine I have frequently referred to the matter in the past.

Secondary growth may be attributed to more than one cause. If the plants are imported ones, excess of vigour, combined with a rapid growth generally induces secondary breaks to appear. The want of light (too much shade being used), combined with a hot, moist atmosphere, produces a large, sappy first growth, and the subsequent undesirable conditions referred to. The whole cause may be summed up as insufficient maturity or ripening of the pseudo-bulbs.

It is necessary with practically all summer-growing cattleyas to pay particular attention to the completion of growth, and if growth is too early, and there is a possibility of secondary growth commencing, it is advisable to place the plants in more exposed positions, where there is a drier and cooler atmosphere. I have known instances in the South of England where some cultivators of Cattleya gigas have suspended their plants under the trees in their garden during late summer to prevent secondary growth. While not advocating such a course one may say that some method of retarding must be devised whereby, while assisting the proper ripening and maturing of the seasonal growths, one may also prevent the secondary growth commencing. The cattleyas mentioned by my correspondent should not have their young growths cut away. The best method is to place the plants in the warmest and lightest place available, so that every encouragement is given to rapid development while there is time to obtain some benefit from the sun's rays. If the growths are retarded now, it becomes a far more difficult matter to deal with young growths later on, in November and December. There are about six weeks left during which some assistance may be looked for from the outside conditions, but there is very little movement in plant life after that until the turn of the year; during this dull and quiet period one has to be particularly careful to keep the plants supplied with just sufficient moisture to keep them plump, any excess of moisture causes damping and blackening of the bracts at the base of the growth.

I would advise my friend to keep his plants which have matured their growth as free from root moisture as possible, and place them in a light position at the coolest end of the house. He will find that the moisture in the atmosphere will be almost enough to keep the foliage and bulbs plump and healthy.

H. J. Chapman.



NEW COLLARETTE DAHLIA DIADEM.

Blooms rose-pink and white. F.C.C., N.D.S., September 20. Messrs. Dobbie and Co.

LILIUM HARRISI.

When bulbs of this lily were first sent here from Bermuda, now nearly thirty years ago, an immense amount of interest was centred around it, for it was by some claimed as a distinct species. Time has, however, altered this opinion, and it is now proved to be but a form of the Japanese Lilium longiflorum. From the fact that in the climate of Bermuda the bulbs ripen sufficiently early for them to reach this country by the end of July or early in August, Lilium Harrisi can be had in bloom much earlier than bulbs from Japan, unless these last are retarded, and it must be borne in mind that when L. Harrisi was first sent here retarding was not then practised.

The bulbs from Bermuda are in nearly every case packed in fine stone dust, which, being dry, and of an absorbent nature, takes a good deal of nourishment from them if they are allowed to remain therein too long. For this reason the bulbs should be obtained and potted as early as possible, otherwise they will suffer a good deal. By the time they reach this country the bulbs will have been dormant a long while, and the basal roots are ready to start away at once directly they are placed under conditions favourable to growth. As Lilium Harrisi from the Bermudas became so popular, owing to its early-flowering qualities, the name was, in time, for trade purposes, applied to the Japanese bulbs, which, though they may not be botanically distinct from the others, are grown under such different conditions that they cannot be had in flower till a much later period than L. Harrisi itself; in fact, the Japanese bulbs do not reach here till months afterwards.

As the retarding process is now so generally followed, and Japanese-grown bulbs readily lend themselves to this treatment, there is a large demand for them, but, still, Lilium Harrisi from Bermuda is appreciated by many who depend upon it for their earlier displays.

W. T.

HIBISCUS SYRIACUS.

Your correspondent, "G.B." (page 577), appears to be acquainted with only one form of this hibiscus, and that with double blossoms, whereas there is really a long list of garden varieties, in some of which the flowers are single, and others double. Personally, I prefer the single kinds, but that, of course, is only a matter of taste.

One of the most striking of all is flowering just now in many places with great freedom. This is the variety Cœleste, with large single blossoms of a very pleasing shade of dark lavender-blue with a reddish metallic suffusion in the centre. The typical Hibiscus syriacus bears single flowers, in colour white, or nearly so, with a crimson blotch at the base of each segment, thus forming a coloured centre to the flower. The variety Painted Lady is a very good form of this type. Another single flower, with pure white blossoms, is Totus albus, quite distinct from the others previously mentioned.

The double varieties in cultivation are very numerous, different shades of purple, red, pink, and blush being represented among them. Though wanting in a few most of them possess the dark-coloured centre in a more or less pronounced degree. A very fine pure white variety, with double blossoms, is Admiral Dewey, of transatlantic origin. There are varieties with variegated leaves, but at the time of the year the blossoms are produced the variegated portions of the foliage, especially during a hot summer, is apt to become discoloured, hence they are less effective than the green-leaved kinds.

This hibiscus is a very old plant in gardens, having, according to the "Dictionary of Gardening," been introduced in 1596. Even as long ago as Loudon's time no less than seven varieties were mentioned. It may be noted that this hibiscus was formerly known as Althæa frutex, and as such it is still occasionally met with in catalogues. Although bearing the specific name of syriacus, it has been questioned if this hibiscus is a native of Syria, or whether it originally came from the farther East. In this country, as stated by your correspondent, it prefers a well-drained warm soil, for in damp, cold districts it is not satisfactory. Some of the single kinds ripen seeds freely, but the progeny is more or less variable. I was once very interested to see in a French nursery a vast number of the different varieties of this hibiscus, every one of which was grafted on to seedlings of the common kind, and plants from eighteen inches to two feet high were sold at a very cheap rate.

W. T.

GARDEN NOTES FROM EAST ANGLIA.

Readers of the GARDENERS' MAGAZINE will doubtless store away in memory, or notebook, many items and incidents in connection with the record-breaking summer of 1911. And in this they will be justified.

A few notes from the driest part of the East Coast may be of interest, if only for the purpose of a brief comparison with the preceding year.

With reference to annuals: They have been shorter in duration than usual, owing to the great heat and lack of moisture. Sweet peas were very good for a fair period, and retained their colours well, partly owing to a position which broke the fierceness of the morning sun, and partly to deep cultivation. Stocks, of which we grow a goodly number, have succeeded beyond expectation. Frame-raised and transplanted varieties are at the moment of writing passing their best, but those sown in the borders where they stand are now at their zenith, really grand, almost, if not quite, up to the high standard of 1910, when these flowers were really exceptional. Nemesias have been disappointing, except in half-shady places, where they are still in bloom. In a fairly moist season these charming annuals reach a high order of merit, but in a year of drought they cannot be regarded as dependable plants.

Antirrhinums have been really good, both in growth and blossom, and further emphasise their value for a dry year or a dry position. Asters were good where the beds have been thoroughly worked, but those who did not attend to this point lacked the strong plants necessary to the production of good blossom. Pentstemons from seed are in flower, though not so fine in spike as last season; yet many of the forms are very pleasing, those of the Gem type being the most interesting. Among these latter are some good pure whites, which will another season be used for bedding.

Brachycome iberidifolia in variety, and Linaria maroccana have been consistently good, and both are worthy of greater appreciation. Annual statices have done better this season, the individual plants being of fine size and the blossoms most profuse, evidently approving of the dry conditions. Delphinium Belladonna, treated as an annual, is quite a success, fine free spikes of blossom being plentifully produced at the present time. D. Blue Butterfly, however, has been severely treated, though some of last year's seedlings, planted on a sloping bank, passed through the winter unharmed, and have made fine patches of deep gentian-blue.

Several other plantings of annuals, Virginian stocks, clarkias, etc., etc., have been short-lived, in spite of a good early growth. As we use breadths of annuals to carpet shrub and tree plantings we have felt this shortness of duration, but console ourselves with the reflection that probably another season will be less dry and exacting. Verbenas have afforded another instance of success. By making a careful selection from a good strain last season we have secured a pleasing range of colourings, which have done grandly. These, when reselected, will give grand material for next year's use. It is distinctly pleasing to see these old-fashioned favourites still being improved, and more widely grown.

Leaving the annuals for perennials, a few especial points intrude upon the notice. Michaelmas daisies are from ten days to a fortnight earlier than last year, and the same may be said of early chrysanthemums, both groups having made good growth for the season, and the cooler weather will ensure good blossoms upon the latter. Delphiniums are giving a good supply of secondary spikes, which, if not so tall, yet are certainly better than the main display, but it is noticeable that the spring-raised stock is far superior in the matter of continuous flowering than established plants. The value of some seedling varieties of Moon Daisies (raised from the variety Mrs. Lowthian Bell) is apparent at the present time, for while all of the established groups are out of blossom, the seedlings are just coming into full beauty. Gaillardias have been very good, and are still gay, the many fine forms of G. grandiflora being extremely decorative, and very useful for cutting.

Anchusa italica Dropmore variety is another plant which should be renewed as time goes on, for young plants are of greater value, and give a much longer display than old ones. Montbretias are now in evidence, and make a gay picture, but they are not up to the usual high standard unless planted by the waterside, for they suffer severely from drought. Germania is one of the most effective of the year, and the brilliant Lutetia is also very noteworthy. The yellows, George Davison, St. Botolph, Lady Hamilton, etc., are also very good. Gladioli have in the main been good, but in the great heats the blossoms faded very quickly, so that one obtained but a fleeting reminder of their real value for garden decoration. Gauras are again good, and the same remark applies to Artemisia lactiflora, the growth of the vernonias, and eryngiums, and echinops.

In the pools the nymphæas have given a record display of blossom. Throughout the display has been continuous, and at the moment of writing bud and blossom seem more profuse than ever. It would be difficult to choose the most effective water-lilies of the season, but Chromatella, Lucida, James Brydon, Seignoureti, Marliacea albida, Carnea, Rosea, and Colossea are among the most floriferous. Villarsias, nuphars, sagittarias, and a host of other subjects in the waterways have made record growth, while waterside plants generally have given no cause for complaint, save for the rapid passing of blossom time in some of them.

P. S. HAYWARD.

BULBS.—A practical treatise on the cultivation of hardy, hothouse and greenhouse bulbous and tuberous rooted plants is "BULBS AND THEIR CULTIVATION," by T. W. Sanders, price 2s. 6d. net, or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

BORDER CARNATION NOTES.

Growers of border carnations will now be rapidly pushing forward their autumn work. The making-up of new beds and plantations to accommodate the rooted layers must be the first consideration. If not already prepared, the work should be quickly done, thoroughly digging the whole and incorporating a moderate dressing of decayed manure (preferably cow manure), together with turfy loam, crushed bones, and sand.

If insects are troublesome, a scattering of a soil insecticide previous to the digging, will alleviate the trouble, while for heavy ground there is nothing better than a quantity of wood ashes or mortar rubble to assist in lightening and sweetening the soil.

Autumn planting I believe to be far preferable to wintering them in pots and planting out in early spring, but on this point growers must follow their own ideas, for it is somewhat difficult to winter some varieties in the open ground in certain districts. Growths were very hard, and rather over-ripened at the time of layering, but this has not affected their rooting capacity, and we have been practically free from loss, and at the moment of writing —September 20—all varieties seem to be well rooted. The carnations are short in growth, but beautifully healthy and vigorous, and give promise of better material than ever for the next season's display.

The only trace of disease we have is in two or three seedlings, which have the rust, a disease which the general stock have not shown the least trace of, and which is hardly ever noted among border varieties. My old theory, that this disease can be transmitted from one generation to another by the seed alone, I hold as of yore, and I would advise growers, if they have infected stocks, not to save seed from them, but rather to do all they can to eradicate the disease.

It should be remembered that work done now is of the utmost importance for the success of next season's blooms. All work must be thorough. Sever the layers cleanly, using a keen-edged knife. A good cut heals infinitely quicker and better than a bad one. Make the beds moderately firm, and plant firmly. Loose planting has resulted in many carnation losses, and the grower must particularly avoid it.

It is well to study the effect of the varieties. A good arrangement as to colour and height will be far more telling than a haphazard planting. Plenty of space for development must be allowed. Good varieties should always be given the preference over weaker or less attractive ones, and a good collection is only built up by good selection and keeping the plants in robust health.

A few words concerning varieties worth growing may perhaps be acceptable to those just commencing a collection. Yellow grounds are given a high place nowadays, but one must also secure sufficient selfs and fancies in other colourings to ensure a wide range of beauty.

Charming novelties are Mrs. Henwood, a lovely white of perfect form; Mrs. Robert Berkeley, an exquisite self in apple-blossom pink; Lass of Gowrie, a pretty fancy, white marked with red; Forester, a fine yellow ground marked with red; Ilene, a superb white, with a distinct blush shading; Amazon, a glorious orange-buff, suffused with scarlet toning; Maggie Morton, pure white, marked with bright rose; and Mrs. Penton, a fine buff variety, heavily marked with rose. Very fine, too, are Chocolate, a good form in its "name" colour; T. E. Henwood, a bright salmon-pink; Mrs. Geo. Marshall, a splendid rich crimson; Lady Roscoe, a first-class blush white; Daffodil, doubtless the finest yellow in existence; Cardinal, a glowing scarlet of perfect form; Robert Bruce, a grand apricot self; Sweet Briar, white, marked with lavender and rose; and Kate Nickleby, a large pure white.

Lack of space forbids an extended notice of many fine carnations. But those who plant Agnes Sorrel, Ashantee, Banner, Benbow, Bob Acres, Ellen Douglas, Elizabeth Shiffner, Heather Bell, Helen Countess of Radnor, Hercules, King Solomon, Kissing Cup, Liberté, Miss Willmott, Miss Maud Sullivan, Mrs. Robert Morton, Pasquin, Purple Emperor, Sam Weller, Trojan, Sir Galahad, and Splendour will have the basis of a first-rate collection.

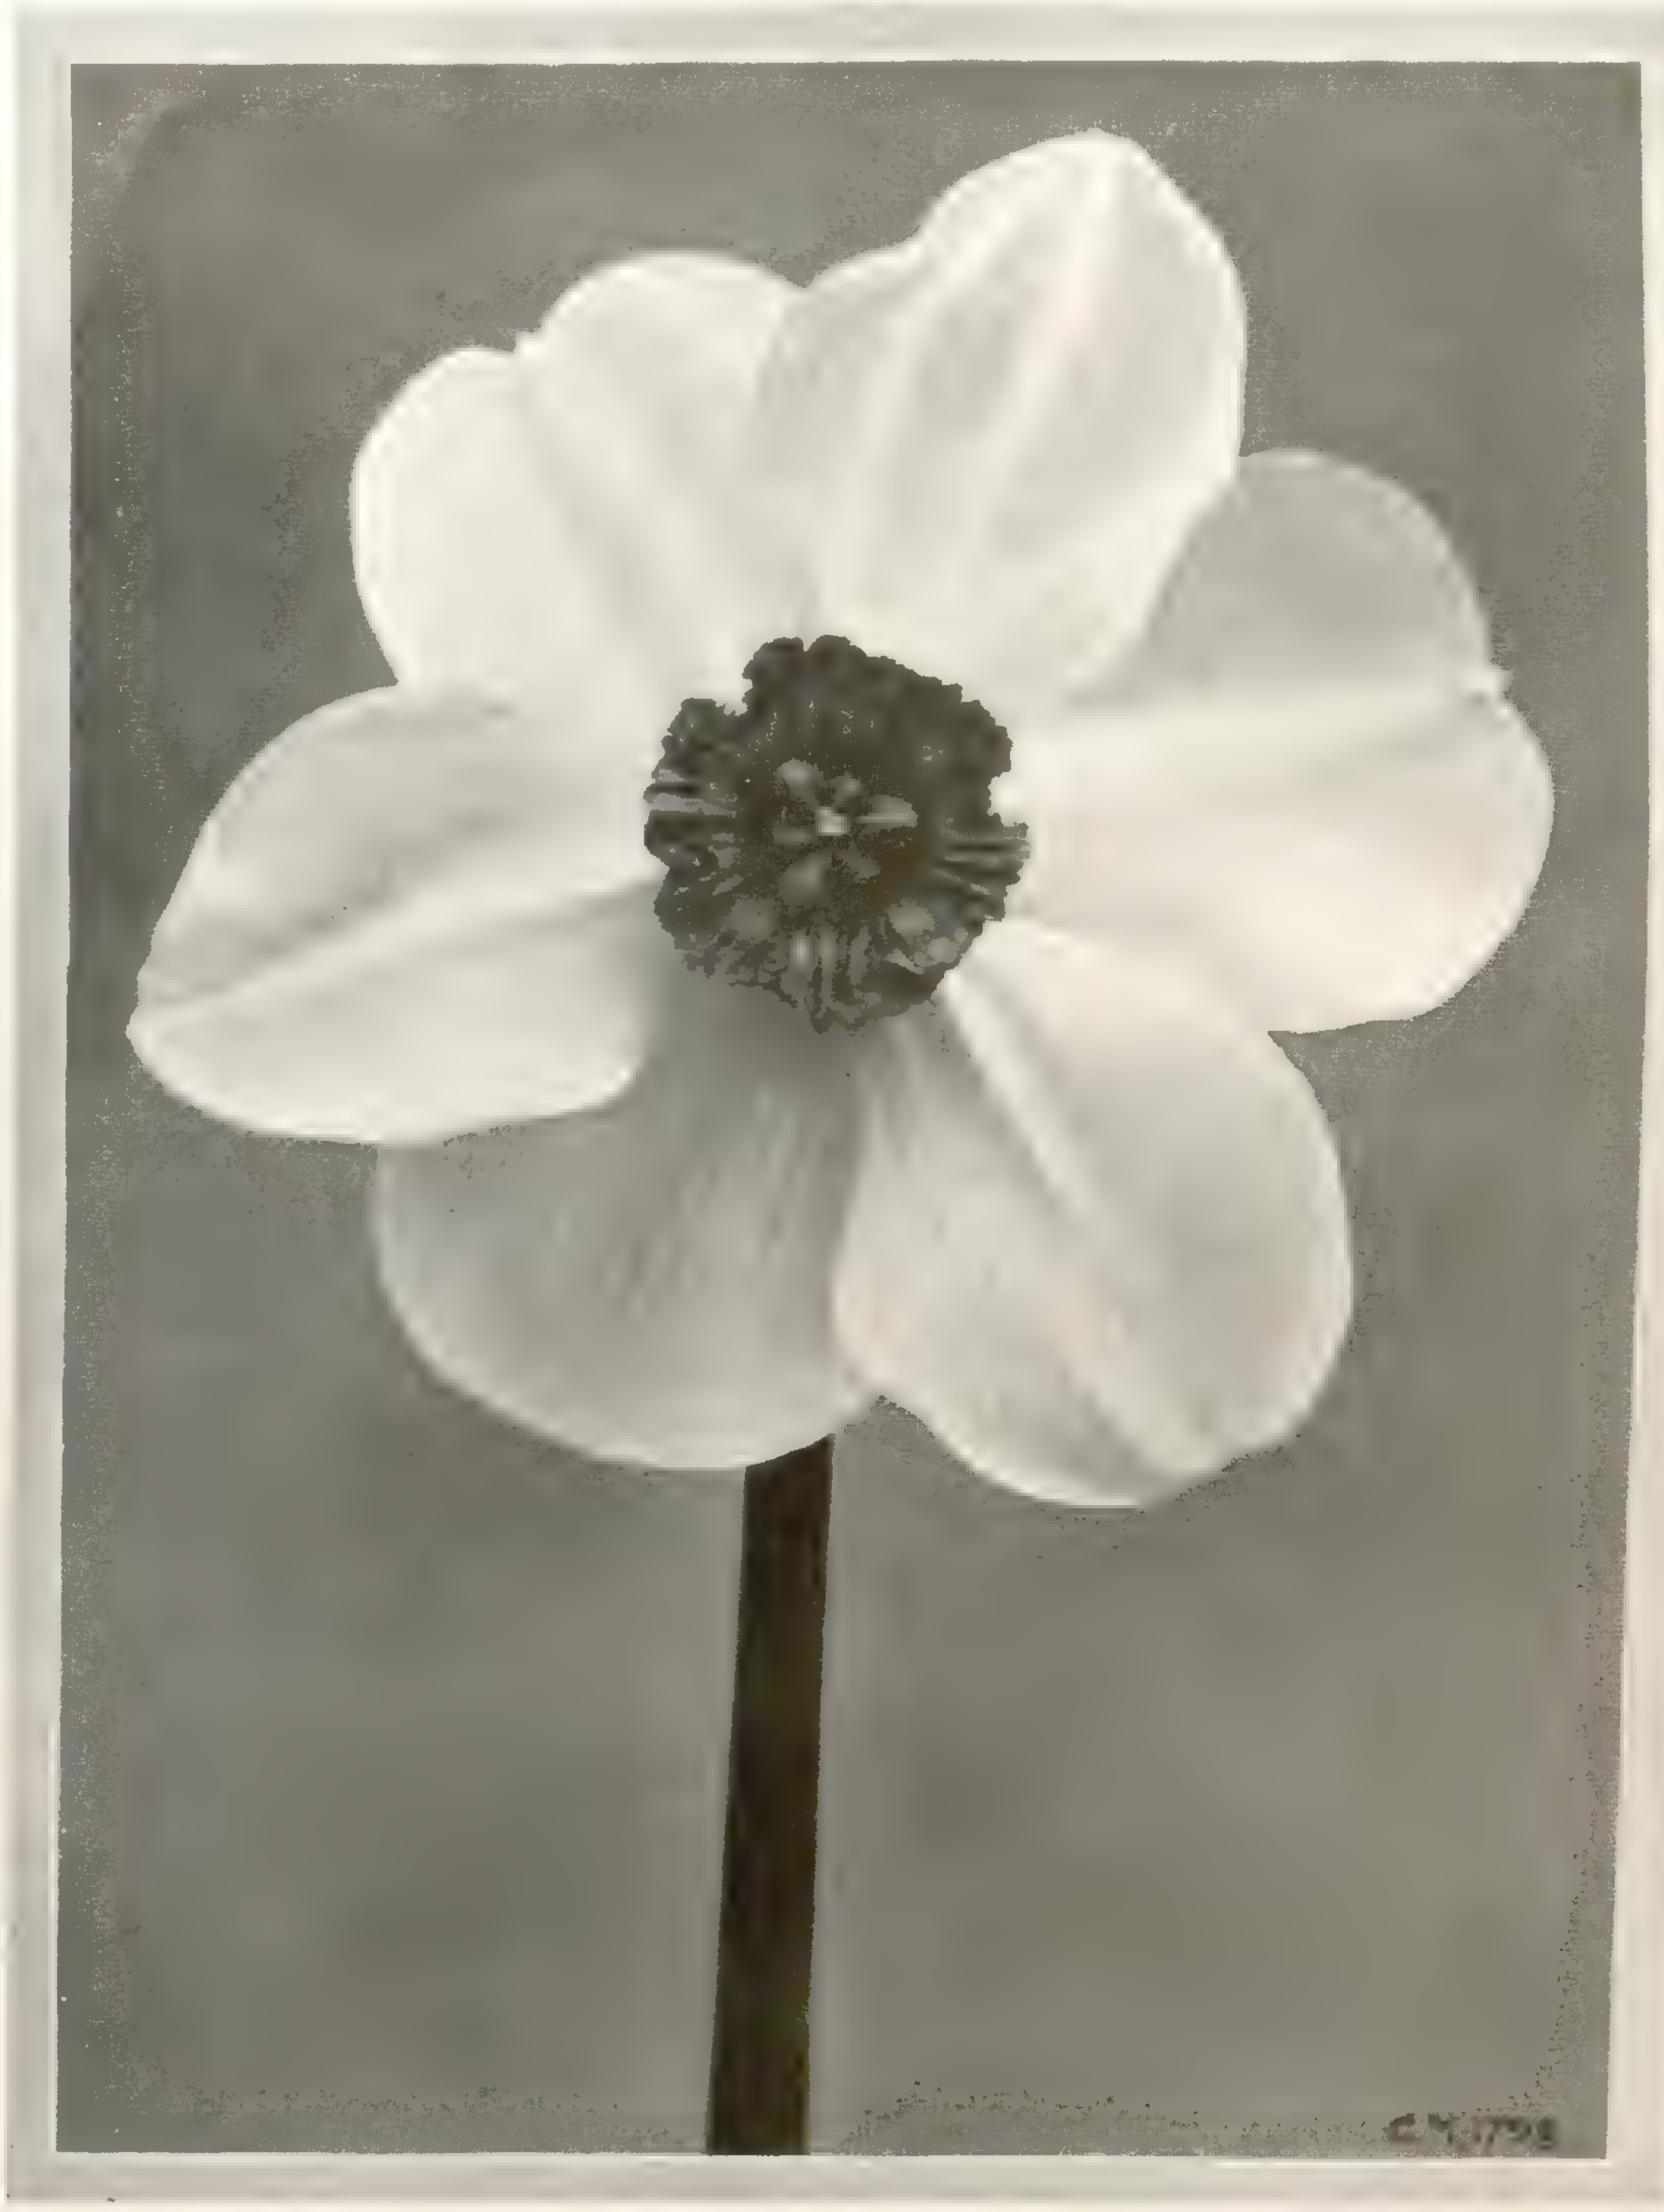
Apart from a little trouble with rust, the necessity of keeping a close look-out for insect pests and the inevitable rabbit in some districts, I think that carnations will give the grower very little anxiety this season, as stocks are so exceptionally clean and the soil is yet warm for planting. With a little showery weather after planting, the carnations will be given a good start, in readiness for the winter's rigour and cold.

Finally, it is important that all carnations be properly labelled, as this keeps the collection in perfect order, and adds to the interest from a visitor's point of view.

H. C.

NARCISSUS SOCRATES.

Another fine new Poet's Narcissus is Socrates, a variety that has received well-merited awards from the Royal Horticultural Society and at the Birmingham Daffodil Show this year. It is in the hands of Messrs. Barr and Sons, of Covent Garden, who exhibited it finely in the spring. The solid white flowers measure three inches across, and the segments overlay so as to form a bloom of great beauty and fine form. The cup, or crown, is deep yellow, with an unusually wide border of dark rich crimson-scarlet. Socrates grows about fourteen inches high, and promises to be a very useful addition to the already considerable list of dainty and fragrant varieties of Narcissus poeticus.



NARCISSUS SOCRATES.
A fine poeticus variety; A.M., R.H.S., April 25, 1911.

Exacum macranthum.—In the intense bluish-purple of its blossoms this Gentianwort stands out markedly from most other flowering plants at this season, while an additional feature is furnished by the golden anthers towards the centre of the flower. Of late years Messrs. J. Veitch and Sons have shown us that it is not nearly so difficult of cultivation as was at one time considered to be the case. A native of Ceylon, it used to be regarded as a stove plant, but coming from mountainous regions it may with advantage be grown much cooler, in fact, Messrs. J. Veitch and Sons look upon it as a subject for the warm greenhouse only. Treated in this way it keeps quite free from thrips, which often play havoc with it in a warmer structure. A mixture of loam, peat, leaf-mould, and sand will suit it well. —W. T.

PROPAGATION OF ROSES BY GRAFTING.

The increase of roses by budding in the summer and cuttings during autumn having been treated upon, a few notes upon grafting through the winter may prove useful. Although it may appear a little early to deal with the matter, the first stages must be entered upon now.

Stocks resulting from cuttings inserted last autumn must be lifted and potted at once, or we shall not have them moving sufficiently for the first batch of grafting. Various stocks can be used, and, although the Manetti is not so popular now, because of its alleged coarseness, this stock is by no means so rampant when its roots are confined to pots, and it still makes a most serviceable one for all but a few of the delicate teas and noisettes. Cutting briars are a little better, and are suited to all classes or sections. Then there is the seedling briar; and I have little hesitation in writing that three times as many of these are used annually as in the case of all other stocks put together. First of all, they are much cheaper, the crown is minus any semblance of pith, the scion can be placed actually upon the roots, and no rose dislikes it.

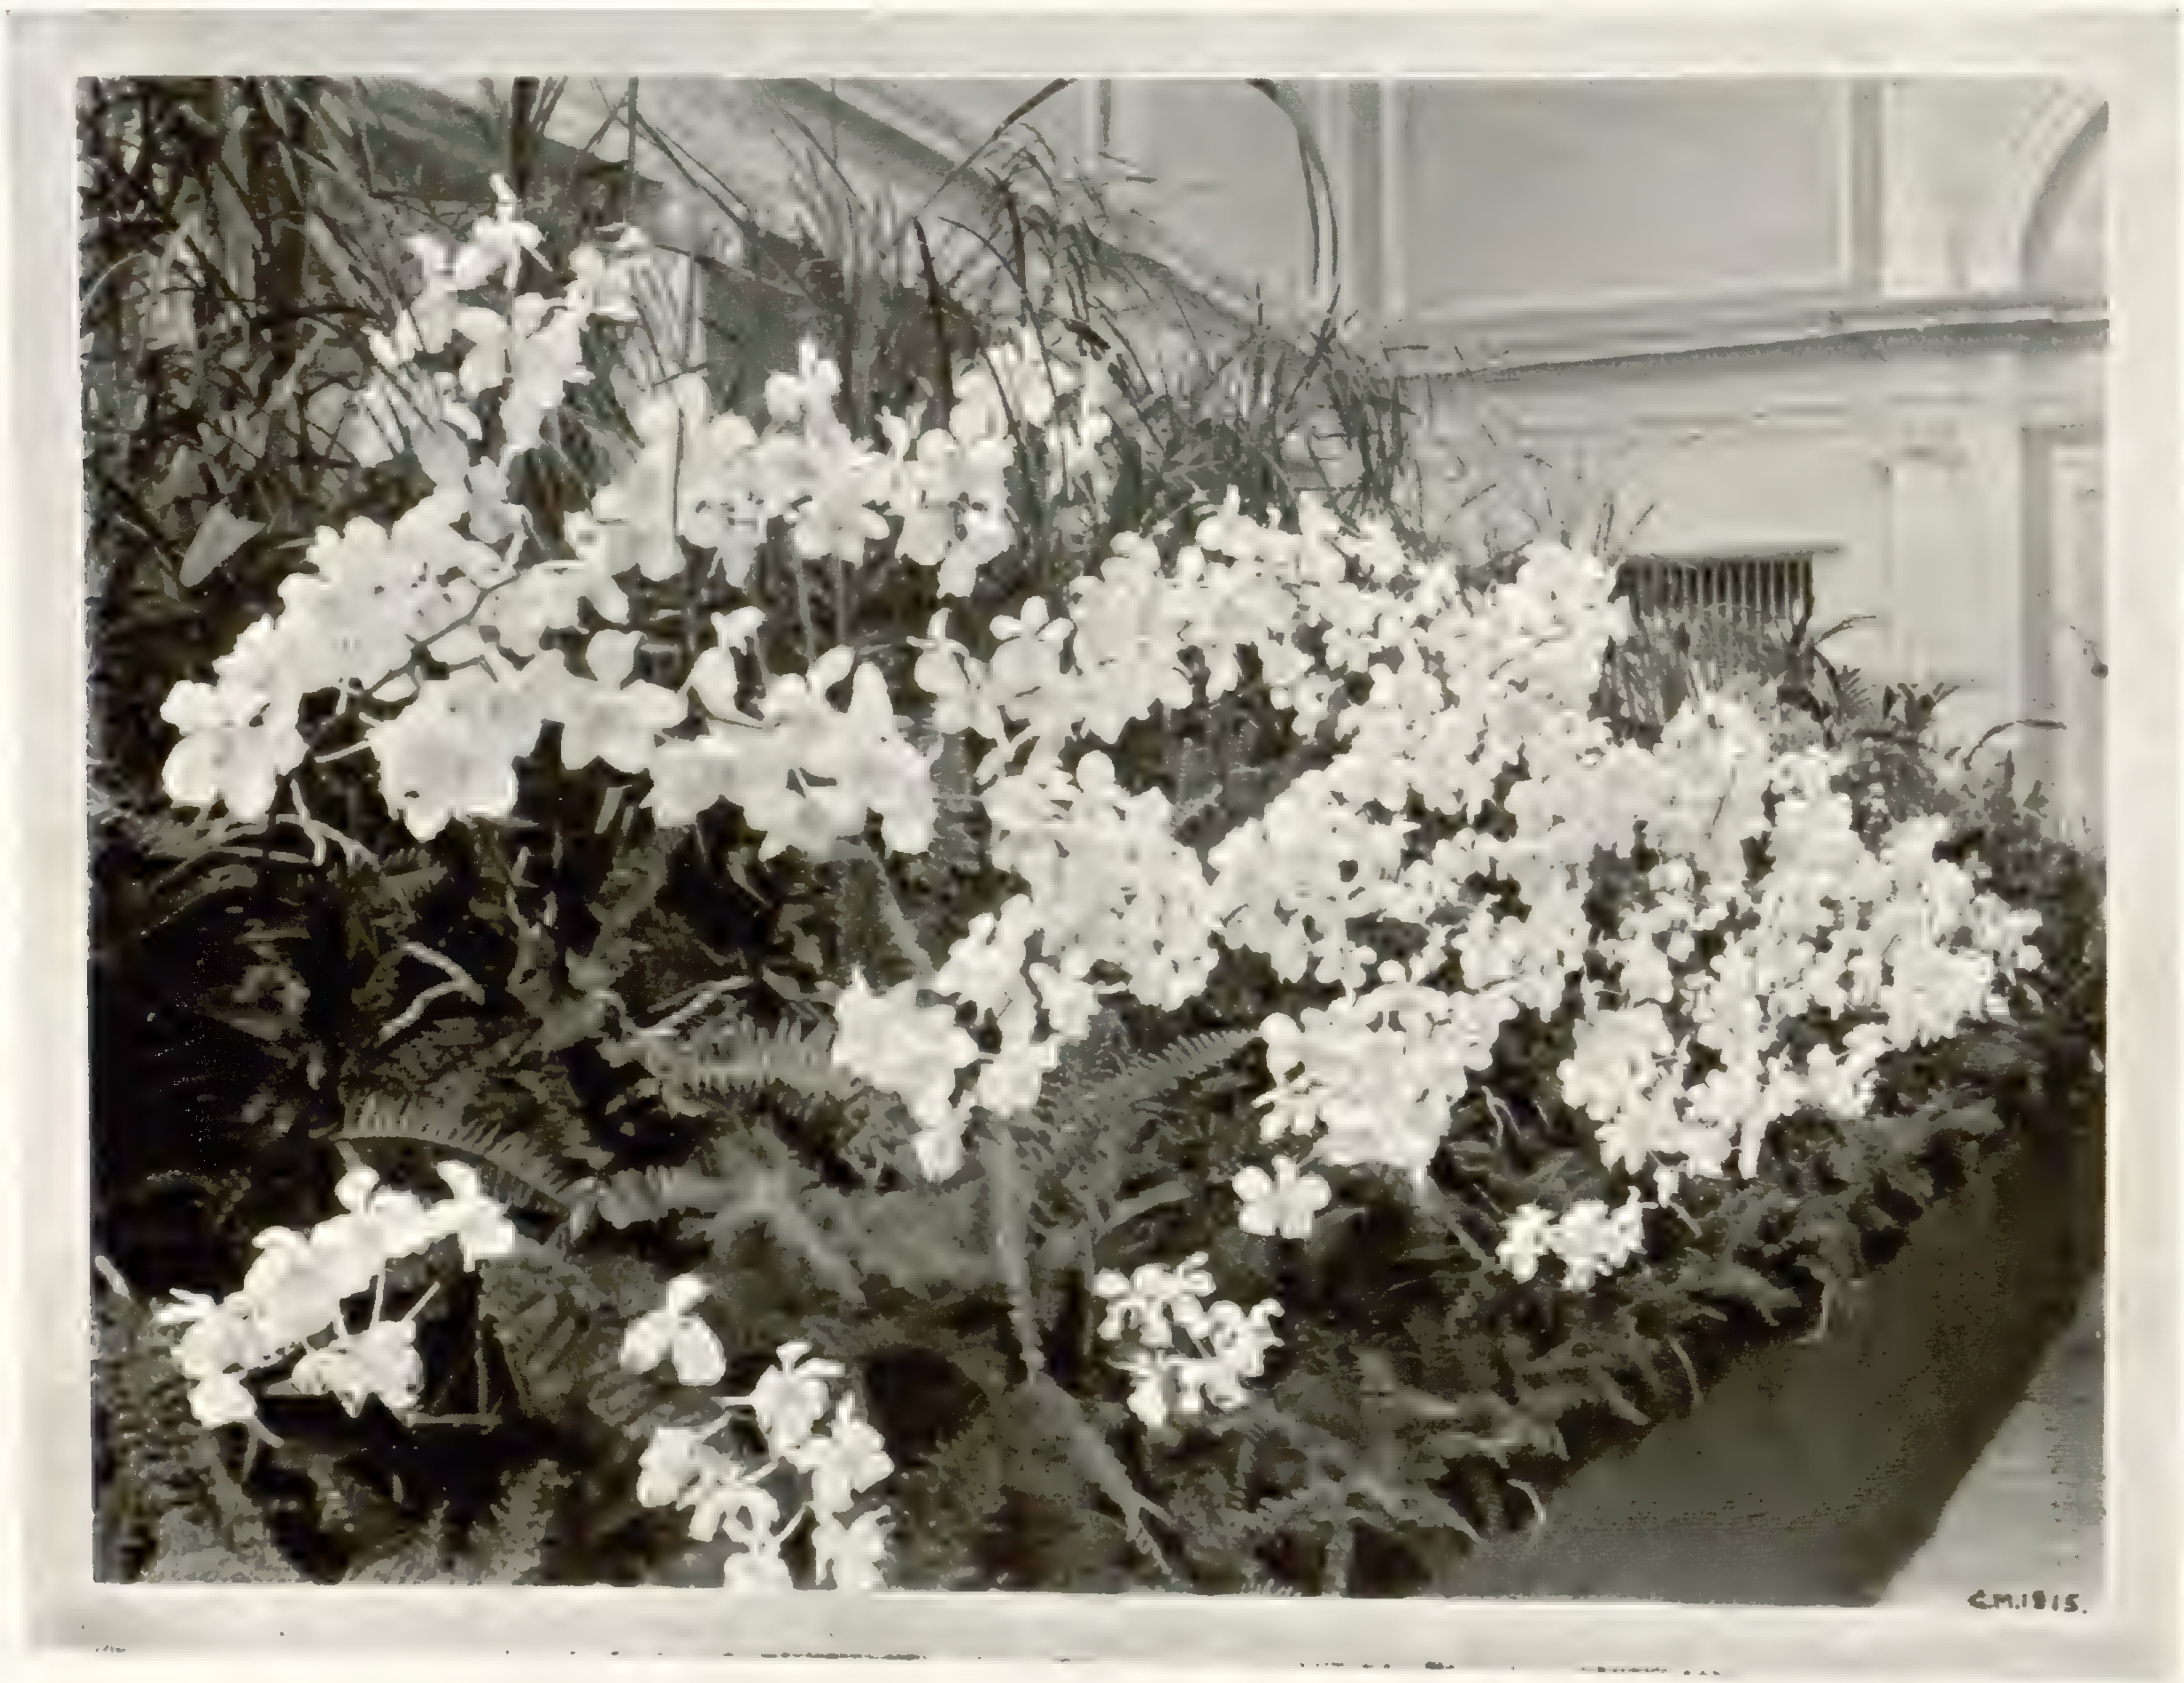
Use a compost of yellow loam with only just a little sand to keep it open. Leaf-soil and manures of all descriptions must be avoided, because they have a great tendency to produce fungus when in the close atmosphere of the propagating case. In our own case we use tiles, with a few washed ashes or fresh sand to stand the pots on.

When the stocks are potted, they should be plunged into some frame or pit, deep enough to cover the portion the rose graft is to occupy. Give a thorough watering, and let them be exposed to all except very bad weather. Here they will remain until batches are wanted for working. The first of these should be brought into a warmer house about a fortnight before they are to be grafted. I am aware that many advocate the graft and stock being in the same position, but my own experience is in favour of a little advance in the case of the stock, as the graft needs some support immediately the sap remaining in it becomes active. Future batches of stocks are introduced to a spell of warmth as needed, for I do not like them too forward. In spring, however, when using half-ripened wood, the stock may be a little more active, so as to be more in keeping with the condition of the green graft.

The propagating case should be perfectly clean. In fact, pots and all surroundings of the plants must be exempt from any suspicion of mustiness. Place the case so that a regular bottom-heat can be secured. Pipes enclosed beneath it are very good; but at the same time one should be able to get a drier atmosphere when needed. Much of this can be done with only one pipe, which I would not have inside the case, because we can regulate the latter by a little exposure so long as the outer atmosphere is in a fit condition. The glass over the case should tilt at a rather acute angle, so that the condensed moisture may not fall upon the grafts. There would appear to be something deadly to the young plants in the moisture on the glass. We have a small strip of wood for the bottom of the glass to rest upon, and this is so arranged that the drip runs out of the case. The top of the glass squares may rest upon anything most convenient, but I prefer a span-roofed case, the centre of which may be anything from six inches to a foot wide. This width will be found very convenient as a shelf to stand the young plants upon for a time when removing a few as they progress, and need a rather different atmosphere than would be suitable for the remainder; because all will not come on alike.

There are several forms of grafting. The two most generally used I will endeavour to describe. In the first we cut off the stock as closely to the root as possible, still allowing room for the graft to be fixed. This naturally depends upon the size of the scion used, which, again, depends upon the variety. If the graft is much smaller than the stock, the graft is cut wedged-shape and slipped into a corresponding cut in the stock. This method is more used now than a few years back, and is almost the only one among French and German growers. It makes a good union, and I do not think it quite so liable to break out in future handling as the older plan known as side or whip grafting. This last is simply the old form used in other subjects, and consists of a slanting cut upon the graft, with one of corresponding length on the side of the scion. It is certainly better in this form if the stock is not much larger than the scion.

One drawback to cutting brier stocks is their tendency to pith or soft centre. In this case, it is well to cut right through and fix the graft as if it was a continuation of the stock; choosing, of course, both of the same size. A sounder or less pithy stock may be used for side or cleft grafting. It is here, as I previously hinted, the value of firmness throughout, found in the seedling brier, is so appreciated.



FINELY-FLOWERED SPECIMENS OF VANDA CÆRULEA.

As exhibited by the Duke of Marlborough, Blenheim Palace, Woodstock (gardener, Mr. G. Hunter), at a recent meeting of the Royal Horticultural Society, when the award of a silver-gilt Flora Medal was made. Tastefully associated with elegant ferns, the soft blue flowers produced a delightful effect.

Make all firm with raffia and do not go to the quite unnecessary labour of waxing around the graft. It is not needed if the plants are placed in a case and treated as I will show. I have sometimes thought they do better without wax than with, believing the callus forms much quicker when more exposed to the genial temperature of the case.

Always make the top cut of the stock a trifle on the slant, and never place the graft upon the lower side of this. The object is to prevent moisture penetrating between graft and stock, which is very harmful. For this reason, the plants should not be watered overhead, but any necessary water must be applied to the soil carefully. Not much of this should be needed if the soil in the pots was a little more than moist and the bottom of the case not too dry to begin with.

Keep them quite close at first, and also dark until the callus forms. At no time should a bright light or sun come upon them until some progress is made. We like to remove the shading at night, and let a little subdued light reach them after callus has progressed. At any time when condensed moisture appears upon the glass it should be wiped off at once. As the grafts progress air admitted from the house itself in the early morning for a few minutes will do good. Some growers do not pay much attention to drying the glass with a cloth, but simply turn the glass over and allow the moisture to evaporate.

As the plants progress a little air may be allowed, and this is most readily done by leaving a small space between the squares of glass, more or less, as the plants are able to bear it. Even after the most forward plants have been taken from the case they must be carefully shaded from sun. At this period frequent overhead sprinklings will be beneficial; for now there will be no possibility of moisture penetrating between the stock and scion, as these have completely joined and no cavity remains.

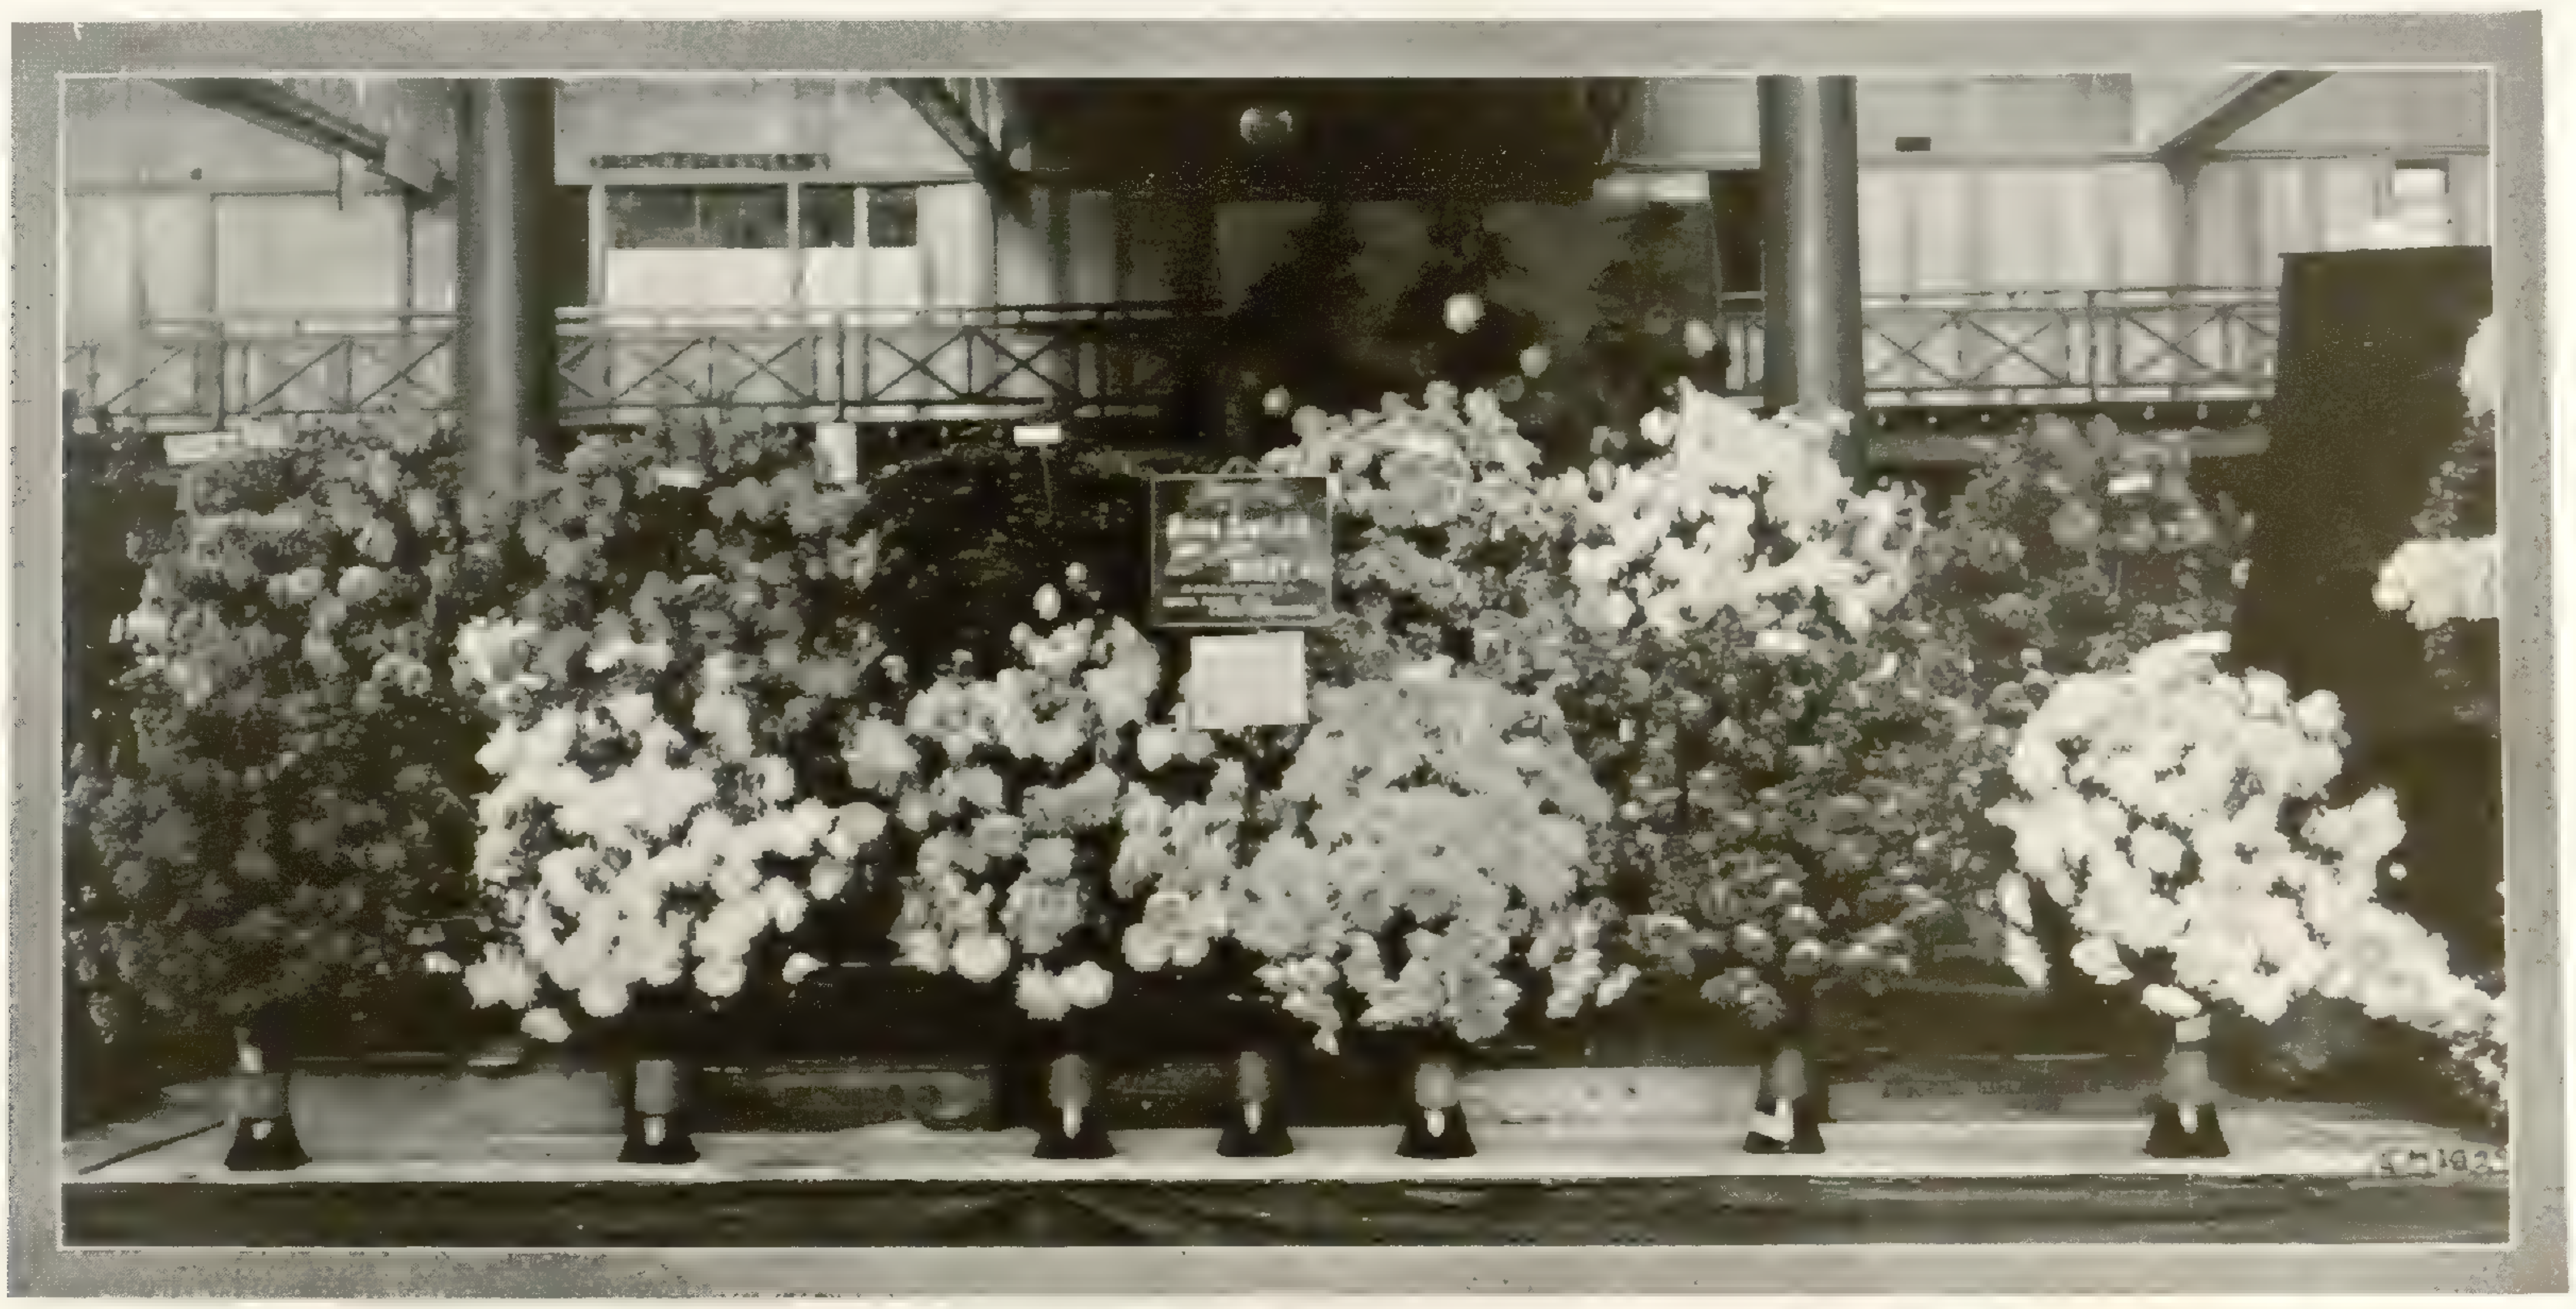
The after-treatment of the tiny plants depends upon the variety and also the purpose they are required for. They are potted on as growth demands and treated in the ordinary way. As one batch comes out of part of the case it may be occupied with the second lot of grafted stocks, and so on in rotation.

As I previously remarked one is not likely to get a batch of any one variety to come out all together. The plants should be selected, and the rest set up closer, so that they can still have the benefit of more or less close conditions. ROSARIAN.

AN EFFECTIVE EXHIBIT OF CHRYSANTHEMUMS.

There are two essentials to success in the exhibition of early-flowering chrysanthemums, as in the case of other flowers, one being the production of blooms of high quality, and the other the arrangement of the collections in such manner as to favourably impress the judges. The necessity of staging blooms in a high state of development is generally recognised, and cultivators usually make strenuous endeavours to obtain blooms that evince high-class cultural skill. But with regard to staging there does not appear to be a very general agreement as to the method of arrangement by which the best effect can be produced. Hence we see at exhibitions collections differing appreciably in style, and also in the manner in which the several styles are carried out. In the case of the flowers with which we are now immediately concerned we see, on the one hand, vases filled with blooms that have been grown under a system involving severe disbudding and high feeding, and on the other, collections that consist of flowers that have been naturally grown. In some cases the vases are so tightly packed with blooms as to produce a heavy effect, while in others they are so few as to present an ineffective appearance. We have, indeed, ample evidence each season that in the presentation of the early-flowering chrysanthemums to public notice a middle course is in every way the best for the display of their distinctive charms. There is no occasion in the cultivation of this section to endeavour to obtain, for example, blooms of Madame Marie Masse and its sports of the dimensions of one of the largest of the Japanese varieties, nor, indeed, is it desirable. The proper course is to give the plants the advantage of a moderately rich soil, and to remove sufficient buds on each branch to enable those remaining to attain their full development. With sprays of this kind far more effective and tasteful arrangements can be formed than is possible with sprays carrying large single blooms, or with those bearing a number of blooms only partly developed.

One of the most satisfactory collections of early-flowering chrysanthemums that we have met with at the exhibitions was that with which Mr. John Smellie, of Busby, obtained premier honours in the class for eighteen vases at the recent exhibition of the Royal Caledonian Horticultural Society at Edinburgh. The flowers were shown in vases that had a diameter of six inches, and the exhibitors were allowed full discretion as to the number of sprays used in filling the vases. Therefore, no restriction was placed upon the exhibitors in the exercise of their taste, and the judges were saved the trouble of counting the stems. As so frequently happens when exhibitors are allowed to use any number they please, there was some overcrowding in the several collections, and Mr. Smellie was not able to wholly avoid such mistake, but the overcrowding was much less than is suggested in the accompanying illustration. The sprays in the centre of the vase were cut with sufficient length of stem to stand about two feet above the top of the vase, and enough were used to form a rather loosely-arranged pyramidal bouquet, with a diameter at the base of about eighteen inches. The set of eighteen formed a rich display of colour, and were highly effective, although probably less so than would have been the case had they been arranged in three, instead of two tiers. This, however, was a small point, and the slight decrease in effectiveness was more than counterbalanced by the vases being so arranged as to be equally attractive on either side of the table. The collection, if not perfect in every particular, was immensely attractive, and afforded a valuable object-lesson in the arrangement of early-flowering chrysanthemums at exhibitions.



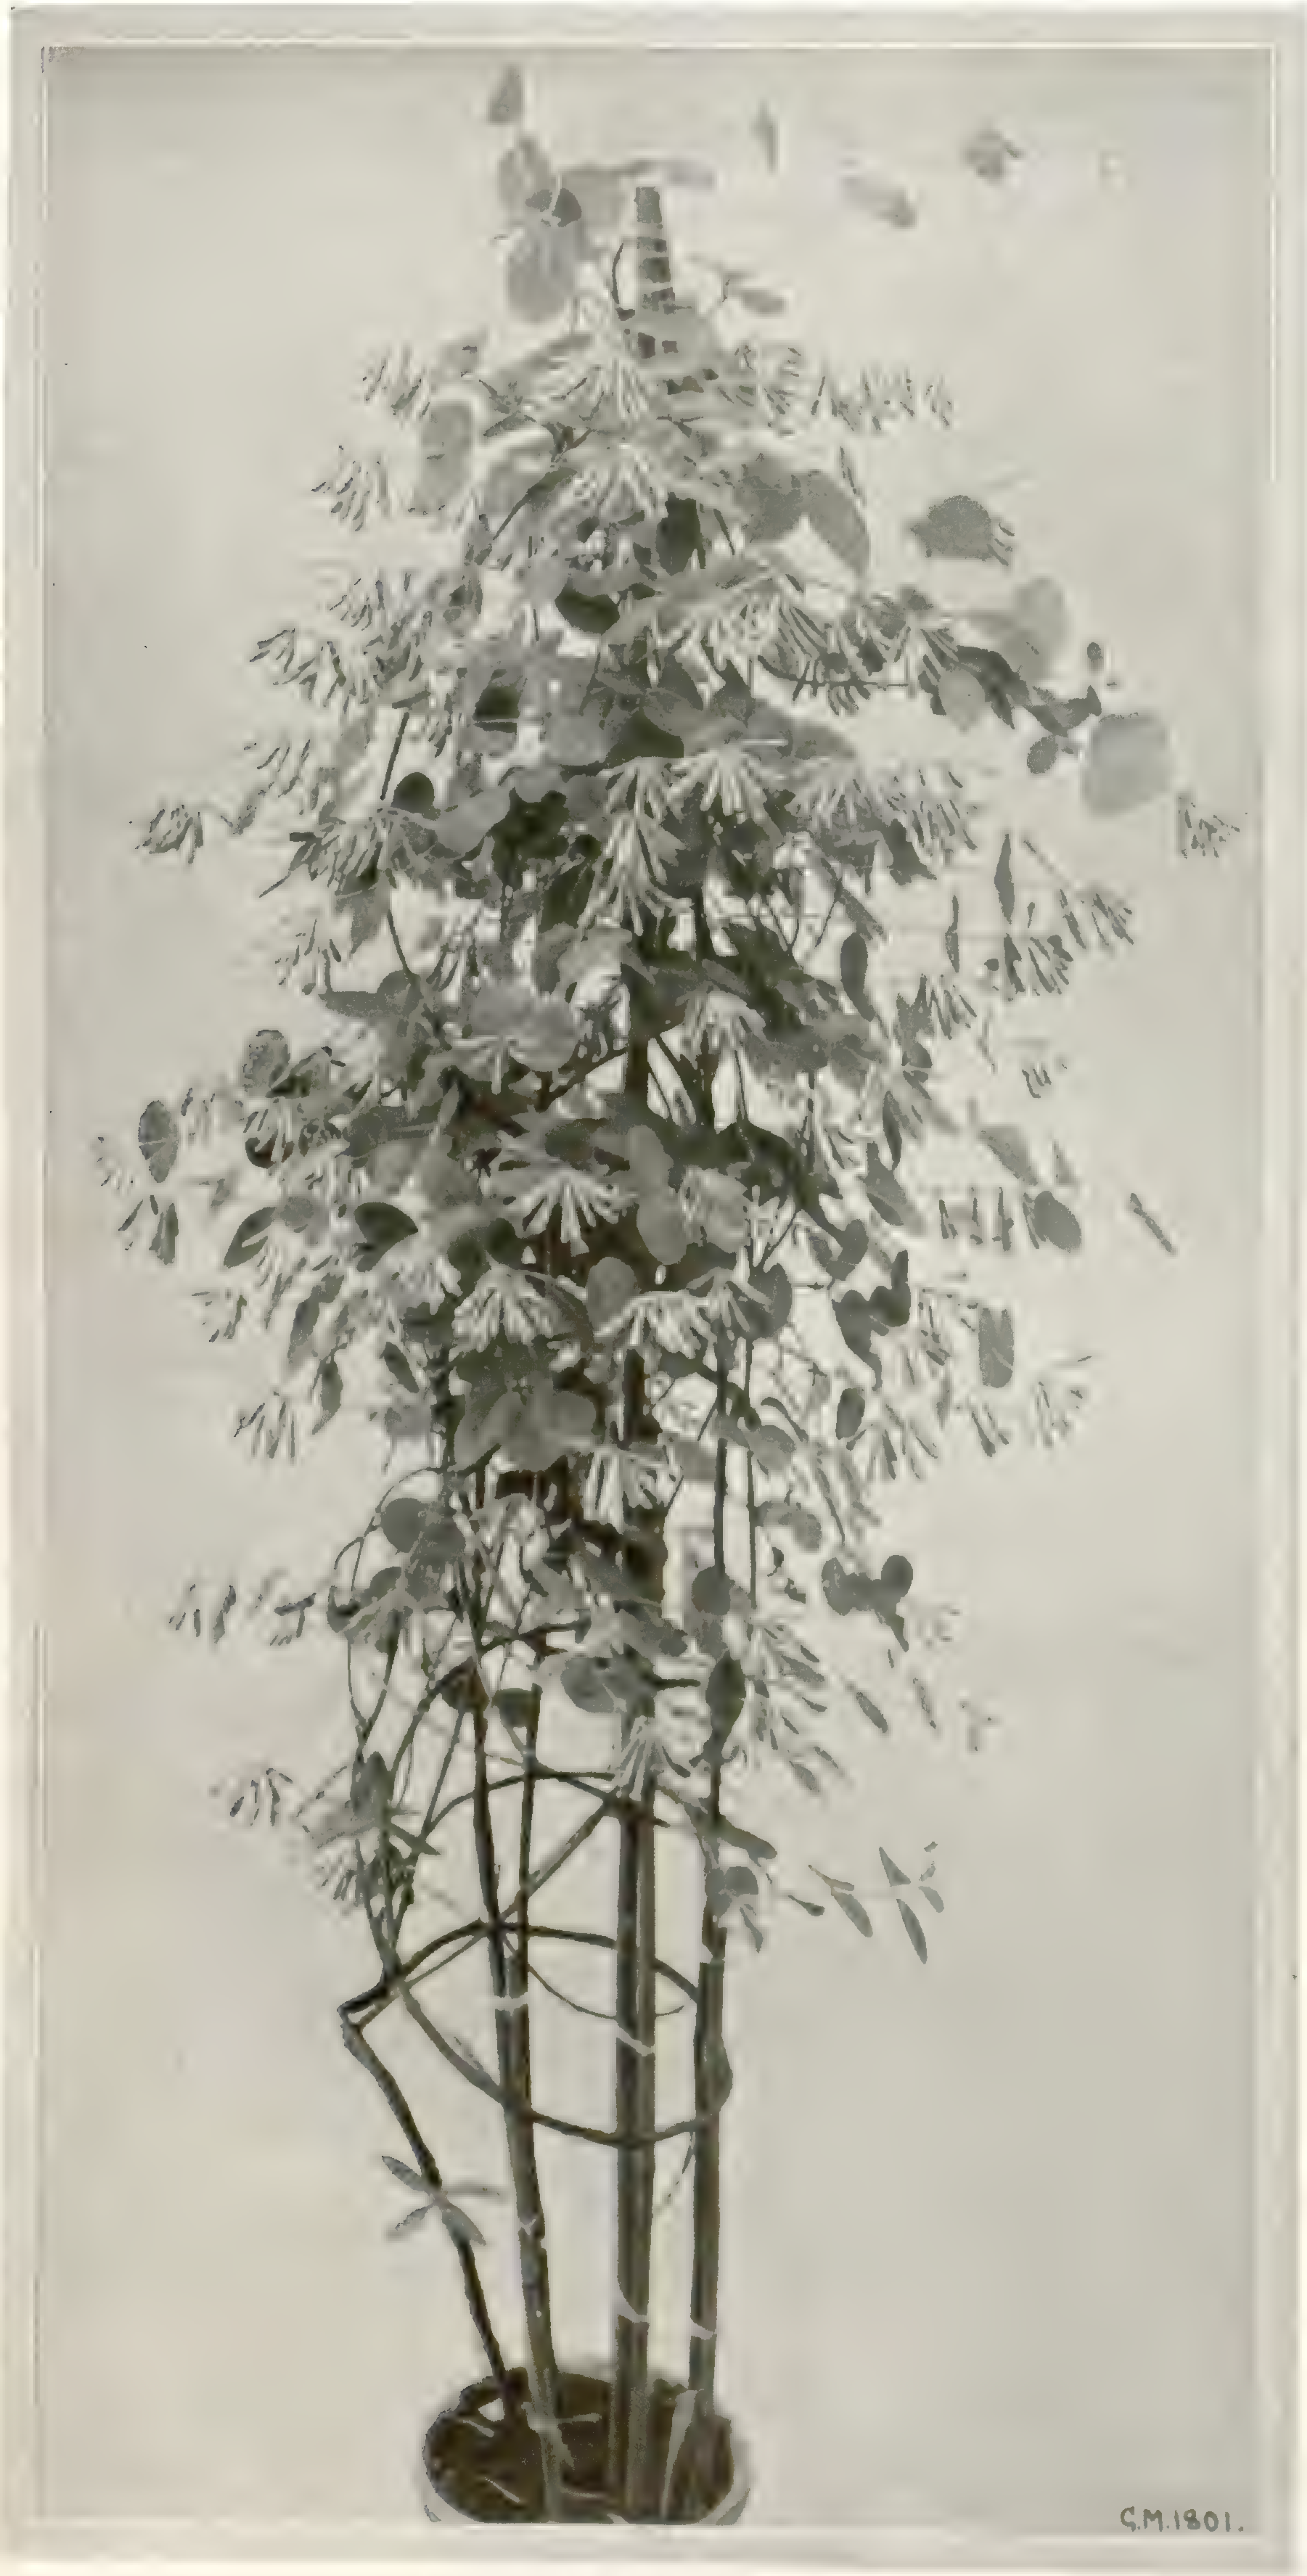
AN EFFECTIVE ARRANGEMENT OF EARLY-FLOWERING CHRYSANTHEMUMS.

For which Mr. J. Smellie was awarded the First Prize in the class for eighteen vases at the Edinburgh Flower Show.

Tomatoes. — These should now be moved inside and placed in their winter quarters, and if a house can be afforded it is a good plan to train them up the roof, but not nearer than eighteen inches to the glass. They may also be trained to stout stakes in a large house, on the stage, where they can receive full light. As soon as fruits have set give liquid manure or a little fertiliser, but upon no account overwater. — W. A. Cook.

LONICERA SEMPERVIRENS.

What a great pity it is that this beautiful climbing plant is not hardy in all parts of the country. It has so many good qualities worth a little care, even where the local conditions are against its culture out of doors. About a hundred years ago this species was regarded as "a good climber for the conservatory, and its beauty renders it worthy of such a situation," and the remark is equally true to-day. Except in the sunny south and in many parts of the Emerald Isle, where I have seen it growing in great beauty against the end walls or sides of plant houses, the Trumpet Honeysuckle is best considered as a conservatory or greenhouse climber. In the usual course of things one expects a climber to climb, and to be planted against a wall or where it can be trained up a pillar or under a rafter, and we only look with toleration upon climbing plants grown in pots and trained around stakes. And yet such pot-grown specimens are not to be despised, especially when they are so beautiful as the one here illustrated. In addition to the grace and beauty of Lonicera sempervirens so grown, such a method of culture permits the removal of the plant or plants out of doors during the summer and early autumn; indeed, it may very well go outside, in a sunny sheltered spot, as soon as it be finished flowering in May or June, and so make room for other things. Any way, a plant in a ten-inch pot, 5ft. or 6ft. high, and carrying a profusion of flowers, as shown, is beautiful. This plant was one of many equally beautiful seen at Messrs. William Paul and Son's nurseries, Waltham Cross, at the end of May last.



LONICERA SEMPERVIRENS.
An evergreen greenhouse climber, with clusters of scarlet and yellow flowers.

that it merits attention from all who love climbers; evergreen, free-flowering where it thrives, and producing clusters of scarlet blooms, each of tubular shape, and with a yellow interior, Lonicera sempervirens is

CRAB APPLES.

Crab-apple trees form a very effective feature in a garden, and combine the useful with the ornamental. In spring the flowers are charming, and in the autumn the highly-coloured scarlet-yellow fruits are very attractive. The fruits are useful when ripe for making a delicious jelly. But it is on account of their highly decorative qualities in the flower garden and pleasure-ground that I wish to draw the attention of readers of the GARDENERS' MAGAZINE to them in this note. In the beautiful gardens of Arcadia, the residence of Mr. G. H. Rolls, J.P., near Bournemouth, the variety John Downie does remarkably well in the shrubberies and other portions. The trees are objects of beauty which attract the eye from a considerable distance. The fruits are medium in size, conical in shape, borne in clusters in profusion, and are very richly-coloured. The Dartmouth variety has larger fruits of a rich crimson colour. Prolific is also a large-fruited, highly-coloured sort, and the Siberian Cherry has small fruits, rather yellow, but beautifully streaked with red.

In positions where the whole of the tree can be seen quite plainly pyramids are the best to grow, as all the varieties seem to be well adapted to this form. But in some shrubberies standards are the most effective. Where the soil is naturally good manures must not be added, as it is undesirable that a very strong growth be encouraged. In poor soils some good loam should be used at planting time to give the trees a start as it were, and afterwards, to maintain a satisfactory growth, surface mulchings may be relied upon. As little pruning as possible must be done.

GEO. GARNER.

Plagianthus Lyalli.—Among the subjects noted at one of the July meetings of the Royal Horticultural Society was this New Zealand member of the Mallow family. It was on that occasion given an Award of Merit. Introduced many years ago, this plagianthus was at first looked upon as tender, but now, at least in the southern counties of England, it has proved to be hardy. It forms a good-sized shrub of a somewhat loose habit of growth, whose branches are clothed with rugose leaves. The flowers, which depend from the axils of the leaves, and are supported by rather long pedicils, are individually about an inch across, pure white in colour, with yellowish anthers. Flowering as it does about the middle of July, it is of additional value.—W. T.

NOTES FROM HERE AND THERE.

The knowledge of the daily Press on matters of a rural character is simply marvellous, and whether the vein is optimistic or pessimistic, there is something about the way in which the information is given that is equally impressive. For instance, I remember reading some months ago an alarming article in an influential morning paper dealing with a new disease amongst bees, which, according to the paper, threatened to wipe these useful little creatures off the face of the earth. The other day in the same paper appeared another article which described the honey harvest of this season as the best on record, and never a word appeared about the disease. I cannot say anything as to the true state of affairs in respect of the latter, but I do know that bee-keepers are happy in their harvest, for never have the hives given a bigger supply or better honey. This condition of things is very gratifying, for the good honey harvest will have the effect of giving an impetus to bee-keeping, and be a means of inducing cottagers and small holders to take it up.

* * *

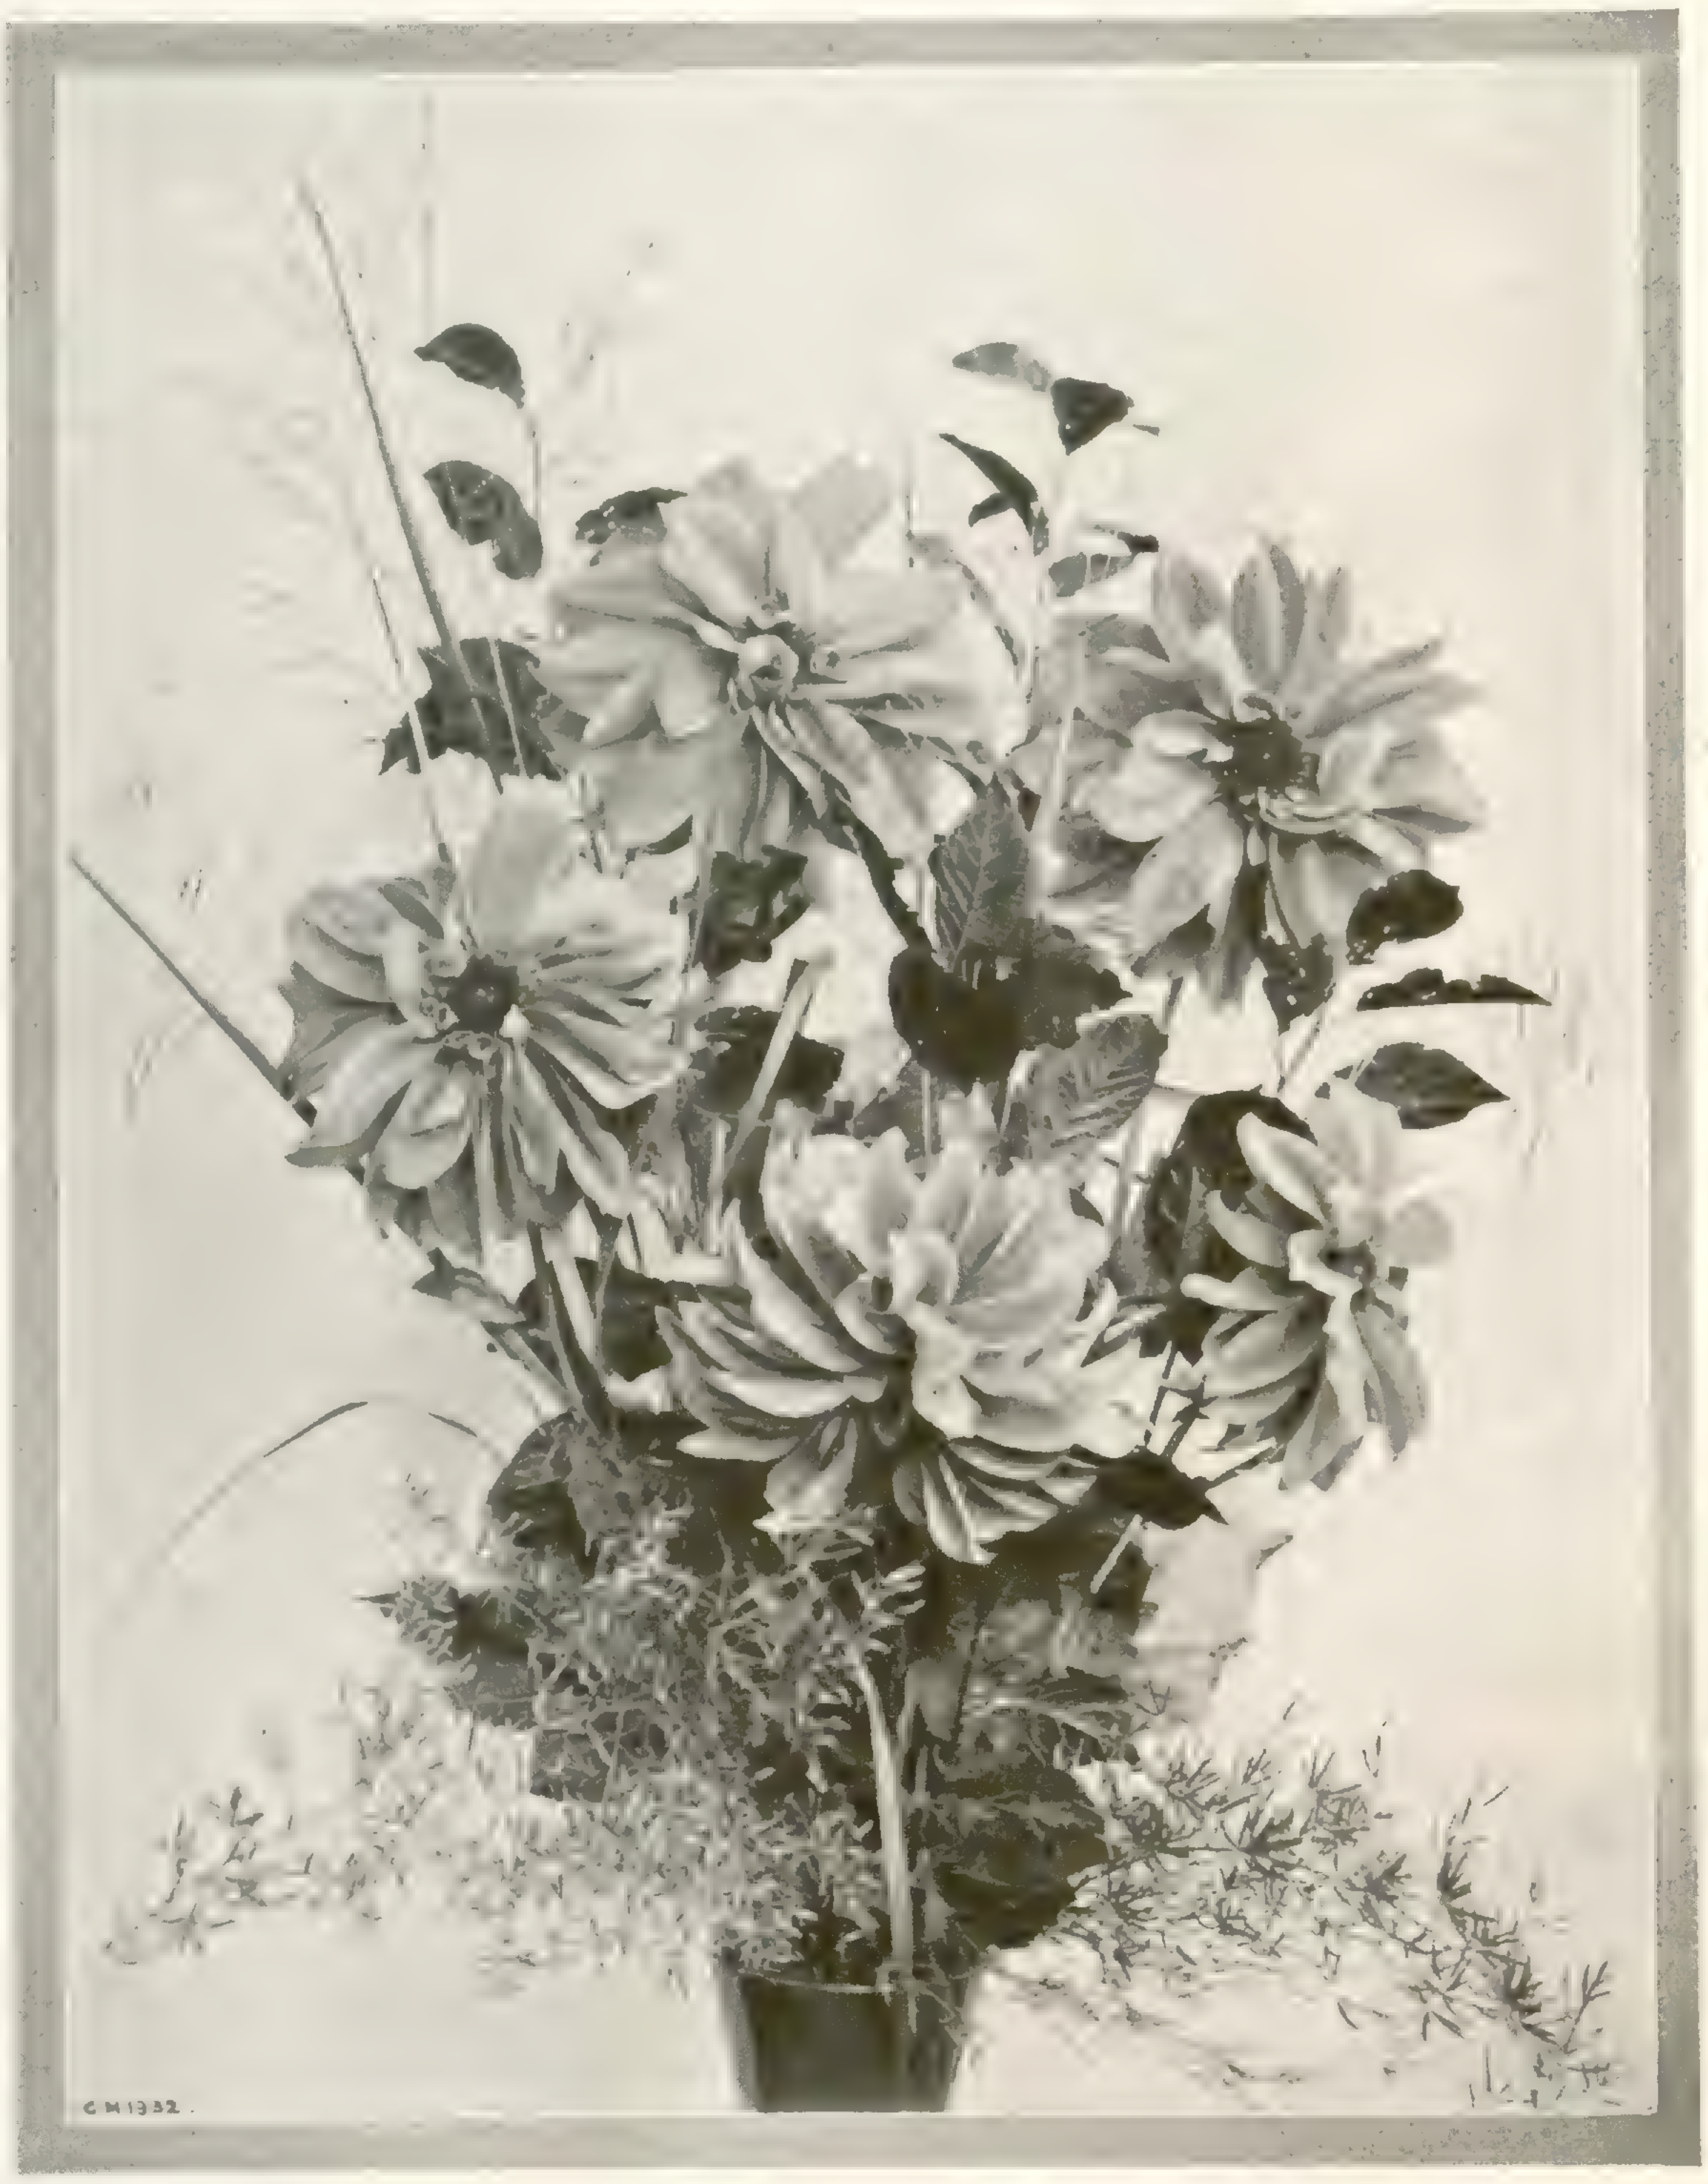
As a rule, we associate blackberry picking with the latter half of September, but this year the harvest of the hedgerows, like that of the fields, is early, and before August was out splendid blackberries were offered for sale in fruiterers' shops. In its way, too, this blackberry harvest is an important one, and by law of custom it belongs to the people. I happen to know something of a blackberrying district, and day by day I see women and children starting out in the morning with baskets and returning with them full. It cannot be said that farmers favour blackberry pickers, for reasons that are obvious, and notice-boards appear warning would-be trespassers of the fate that is in store for them if they enter certain fields. It is one thing to warn, however, but it is another to abolish a privilege which people have enjoyed for generations, and it is an easy matter not to see a notice-board if you don't wish to. Perhaps this explains the reason why warnings and notice-boards do not deter blackberry pickers, for tons of fruit are put into the market during the season, and the picking of it means boots and shoes for the winter in many a labourer's family.

* * *

Away down in the West Country there is a mellowness of harvest stealing over the orchards where the sun has painted rosy tints on the cheeks of apples, many of which, however, are deceptive, for, though inviting to look at, even the most hardened schoolboy would refuse them after the first bite. In short, it is the cider apples I refer to, and this year the harvest of the same is looked forward to with more than usual interest, because hogsheads are empty, and there is a scarcity of cider in the land. This to some extent is due to the consumption this thirsty season being greater than usual in the West Country, but there are also signs which indicate that the public taste for good cider is on the increase outside the counties where it has for generations been a household beverage. At any rate, cider has sold well this year, there is not much left, the somewhat decrepit-looking orchards on many farms have yielded useful profits, and it is anticipated that the sun which has painted the cheeks of the apples has also added to their composition those qualities which are essential for making good cider. H.

A HANDSOME VASE OF DAHLIAS.

Well-grown dahlia blooms, if borne on long stems, are particularly fine when carefully arranged in large vases with suitable foliage. To the florist who can only see beauty in a flower when it just fills a circle the newer pæony-flowered and giant decorative dahlias are beneath contempt, and we can enter into their feelings. But it must not be forgotten that crowds of flower lovers show a decided preference for unordered elegance in blooms, as against the primness and regularity of form so greatly admired and worked for by the florist. This being so, it is useless to shut one's eyes to the merits which, say, a pæony-flowered dahlia possesses, and which render it attractive to so many people. As has been shown in these pages on many occasions, pæony-flowered dahlias have a distinct value for large beds in public parks and gardens, and in the pleasure grounds of many private establishments. Even when considered as cut flowers for home use, or for decorative arrangements at exhibitions, these same varieties have many good qualities. They would look ridiculous on the dinner table except at some big public function, but for the sideboard, the hall table, a corner in the drawing-room, or a recess on the staircase, they may be used with advantage, and not many flowers will be needed to make up a bold and pleasing design.



A VASE OF PÆONY-FLOWERED DAHLIA SALOME.
One vase of a first prize set of six, staged at the National Dahlia Society's Show by Mr. Chas. Turner, Slough.

At the recent exhibition of the National Dahlia Society Mr. Charles Turner, Slough, won first prize for six vases of pæony-flowered dahlias, and every vase was a delight. With the flowers were associated a few grasses, some long growths of Prunus Pissardi, and some sprays of Asparagus Sprengeri. One vase attracted very general attention and admiration, and this is depicted in the present issue. The variety used was Salome, the flowers of wonderful size and brilliance, the colour being golden-orange shaded with buff; it has long, stout stems, and carries its big bright flowers erect without any assistance from wire or stick. The length and stiffness of the flower stems also add much to the value of the variety in the garden.

Pot Strawberries.—These have now well filled the pots with roots, and are in good condition to be supplied with liquid manure, which may now be given at every other watering, taking care the plants receive a real soaking, and on fine days syringing the foliage if dry weather continues, and damp the ashes about the pots with soot water.—W, A, Cook.

WORK FOR THE WEEK.

ORCHIDS.

CYPRIPEDIUM SEEDLINGS.—Most of the early sown cypripediums will now have formed a second leaf, and the young roots will be advancing from the base of the plants. With the cooler weather prevailing outside, and the small amount of artificial heat that is required at night, the conditions are most favourable for removing the young plants from their seed beds and transplanting them into pots. Where there are large quantities of seedlings the question of space becomes a serious question, and there is no alternative but to plant several of the seedlings together in the same pot; but where the question of room is not pressing, it is desirable the plants should be potted singly. There can be no doubt that the requirements of individual plants are more readily met when given a separate existence, as compared with the method of growing several together in store pots. There is always a great amount of difference between the vigour of plants, and to give the necessary conditions to the more robust generally ends in disaster to the weaker ones. Where there is lack of space little consideration is given to the weaker plants. the whole aim being to encourage those that are growing with the greatest vigour, so that the earliest possible flowering results may be obtained.

POTTING.—See that ample drainage is provided whichever method is adopted; the pots should be filled to about two-thirds their depth with clean drainage. The potting compost may be varied according to the section to which the seedlings belong. In the case of the winter-flowering, plain-leaved section, in all localities where the atmosphere is pure, I would advise the inclusion of some fibrous loam with the chopped peat and sphagnum (the latter being finely chopped to prevent its growing rapidly), with sufficient sand added to render the compost porous. Press the material moderately firm. The pots should be filled a few hours before they are wanted, and watered, as this will permit of drainage before the seedlings are pricked out. We find this a more suitable method than watering after they have been transplanted. For seedlings from C. bellatulum, C. niveum, C. Curtisi, C. Lawrenciarum, and others of the tesselated foliage section, and also for C. Rothschildianum seedlings, no loam should be included in the potting compost, and thus two portions of peat to one of finely chopped sphagnum moss is recommended.

SEEDLINGS OF ADVANCED GROWTH, in fact, all that are not likely to flower this season, may be repotted, if necessary, as there can be no doubt that the greatest advance of growth takes place in the autumn months. When repotting those that are likely to reach the flowering stage soon, see that the compost is of a lasting nature, and that reasonable root room is afforded. Water thoroughly as soon as potting is completed, and shade the plants from strong light for a time.—H. J. CHAPMAN, Oakwood Gardens

STOVE PLANTS.

BEGONIA GLOIRE DE LORRAINE and its varieties may now be allowed to develop their flower buds with a view to providing a display during the latter months of the season. The flowering house may be kept cooler and drier, a minimum temperature of 55 degrees being ample at this stage; the ventilators may be left open a little day and night, allowing a free and pleasant circulation of air without subjecting the plants to any cold draughts. Ample water may still be given to the roots, and fertilisers may be employed to prolong the flowering season. When arranging begonias in their flowering quarters some care should be taken to display every plant to the best possible advantage. A few light feathery plants of Arundinaria falcata will relieve the mass of colour. A few dwarf foliage plants, such as Rex begonias, Panicum variegatum, Fittonia argyroneura, with dwarf ferns, may be used as a groundwork, and also for the edging of the stages. Where these and similar plants are tastefully associated with the pink blooms of begonias the whole present a charming and pleasing effect which at this season cannot fail to be appreciated. Should thrips or greenfly be found at all troublesome, a thorough fumigation with nicotine compound will prove most beneficial.

PANCRATIUMS.—These useful bulbous plants will have completed their season of flowering, and they may be more fully exposed to the sunshine in a position near the glass, and, if convenient, raised above the stage so that their roots may be kept somewhat drier; this treatment will greatly benefit the ripening-up process. As soon as the foliage has decayed the pots may be stored in the intermediate stove in a dry position, and only sufficient water must be given to prevent the shrivelling of the bulbs.

GENERAL REMARKS.—Now that the season has so much advanced, preparations for providing the later display must be made by housing all the winter-flowering subjects. Poinsettias and euphorbias in particular must be transferred to their winter quarters, these are always most sensitive to a check from low temperature or cold draughts. Attention must be also given to artificial feeding, and extreme care must at all times be taken to avoid an excessive application of water to poinsettias and euphorbias during their flowering period, when growth of foliage is almost entirely suspended. Should any traces of insect pests be observed these must at any cost be eradicated before the plants commence to develop their blooms.—JOHN DONOGHUE, Bardon Hill Gardens.

FRUITS UNDER GLASS.

THE ORCHARD HOUSE.—A good supply of soil should now be made ready for potting any of the trees that may need it. This should be of a rich character, for when the roots are rigidly confined the food must be of the very best. A good and suitable mixture is the one recommended in the last calender for peach borders, i.e., good fibrous loam (not broken up too much) four parts, and one part of wood ashes and lime rubble and soot, and with a little bone-meal. Mix well, and, if desirable, let it be watered and then covered over to keep it in fit condition for use. Trees in large pots, and not intended to be shifted, should have as much of the surface soil removed as possible, and then be top-dressed; those in smaller pots should be given a small increase of rooting space, the soil being made firm between the old ball of soil and the pot. Over-potting is a mistake. Peaches, nectarines, apples, pears, plums, etc., can all be grown in pots successfully, and, if choosing a new stock from the nursery, choose trees of good shape and well furnished with fruit buds. After the potting and top-dressing give a thorough watering, syringe the trees each day, and they will soon become established. Let the pots stand on a good hard base in a somewhat sheltered corner, and, if possible, plunge the pots to save watering, as at this season the trees do best when not watered too freely.

TREES PLANTED OUT should also be dealt with, if any require root-pruning or thinning, as it is very necessary to keep plenty of space between orchard house trees, so that one tree does not deprive its neighbours of light and air. When trees become too large they should be turned out in the open, and smaller ones substituted. Trees grafted upon suitable stocks for early fruiting do not last long, as the stocks wear out quickly; for instance, pears on the quince stock do not last nearly so long as when on the pear stock; of course, they bear earlier, and that is the sole reason for utilising these early stocks. Good varieties for the orchard house are: Beurre Giffard, Clapp's Favourite, William's Bon Chretien, Souv. du Congrès, Louise Bonne of Jersey, Doyenne Boussoch, and Doyenne du Comice pears; Angelina Burdett, Denniston's Superb, Jefferson's, Reine Claude de Bavay, Transparent Gage, Oullin's Golden Gage, Golden Drop, and M'Laughlin Gage plums.

CUCUMBERS.—If these are not yet planted out, let them be dealt with at once. Train them carefully up to the wires by means of a neat stake. Give top-dressings in small quantities regularly, using sweet loam with a little spent mushroom bed manure or decomposed cow dung. The temperature should be kept at about 70 to 75 degrees by means of artificial heat.—W. A. COOK, Leonardslee Gardens.

THE FLOWER GARDEN.

FLOWER BEDS.—Specimen plants of heliotrope, ivy-leaf pelargoniums, fuchsias, etc., which have been growing in the beds during the summer months, should now be lifted and potted. The heliotropiums are the most tender, and should be taken in hand first. All subtropical plants must be removed and placed under cover where they will be out of danger from frosts. As the beds become vacant they should be refilled with wallflowers, bulbs, polyanthuses, or whatever subjects are to be used for the spring display. All beds that are in a poor condition must be enriched with a liberal supply of decayed manure, that is, when wallflowers or polyanthuses are to be grown, as both plants appreciate a rich soil, the polyanthuses preferring decayed cow manure. It is not advisable to add manure to the soil in beds intended for narcissi, but burnt garden refuse and well-rotted leaf-soil can be used instead. When lifting wallflowers one should always endeavour to retain a fair amount of soil about the roots, and if possible a dull day should be chosen for planting. It must be borne in mind that the less check the plants have the quicker they will re-establish themselves, and the loss of foliage will be small. Being such a hardy subject the wallflower is often roughly handled, and consequently does not become sufficiently rooted before the severe weather sets in. Firm planting is another point to remember. A little care and attention goes a long way towards the success of the spring display, and one is amply repaid for the extra time and trouble taken. Regarding bulbs, unless they are planted thickly, it is necessary to carpet the beds to cover the soil; plants suitable for the purpose are aubrietias, arabis, Viola gracilis, myosotis, the mossy saxifragas, and other plants of dwarf habit.

GLADIOLI.—When the foliage shows signs of ripening, the corms should be lifted, as it is not necessary to leave them in the ground until the foliage is absolutely decayed. The best plan is to tie them up in bundles and hang them up in an airy, frost-proof shed, carefully labelling the bundles to prevent confusion when they are being prepared for planting.

ANCHUSA ITALICA and its varieties may be readily propagated now, by cutting up the fleshy roots in exactly the same manner as seakale sets are prepared. These pieces of roots or sets should be dibbled into seed boxes which have been previously filled with sandy soil, and placed in a cold frame.

DELPHINIUMS.—Where it is considered necessary to lift and replant delphiniums the work should be accomplished without delay, so that the plants may become established before the severe weather sets in. As they will probably remain undisturbed for three or more seasons, it is important the ground should be thoroughly dug or trenched and enriched with well-decayed manure before replanting. Great care must be exercised if the roots are to be divided. or much damage will result. A fork thrust into the clump sideways will usually split the woody parts, and one can then pull the pieces apart by hand. Slugs eat the young growths underground during the winter months and early spring, therefore every precaution should be taken to prevent the ravages of these pests. There are several preparations on the market which may be used for the purpose.—E. C. POOLEY, Gnaton Gardens,

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

On Tuesday, September 26, the Royal Horticultural Hall was filled from end to end with exhibits of varied character and interest. The dahlias and orchids provided rare colour, and ornamental plants and gourds were not less attractive. Vegetables and fruits added their quota of beauty and usefulness, and hardy autumn flowers filled up all the rest of the space.

There was a vegetable show on this date, and the many classes provided were fairly well filled.

FLORAL COMMITTEE.

Across the end of the hall Messrs. Jas. Veitch and Sons, Chelsea, put up a magnificent exhibit of stove and greenhouse plants, one that was excellent both from a cultural and artistic point of view. The background was composed of very tall cocoses with big specimens of Dracæna Goldieana, D. Godseffiana, D. Sanderiana, Anthurium Veitchi, Cocoloba pubescens—with huge leaves, Heliconia illustris rubricaulis, Croton Thompsoni, C. Reidi, etc. In the foreground were splendid examples of nepenthes raised on tall asparagus-clad stands, and these commanded great admiration, especially such handsome kinds as N. Curtisi superba, N. Sir William Thiselton Dyer, N. Mastersiana, N. elegans, N. mixta, and N. Tiveyi. A bright central group of hybrid orchids, with small flanking groups of Lilium speciosum, and cannas and nerines, formed with baskets of choice Rex begonias, bertolonias, Dracæna deremensis Warnecki, crotons, ferns, and selaginellas, a fine frontage to a grand effort.

Michaelmas daisies were extensively shown by Messrs. Barr and Sons, Covent Garden, and their exhibit included Solidago Golden Wings, phloxes, the graceful Vitis Lowi, colchicums, Sternbergia lutea, tritomas, etc.

Mr. Lister, gardener to the Earl of Warwick, Easton Lodge, Dunmow, brought up some very beautiful water lilies of the Stellata section, and two of these named respectively, Listeri and Lord Brooke, were very beautiful; and each gained an A.M.; the latter has deep rosy-mauve orange-centred flowers, and the former is deep blue with a yellow centre. Nymphæa stellata rosea (A.M.) was well shown by Mr. J. Hudson, V.M.H., Gunnersbury House Gardens.

Messrs. Allwood Brothers, Haywards Heath, showed May Day, Mrs. C. F. Raphael, White Wonder, and other good perpetual carnations, including a pale yellow variety of French origin, named Le Jaune Reanente.

Nerine Veitchi (A.M.), a new species with quite large blush white flowers, was shown by Messrs. R. Veitch and Sons, Exeter, who also presented a beautiful new bigeneric hybrid between Cyrtanthus sanguinea and Vallota purpurea; it had semi-pendulous flowers of a pleasing soft orange colour. Nerine Bowdeni and Veronica Veitchi with deep blue flowers were also shown by the Exeter firm.

Messrs. Thos. S. Ware, Lim., Feltham, made a goodly display with pæony-flowered and cactus dahlias, many of their own raising. A very bold display of dahlias from Mr. M. V. Seale, Sevenoaks, was notable for its pretty frontage of small cactus and pompon cactus varieties arranged in baskets of a variety. A big and brilliant bank of great bunches of popular cactus, single, pæony-flowered, and decorative dahlias from Messrs. Carter Page and Co., London Wall, provided a magnificent blaze of colour. Mr. J. T. West, Brentwood, made a great show of dahlias, and put up his new Brentwood Yellow and new pæony-flowered varieties in fine form.

A group of verbenas, in pots, staged by Mr. E. Beckett, V.M.H., gardener to the Hon. Vicary Gibbs, Elstree, once more brought under notice the usefulness of these old florists' flowers. Mr. J. B. Riding, Chingford, again submitted an interesting collection of collarette dahlias. Messrs. Bakers, Wolverhampton, produced a fine blaze of colour with about fifty large bunches of big pæony-flowered dahlias, the colours ranging from white to deep crimson, and including some lovely pink, rose, and fawn shades.

Exquisitely beautiful was the wide run of splendid colchicums from Messrs. James Backhouse and Son, Lim., York. The flowers were grand in their simple loveliness, especially those of C. speciosum album. The typical C. speciosum, C. autumnale, C. a. floribunda, and Crocus speciosus were included in an exhibit that, among hardy flowers, had no equal in the hall. Michaelmas daisies were shown from Mr. H. J. Jones' nurseries, Lewisham, who staged the varieties in large graceful bunches, Ringdove, Mrs. Duncombe Mann, Grace, Grandis, Gaiety, and Perfection, were small-flowered sorts of special elegance and beauty.

Messrs. H. Cannell and Sons, Swanley, contributed a bank of dahlias, and gained an A.M., for a bright crimson-scarlet collarette variety named Hon. Vicary Gibbs. Messrs. J. Cheal and Sons, Crawley, were also extensive exhibitors of dahlias, and made a special feature of pompon-cactus varieties.

Autumn flowers were grouped in quantity by Messrs. William Cutbush and Son, Highgate, and in their display solidagos, Michaelmas daisies, Crinum Powelli alba, Colchicum Bornmulleri, C. speciosum, tritomas, and pentstemons were the leading subjects. Mr. James Box, Lindfield, filled a corner with a very bright group of Michaelmas daisies, Solidago Golden Wings, Artemisia lactiflora, and Helianthus sparsifolius; all good things.

Messrs. H. B. May and Sons Edmonton, once again contributed a large collection of choice ferns. Phloxes, elegant Michaelmas daisies, carnations, and early chrysanthemums, from Messrs. W. Wells and Co., Merstham, made a bright display.

Mr. G. Reuthe, Keston; Messrs. G. and A. Clark, Dover; and Mr. L. Russell, Richmond (clematis) were also exhibitors.

ORCHID COMMITTEE.

Among the orchids exhibited by Messrs. Sander and Sons, St. Albans, a few of the finer things were Brasso-cattleya Veitchi, Vanda Sanderiana, Cattleya Thayeriana, C. bellatula, C. Dowiana aurea, and Cypripedium insigne Sanderæ.

Oncidium varicosum Rogersi made a pretty background for the group of orchids submitted by Messrs. S. Low and Co., Enfield; here also were Cattleya Gaskelliana alba, C. Iris, Lælio-cattleya Luminosa, Odontioda Thwaitesi, and other good things.

Messrs. Charlesworth and Co., Haywards Heath, presented a few very fine orchids, notably Vanda Marguerite Maron, Cattleya Venus—a glorious variety. Oncidium Lanceanum, and Odontoglossum Harwoodi The Shrubbery var. (F.C.C.), a superb orchid, with yellow flowers, and deep red-brown markings; the three big blotches of velvety red-brown on the broad, rounded lip were wonderfully attractive.

Mr. G. M. Hale, gardener to S. Larkin, Esq., Haslemere, put up a small group of orchids, in which Cattleya Iris and Phalænopsis violacea were leading subjects. From Sir Trevor Lawrence's collection at Burford Lodge, Dorking, Mr. W. H. White brought up finely-grown specimens of Zygopetalum maxillare with about a dozen and a-half spikes (Cultural Commendation); Epidendrum floribundum, Epidendrum Lauchianum (A.M.), with two long pendulous spikes of small brown and green and yellow-green flowers.

Mr. Hopkins gardener to Francis Wellesley, Esq., Westfield, Woking, submitted Cattleya Mrs. Frederick Sassoon (aurea x Mantini nigrescens), which gained an A.M., and is a very hadsome purple and old gold-coloured variety; Cypripedium Dowleri, and Cattleya Gaskelliana Delight.

Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton, submitted a basket of flowering plants of the bright orange-coloured Habenaria militaris, and a Cultural Commendation was granted. From Messrs. Hassall and Co., Southgate, came some well-grown examples of Cattleya Minucia, C. Fabia, C. Nestor, C. Mantini nobilior, L.-c. Walter Gott, and other fine autumn-flowering subjects.

Cypripedium Wiertzianum, with four spikes, and a total of eight big flowers, was the chief attraction among the orchids staged by Mr. E. V. Low, Haywards Heath; C. Rossetti Westonbirt var., C. triumphans, and Cirrhopetalum ornatissimum were included in the exhibit. A plant of Odontoglossum Memoria Baron Schröder, the committee asked to see again, as the flowers were not yet fully open.

Mr. J. Day, gardener to H. S. Goodson, Esq., brought up Lælio-cattleya St. Gothard, and a few other good things.

FRUIT AND VEGETABLE COMMITTEE.

A vastly interesting and extensive exhibit of ornamental gourds from Mr. Thos. Stevenson, gardener to E. A. Mocatta, Esq., Woburn Place, Addlestone, was a distinct feature of the show. The display filled a space about 36ft. by 6ft., and there were about two tons of gourds, many of them two feet and upwards in diameter; while others were quite tiny, only an inch or so across. Some were so heavy, like the Giant Red Etampes, Giant Paris, Portuguese, Grey Boulogne, and other huge gourds, that they tipped the beam at from 50lb. to 89lb. each. In shape, too, there was a wonderful variety, some were round, others like the Snake Gourd, measured 5ft. in length; some were like Indian clubs, others resembled oranges, gooseberries, pears, dumb-bells, eggs, bottles, clubs, pipes, syphons, etc. In colour there was a range from white and pale-green to deep crimson, bright gold, and dark purple. The arrangement of the group was excellent, and we feel sure no such collection of ornamental gourds as this one of some seventy varieties has ever been placed before the public in this country. Our readers will remember that at Woburn Place a big pergola is annually devoted to these gourds.

Mr. James Whittle, gardener to Lieut.-Colonel A. C. Borton, Chevening, Hunton, Maidstone, put up an unusually fine exhibit of fruit, and tastefully disposed his splendid samples in flat, handled, and round baskets, and on dishes of various sizes. Apples, pears, plums, damsons, crabs, blackberries, nuts, and peaches were included. Among apples we noted superb fruits of Mère de Ménage, Warner's King, Newton Wonder, Wealthy, Belle Dubois, Gascoyne's Scarlet, Rival, Emperor Alexander, Lady Henniker, The Queen, Alfriston, Allington Pippin, Blenheim Pippin, Cox's Orange Pippin, King of the Pippins, Mabbot's Pearmain, and Ribston Pippin.

A large and particularly well displayed collection of vegetables from Messrs. Sutton and Sons, Reading, was a very attractive and interesting feature. The numerous kinds were arranged in three broad tiers, and every dish was of the finest quality. The staging was most tasteful. A few vegetables that commanded special attention were Michaelmas White broccoli and Autumn Mammoth cauliflowers; Satisfaction, Abundance, Perfection, and Eclipse tomatoes; A1., Sutton's Scarlet, Prizewinner, and Best of All runner beans; Ailsa Craig onions; Gladstone peas; Sutton's Black beet—very fine; Sutton's Heartwell lettuce; and radishes in great variety.

The large and well-arranged collection of vegetables contributed by Messrs. James Veitch and Sons, Chelsea, was bright with baskets of Invicta, Ham Green Favourite, The Hastings, Sunset, and Sunnybank tomatoes, Autumn Giant cauliflowers, Hackwood Park runner beans of great length and very

WORK FOR THE WEEK.

ORCHIDS.

CYPRIPEDIUM SEEDLINGS.—Most of the early sown cypripediums will now have formed a second leaf, and the young roots will be advancing from the base of the plants. With the cooler weather prevailing outside, and the small amount of artificial heat that is required at night, the conditions are most favourable for removing the young plants from their seed beds and transplanting them into pots. Where there are large quantities of seedlings the question of space becomes a serious question, and there is no alternative but to plant several of the seedlings together in the same pot; but where the question of room is not pressing, it is desirable the plants should be potted singly. There can be no doubt that the requirements of individual plants are more readily met when given a separate existence, as compared with the method of growing several together in store pots. There is always a great amount of difference between the vigour of plants, and to give the necessary conditions to the more robust generally ends in disaster to the weaker ones. Where there is lack of space little consideration is given to the weaker plants, the whole aim being to encourage those that are growing with the greatest vigour, so that the earliest possible flowering results may be obtained.

POTTING.—See that ample drainage is provided whichever method is adopted; the pots should be filled to about two-thirds their depth with clean drainage. The potting compost may be varied according to the section to which the seedlings belong. In the case of the winter-flowering, plain-leaved section, in all localities where the atmosphere is pure, I would advise the inclusion of some fibrous loam with the chopped peat and sphagnum (the latter being finely chopped to prevent its growing rapidly), with sufficient sand added to render the compost porous. Press the material moderately firm. The pots should be filled a few hours before they are wanted, and watered, as this will permit of drainage before the seedlings are pricked out. We find this a more suitable method than watering after they have been transplanted. For seedlings from C. bellatulum, C. niveum, C. Curtisi, C. Lawrenciarum, and others of the tesselated foliage section, and also for C. Rothschildianum seedlings, no loam should be included in the potting compost, and thus two portions of peat to one of finely chopped sphagnum moss is recommended.

SEEDLINGS OF ADVANCED GROWTH, in fact, all that are not likely to flower this season, may be repotted, if necessary, as there can be no doubt that the greatest advance of growth takes place in the autumn months. When repotting those that are likely to reach the flowering stage soon, see that the compost is of a lasting nature, and that reasonable root room is afforded. Water thoroughly as soon as potting is completed, and shade the plants from strong light for a time.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

BEGONIA GLOIRE DE LORRAINE and its varieties may now be allowed to develop their flower buds with a view to providing a display during the latter months of the season. The flowering house may be kept cooler and drier, a minimum temperature of 55 degrees being ample at this stage; the ventilators may be left open a little day and night, allowing a free and pleasant circulation of air without subjecting the plants to any cold draughts. Ample water may still be given to the roots, and fertilisers may be employed to prolong the flowering season. When arranging begonias in their flowering quarters some care should be taken to display every plant to the best possible advantage. A few light feathery plants of Arundinaria falcata will relieve the mass of colour. A few dwarf foliage plants, such as Rex begonias, Panicum variegatum, Fittonia argyroneura, with dwarf ferns, may be used as a groundwork, and also for the edging of the stages. Where these and similar plants are tastefully associated with the pink blooms of begonias the whole present a charming and pleasing effect which at this season cannot fail to be appreciated. Should thrips or greenfly be found at all troublesome, a thorough fumigation with nicotine compound will prove most beneficial.

PANCRATIUMS. — These useful bulbous plants will have completed their season of flowering, and they may be more fully exposed to the sunshine in a position near the glass, and, if convenient, raised above the stage so that their roots may be kept somewhat drier; this treatment will greatly benefit the ripening-up process. As soon as the foliage has decayed the pots may be stored in the intermediate stove in a dry position, and only sufficient water must be given to prevent the shrivelling of the bulbs.

GENERAL REMARKS.—Now that the season has so much advanced, preparations for providing the later display must be made by housing all the winter-flowering subjects. Poinsettias and euphorbias in particular must be transferred to their winter quarters, these are always most sensitive to a check from low temperature or cold draughts. Attention must be also given to artificial feeding, and extreme care must at all times be taken to avoid an excessive application of water to poinsettias and euphorbias during their flowering period, when growth of foliage is almost entirely suspended. Should any traces of insect pests be observed these must at any cost be eradicated before the plants commence to develop their blooms.—JOHN DONOGHUE, Bardon Hill Gardens.

FRUITS UNDER GLASS.

THE ORCHARD HOUSE.—A good supply of soil should now be made ready for potting any of the trees that may need it. This should be of a rich character, for when the roots are rigidly confined the food must be of the very best. A good and suitable mixture is the one recommended in the last calender for peach borders, i.e., good fibrous loam (not broken up too much) four parts, and one part of wood ashes and lime rubble and soot, and with a little bone-meal. Mix well, and, if desirable, let it be watered and then covered over to keep it in fit condition for use. Trees in large pots, and not intended to be shifted, should have as much of the surface soil removed as possible, and then be top-dressed; those in smaller pots should be given a small increase of rooting space, the soil being made firm between the old ball of soil and the pot. Over-potting is a mistake. Peaches, nectarines, apples, pears, plums, etc., can all be grown in pots successfully, and, if choosing a new stock from the nursery, choose trees of good shape and well furnished with fruit buds. After the potting and top-dressing give a thorough watering, syringe the trees each day, and they will soon become established. Let the pots stand on a good hard base in a somewhat sheltered corner, and, if possible, plunge the pots to save watering, as at this season the trees do best when not watered too freely.

TREES PLANTED OUT should also be dealt with, if any require root-pruning or thinning, as it is very necessary to keep plenty of space between orchard house trees, so that one tree does not deprive its neighbours of light and air. When trees become too large they should be turned out in the open, and smaller ones substituted. Trees grafted upon suitable stocks for early fruiting do not last long, as the stocks wear out quickly; for instance, pears on the quince stock do not last nearly so long as when on the pear stock; of course, they bear earlier, and that is the sole reason for utilising these early stocks. Good varieties for the orchard house are Beurre Giffard, Clapp's Favourite, William's Bon Chretien, Souv. du Congrès, Louise Bonne of Jersey, Doyenne Boussoch, and Doyenne du Comice pears; Angelina Burdett, Denniston's Superb, Jefferson's, Reine Claude de Bavay, Transparent Gage, Oullin's Golden Gage, Golden Drop, and M'Laughlin Gage plums.

CUCUMBERS. — If these are not yet planted out, let them be dealt with at once. Train them carefully up to the wires by means of a neat stake. Give top-dressings in small quantities regularly, using sweet loam with a little spent mushroom bed manure or decomposed cow dung. The temperature should be kept at about 70 to 75 degrees by means of artificial heat.—W. A. COOK, Leonardslee Gardens.

THE FLOWER GARDEN.

FLOWER BEDS. — Specimen plants of heliotrope, ivy-leaf pelargoniums, fuchsias, etc., which have been growing in the beds during the summer months, should now be lifted and potted. The heliotropiums are the most tender, and should be taken in hand first. All subtropical plants must be removed and placed under cover where they will be out of danger from frosts. As the beds become vacant they should be refilled with wallflowers, bulbs, polyanthuses, or whatever subjects are to be used for the spring display. All beds that are in a poor condition must be enriched with a liberal supply of decayed manure, that is, when wallflowers or polyanthuses are to be grown, as both plants appreciate a rich soil, the polyanthuses preferring decayed cow manure. It is not advisable to add manure to the soil in beds intended for narcissi, but burnt garden refuse and well-rotted leaf-soil can be used instead. When lifting wallflowers one should always endeavour to retain a fair amount of soil about the roots, and if possible a dull day should be chosen for planting. It must be borne in mind that the less check the plants have the quicker they will re-establish themselves, and the loss of foliage will be small. Being such a hardy subject the wallflower is often roughly handled, and consequently does not become sufficiently rooted before the severe weather sets in. Firm planting is another point to remember. A little care and attention goes a long way towards the success of the spring display, and one is amply repaid for the extra time and trouble taken. Regarding bulbs, unless they are planted thickly, it is necessary to carpet the beds to cover the soil; plants suitable for the purpose are aubrietias, arabis, Viola gracilis, myosotis, the mossy saxifragas, and other plants of dwarf habit.

GLADIOLI.—When the foliage shows signs of ripening, the corms should be lifted, as it is not necessary to leave them in the ground until the foliage is absolutely decayed. The best plan is to tie them up in bundles and hang them up in an airy, frost-proof shed, carefully labelling the bundles to prevent confusion when they are being prepared for planting.

ANCHUSA ITALICA and its varieties may be readily propagated now, by cutting up the fleshy roots in exactly the same manner as seakale sets are prepared. These pieces of roots or sets should be dibbled into seed boxes which have been previously filled with sandy soil, and placed in a cold frame.

DELPHINIUMS.—Where it is considered necessary to lift and replant delphiniums the work should be accomplished without delay, so that the plants may become established before the severe weather sets in. As they will probably remain undisturbed for three or more seasons, it is important the ground should be thoroughly dug or trenched and enriched with well-decayed manure before replanting. Great care must be exercised if the roots are to be divided, or much damage will result. A fork thrust into the clump sideways will usually split the woody parts, and one can then pull the pieces apart by hand. Slugs eat the young growths underground during the winter months and early spring, therefore every precaution should be taken to prevent the ravages of these pests. There are several preparations on the market which may be used for the purpose.—E. C. POOLEY, Gnaton Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

On Tuesday, September 26, the Royal Horticultural Hall was filled from end to end with exhibits of varied character and interest. The dahlias and orchids provided rare colour, and ornamental plants and gourds were not less attractive. Vegetables and fruits added their quota of beauty and usefulness, and hardy autumn flowers filled up all the rest of the space.

There was a vegetable show on this date, and the many classes provided were fairly well filled.

FLORAL COMMITTEE.

Across the end of the hall Messrs. Jas. Veitch and Sons, Chelsea, put up a magnificent exhibit of stove and greenhouse plants, one that was excellent both from a cultural and artistic point of view. The background was composed of very tall cocoses with big specimens of Dracæna Goldieana, D. Godseffiana, D. Sanderiana, Anthurium Veitchi, Cocoloba pubescens—with huge leaves, Heliconia illustris rubricaulis, Croton Thompsoni, C. Reidi, etc. In the foreground were splendid examples of nepenthes raised on tall asparagus-clad stands, and these commanded great admiration, especially such handsome kinds as N. Curtisi superba, N. Sir William Thiselton Dyer, N. Mastersiana, N. elegans, N. mixta, and N. Tiveyi. A bright central group of hybrid orchids, with small flanking groups of Lilium speciosum, and cannas and nerines, formed with baskets of choice Rex begonias, bertolonias, Dracæna deremensis Warnecki, crotons, ferns, and selaginellas, a fine frontage to a grand effort.

Michaelmas daisies were extensively shown by Messrs. Barr and Sons, Covent Garden, and their exhibit included Solidago Golden Wings, phloxes, the graceful Vitis Lowi, colchicums, Sternbergia lutea, tritomas, etc.

Mr. Lister, gardener to the Earl of Warwick, Easton Lodge, Dunmow, brought up some very beautiful water lilies of the Stellata section, and two of these named respectively, Listeri and Lord Brooke, were very beautiful; and each gained an A.M.; the latter has deep rosy-mauve orange-centred flowers, and the former is deep blue with a yellow centre. Nymphæa stellata rosea (A.M.) was well shown by Mr. J. Hudson, V.M.H., Gunnersbury House Gardens.

Messrs. Allwood Brothers, Haywards Heath, showed May Day, Mrs. C. F. Raphael, White Wonder, and other good perpetual carnations, including a pale yellow variety of French origin, named Le Jaune Reanente.

Nerine Veitchi (A.M.), a new species with quite large blush white flowers, was shown by Messrs. R. Veitch and Sons, Exeter, who also presented a beautiful new bigeneric hybrid between Cyrtanthus sanguinea and Vallota purpurea; it had semi-pendulous flowers of a pleasing soft orange colour. Nerine Bowdeni and Veronica Veitchi with deep blue flowers were also shown by the Exeter firm.

Messrs. Thos. S. Ware, Lim., Feltham, made a goodly display with pæony-flowered and cactus dahlias, many of their own raising. A very bold display of dahlias from Mr. M. V. Seale, Sevenoaks, was notable for its pretty frontage of small cactus and pompon cactus varieties arranged in baskets of a variety. A big and brilliant bank of great bunches of popular cactus, single, pæony-flowered, and decorative dahlias from Messrs. Carter Page and Co., London Wall, provided a magnificent blaze of colour. Mr. J. T. West, Brentwood, made a great show of dahlias, and put up his new Brentwood Yellow and new pæony-flowered varieties in fine form.

A group of verbenas, in pots, staged by Mr. E. Beckett, V.M.H., gardener to the Hon. Vicary Gibbs, Elstree, once more brought under notice the usefulness of these old florists' flowers. Mr. J. B. Riding, Chingford, again submitted an interesting collection of collarette dahlias. Messrs. Bakers, Wolverhampton, produced a fine blaze of colour with about fifty large bunches of big pæony-flowered dahlias, the colours ranging from white to deep crimson, and including some lovely pink, rose, and fawn shades.

Exquisitely beautiful was the wide run of splendid colchicums from Messrs. James Backhouse and Son, Lim., York. The flowers were grand in their simple loveliness, especially those of C. speciosum album. The typical C. speciosum, C. autumnale, C. a. floribunda, and Crocus speciosus were included in an exhibit that, among hardy flowers, had no equal in the hall. Michaelmas daisies were shown from Mr. H. J. Jones' nurseries, Lewisham, who staged the varieties in large graceful bunches, Ringdove, Mrs. Duncombe Mann, Grace, Grandis, Gaiety, and Perfection, were small-flowered sorts of special elegance and beauty.

Messrs. H. Cannell and Sons, Swanley, contributed a bank of dahlias, and gained an A.M., for a bright crimson-scarlet collarette variety named Hon. Vicary Gibbs. Messrs. J. Cheal and Sons, Crawley, were also extensive exhibitors of dahlias, and made a special feature of pompon-cactus varieties.

Autumn flowers were grouped in quantity by Messrs. William Cutbush and Son, Highgate, and in their display solidagos, Michaelmas daisies, Crinum Powelli alba, Colchicum Bornmulleri, C. speciosum, tritomas, and pentstemons were the leading subjects. Mr. James Box, Lindfield, filled a corner with a very bright group of Michaelmas daisies, Solidago Golden Wings, Artemisia lactiflora, and Helianthus sparsifolius; all good things.

Messrs. H. B. May and Sons, Edmonton, once again contributed a large collection of choice ferns. Phloxes, elegant Michaelmas daisies, carnations, and early chrysanthemums, from Messrs. W. Wells and Co., Merstham, made a bright display.

Mr. G. Reuthe, Keston; Messrs. G. and A. Clark, Dover; and Mr. L. Russell, Richmond (clematis) were also exhibitors.

ORCHID COMMITTEE.

Among the orchids exhibited by Messrs. Sander and Sons, St. Albans, a few of the finer things were Brasso-cattleya Veitchi, Vanda Sanderiana, Cattleya Thayeriana, C. bellatula, C. Dowiana aurea, and Cypripedium insigne Sanderæ.

Oncidium varicosum Rogersi made a pretty background for the group of orchids submitted by Messrs. S. Low and Co., Enfield; here also were Cattleya Gaskelliana alba, C. Iris, Lælio-cattleya Luminosa, Odontioda Thwaitesi, and other good things.

Messrs. Charlesworth and Co., Haywards Heath, presented a few very fine orchids, notably Vanda Marguerite Maron, Cattleya Venus—a glorious variety, Oncidium Lanceanum, and Odontoglossum Harwoodi The Shrubbery var. (F.C.C.), a superb orchid, with yellow flowers, and deep red-brown markings; the three big blotches of velvety red-brown on the broad, rounded lip were wonderfully attractive.

Mr. G. M. Hale, gardener to S. Larkin, Esq., Haslemere, put up a small group of orchids, in which Cattleya Iris and Phalænopsis violacea were leading subjects. From Sir Trevor Lawrence's collection at Burford Lodge, Dorking, Mr. W. H. White brought up finely-grown specimens of Zygopetalum maxillare with about a dozen and a half spikes (Cultural Commendation); Epidendrum floribundum, Epidendrum Lauchianum (A.M.), with two long pendulous spikes of small brown and green and yellow-green flowers.

Mr. Hopkins, gardener to Francis Wellesley, Esq., Westfield, Woking, submitted Cattleya Mrs. Frederick Sassoon (aurea x Mantini nigrescens), which gained an A.M., and is a very hadsome purple and old gold-coloured variety; Cypripedium Dowleri, and Cattleya Gaskelliana Delight.

Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton, submitted a basket of flowering plants of the bright orange-coloured Habenaria militaris, and a Cultural Commendation was granted. From Messrs. Hassall and Co., Southgate, came some well-grown examples of Cattleya Minucia, C. Fabia, C. Nestor, C. Mantini nobilior, L.-c. Walter Gott, and other fine autumn-flowering subjects.

Cypripedium Wiertzianum, with four spikes, and a total of eight big flowers, was the chief attraction among the orchids staged by Mr. E. V. Low, Haywards Heath; C. Rossetti Westonbirt var., C. triumphans, and Cirrhopetalum ornatissimum were included in the exhibit. A plant of Odontoglossum Memoria Baron Schröder, the committee asked to see again, as the flowers were not yet fully open.

Mr. J. Day, gardener to H. S. Goodson, Esq., brought up Lælio-cattleya St. Gothard, and a few other good things.

FRUIT AND VEGETABLE COMMITTEE.

A vastly interesting and extensive exhibit of ornamental gourds from Mr. Thos. Stevenson, gardener to E. A. Mocatta, Esq., Woburn Place, Addlestone, was a distinct feature of the show. The display filled a space about 36ft. by 6ft., and there were about two tons of gourds, many of them two feet and upwards in diameter; while others were quite tiny, only an inch or so across. Some were so heavy, like the Giant Red Etampes, Giant Paris, Portuguese, Grey Boulogne, and other huge gourds, that they tipped the beam at from 50lb. to 89lb. each. In shape, too, there was a wonderful variety, some were round, others like the Snake Gourd, measured 5ft. in length; some were like Indian clubs, others resembled oranges, gooseberries, pears, dumb-bells, eggs, bottles, clubs, pipes, syphons, etc. In colour there was a range from white and pale-green to deep crimson, bright gold, and dark purple. The arrangement of the group was excellent, and we feel sure no such collection of ornamental gourds as this one of some seventy varieties has ever been placed before the public in this country. Our readers will remember that at Woburn Place a big pergola is annually devoted to these gourds.

Mr. James Whittle, gardener to Lieut.-Colonel A. C. Borton, Chevening, Hunton, Maidstone, put up an unusually fine exhibit of fruit, and tastefully disposed his splendid samples in flat, handled, and round baskets, and on dishes of various sizes. Apples, pears, plums, damsons, crabs, blackberries, nuts, and peaches were included. Among apples we noted superb fruits of Mère de Ménage, Warner's King, Newton Wonder, Wealthy, Belle Dubois, Gascoyne's Scarlet, Rival, Emperor Alexander, Lady Henniker, The Queen, Alfriston, Allington Pippin, Blenheim Pippin, Cox's Orange Pippin, King of the Pippins, Mabbot's Pearmain, and Ribston Pippin.

A large and particularly well displayed collection of vegetables from Messrs. Sutton and Sons, Reading, was a very attractive and interesting feature. The numerous kinds were arranged in three broad tiers, and every dish was of the finest quality. The staging was most tasteful. A few vegetables that commanded special attention were Michaelmas White broccoli and Autumn Mammoth cauliflowers; Satisfaction, Abundance, Perfection, and Eclipse tomatoes; A1., Sutton's Scarlet, Prizewinner, and Best of All runner beans; Ailsa Craig onions; Gladstone peas; Sutton's Black beet—very fine; Sutton's Heartwell lettuce; and radishes in great variety.

The large and well-arranged collection of vegetables contributed by Messrs. James Veitch and Sons, Chelsea, was bright with baskets of Invicta, Ham Green Favourite, The Hastings, Sunset, and Sunnybank tomatoes, Autumn Giant cauliflowers, Hackwood Park runner beans of great length and very straight and fleshy, Ailsa Craig onions, Defiance marrows, and ornamental gourds, with carrots, beet, potatoes, etc., made up a fine display.

The exhibit of vegetables from Messrs. Barr and Sons, Covent Garden, was a good one, and of special merit were the dishes of Invincta runner beans, Winningstadt cabbages, Ailsa Craig onions, Autumn Giant cauliflowers, Corn Cobs, and Solid Pink celery.

Mr. Harris, gardener to A. W. Sutton, Esq., Bucklersbury Place, Reading, showed excellent orchard fruits of Lord Derby, New Hawthornden, Lady Sudeley, Gascoyne's Scarlet, and Newton Wonder apples.

Mr. E. Neal, gardener to J. A. Nix, Esq., Tilgate, Crawley, showed a collection of fruits wherein apples were the chief features, but with these were good bunches of Alicante, Madresfield Court, Mrs. Pince, and Gros Maroc grapes; Nectarine, Walburton Admirable, and Princess of Wales peaches; as well as melons, pears, and plums.

Mr. G. Reynolds, gardener to Leopold de Rothschild, Esq., Gunnersbury Park, Acton, presented an exhibit of very choice fruits that included ten Queen pineapples, seven fine specimens of Gunnersbury Whiteflesh melons, and good dishes of Lady Palmerston, Albatross, Gladstone, Thomas Rivers, Nectarine, and Princess of Wales peaches.

Hardy fruits were excellently well shown by Messrs. G. Bunyard and Co., Maidstone, the examples being large, clean, and bright; Twenty-ounce, Norfolk Beauty, Emperor Alexander, Prince Alfred, Wealthy, Gascoyne's Scarlet, and Peasgood's Nonsuch were grand among the apples, while of pears the best were Marguerite Marillat, White Doyenne, Durondeau, Pres. Osmanville, Conference, and seven fruits of Uvedale's St. Germain that weighed 12lbs. together.

Messrs. Laxton Bros., Bedford, exhibited their new Laxton Berry, the result of crossing Superlative raspberry with the Loganberry. The fruits are of raspberry character, and come away from the core freely; they are reddish, and though not so sweet as raspberries, they are more pleasant than those of the loganberry. It has the habit of growth of the loganberry, and is perpetual fruiting from June to November—we saw the parent plant in fruit at Bedford in early November two years ago. Large fruiting sprays were submitted on this occasion.

A score of handsomely netted fruits of Barnet Hill melon, exhibited by Mr. Mitchelson, gardener to F. H. Cook, Esq., Guildford, merited a silver Banksian medal.

CERTIFICATES AND AWARDS.

First-class Certificate.—To Odontoglossum Harwoodi, The Shrubbery variety, from Messrs. Charlesworth and Co., Haywards Heath.

Award of Merit.—To Cattleya Mrs. Frederick Sassoon, from F. Wellesley, Esq., J.P., Westfield, Woking; to Epidendrum Laucheanum, from Sir Trevor Lawrence, Bart., Burford Lodge, Dorking; to Nerine Veitchi, from Messrs. R. Veitch and Sons, Exeter; to Collarette dahlia Prince de Venosa, from Messrs. Dobbie and Co., Edinburgh; to single dahlia Queen of the Mauves, from Mr. M. V. Seal, Sevenoaks; to single dahlia Mahdi, from Messrs. J. Cheal and Sons, Crawley; to cactus dahlias Uranus, Golden Wave, and Stability, from Messrs. J. Stredwick and Son, St. Leonards; to Nymphaea Listeri and N. Lord Brook, from Mr. Lister, gardener to the Earl of Warwick, Easton Lodge, Dunmow; to Nymphaea stellata rosea, from Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton; to Rose Rayon d'Or, from Messrs. Paul and Son, Cheshunt; to potato Dobbies' Prolific (after trial at Wisley, and cooking test at Westminster), from Messrs. Dobbie and Co., Edinburgh.

MEDALS.

Gold.—To Messrs. J. Veitch and Sons, Chelsea, for stove and greenhouse plants; to Messrs. Sutton and Sons, Reading, for vegetables; to Mr. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, for ornamental gourds.

Silver-gilt Knightian.—To Messrs. G. Bunyard and Co., Maidstone, for fruits; to J. A. Nix, Esq., Crawley, for fruits.

Silver-gilt Banksian.—To Messrs. J. Cheal and Sons, Crawley, for dahlias; to Messrs. W. Cutbush and Son, Highgate, for autumn flowers; to Messrs. J. Veitch and Sons, Chelsea, for vegetables; to Mr. G. Reynolds, gardener to Leopold de Rothschild, Gunnersbury Park, Acton, for peaches and pineapples.

Silver Flora. — To Messrs. J. Backhouse and Son, York, for colchicums; to Messrs. Carter Page and Co., London Wall, for dahlias; to Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, Elstree, for verbenas; to Messrs. H. B. May and Sons, Edmonton, for ferns.

Silver Knightian.—To Messrs. Barr and Sons, Covent Garden, for vegetables.

Silver Banksian.—To Mr. J. Box, Lindfield, for hardy flowers; to Messrs. H. Cannell and Sons, Swanley, for dahlias; to Mr. M. V. Seale, Sevenoaks, for dahlias; to Mr. J. T. West, Brentwood, for dahlias; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. S. Low and Co., Enfield, for orchids; to Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Hassall and Co., Southgate, for orchids; to S. Larkin, Esq., Haslemere, for orchids; to Mr. Mitchelson, gardener to F. H. Cook, Esq., Guildford, for melons.

Bronze Flora.—To Messrs. Bakers, Wolverhampton, for dahlias; to Mr. L. R. Russell, Richmond, for clematis; to Mr. C. Turner, Slough, for pampas grass.

Bronze Banksian.—To Messrs. Barr and Sons, Covent Garden, for hardy flowers; to Messrs. Thomas S. Ware, Lim., Feltham, for dahlias, etc.; to Messrs. W. Wells and Co., Merstham, for hardy flowers, etc.; to Mr. J. B. Riding, Chingford, for dahlias.

VEGETABLE SHOW.

The competitive classes for vegetables on September 26 were in most cases well filled, though this could hardly be said of those for collections. On the whole, the quality was quite up to the average, especially was this noticeable in the bulb and root classes.

In the premier class for twelve distinct kinds there were but three competitors. The first prize was awarded Mr. J. Gibson, gardener to the Duke of Portland, Welbeck Abbey, who had a superb collection. His examples of Solid White celery, Autumn Mammoth cauliflower, Prizetaker leeks, Black beet, Ailsa Craig onions, The Student parsnip, Perfection tomato, Delicacy cucumber, New Red Intermediate carrot, and Satisfaction potatoes were almost perfect.

The silver cup for nine kinds, distinct, was awarded to Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, who staged a splendid collection of Superb Pink celery, Early Giant cauliflower, Prizetaker leeks, Tender and True parsnips, Ailsa Craig onions, New Red Intermediate carrots, Dwarf Gem Brussels sprouts, Satisfaction tomatoes, and Windsor Castle potatoes. Mr. W. Gaiger, gardener to Mr. H. T. Tatham, Kendall Hall, Elstree, was a good second, his special features were Lyon leeks Ailsa Craig onions, Autumn Giant cauliflower, and Cheltenham Green Top beet. Mr. W. Folkes, Ampthill, Beds, was a good third, his carrots being very fine.

For six distinct kinds there was a good competition, but Mr. Geo. Ellwood, gardener to Mr. W. H. Myers, Swanmore Park, Bishop's Waltham, won first position with good clean examples of Superb Pink celery, Prizetaker leeks, Autumn Mammoth cauliflower, Sutton's Superlative potato, Ailsa Craig onions, and Perfection tomato. Mr. T. Avery, gardener to Mr. J. Kerr, Loudwater, Rickmansworth, came second with good examples of Ailsa Craig onion, Perfection tomatoes, and good carrots. Mr. A. Keep, Aldermaston, near Reading, was third; and Mr. H. Smith, gardener to Mr. B. Henderson, Epping House, Little Berkhamsted, fourth. There were but three collections of potatoes, six varieties, but all were of excellent quality. Mr. E. Beckett was awarded first with good clean tubers; the varieties were Windsor Castle, King Edward VII., Sutton's Ideal, Abundance, Edgecote Purple, and Early Puritan. Mr. George Ellwood was second with splendid dishes of Superlative, Ideal, and White City; while Mr. W. Gaiger was third.

The collections of six varieties of onions appeared to be popular, judging by the entries. Mr. E. Beckett won first prize with large, well-finished dishes of Improved Reading, Perfection, Ailsa Craig, Sutton's A1., Sutton's Globe, and Red Rocca. Mr. J. Gibson was a capital second; his best dishes were The Globe, Magnum Bonum, and Ailsa Craig. Mr. G. Hatch, gardener to Mr. A. B. H. Goldschmidt, Caverham Park, Mildenhall, proved a good third.

For a collection of nine kinds of salads Mr. E. Beckett won premier honours with quite a smart exhibit. It consisted of lettuces, endive, celery, beet, mustard, cress, tomatoes, radishes, and cucumbers. Mr. W. Gaiger was second with good lettuces, tomatoes, and endive. Mr. Geo. Ellwood led off for a similar class of six varieties with a nice well-grown collection. The best dishes were French Breakfast radish, Sutton's Black beet, and Batavian endive. Mr. H. Smith was placed second with good endive and tomatoes.

For six other vegetables than these scheduled distinct, Mr. E. Beckett was again most successful, staging Egg Plant Long Purple, Celeriac, Purple Kohl Rabi, scorzonera, salsify, and Golden Dawn Capsicum. Mr. Geo. Ellwood was second with fine dishes of Long Red Chili, Celeriac, and Kohl Rabi. Mr. R. Brown, gardener to Lady Tress Barry, St. Leonards Hill, Windsor, was third.

The competition for a dish of scarlet runners brought out a large display, Mr. J. Gibson securing first for Prizewinner, a very fine bean; Mr. E. Beckett was second. Mr. J. T. Tubb, gardener to Mr. J. D. Alexander, Oakbank, Sevenoaks, won first prize with Tender and True, a beautiful colour. Mr. J. Gibson was most successful in beet with fine long roots of Sutton's Black. The same exhibitor also secured the first prizes for a dish of sprouts, and three plants, in both cases staging Dwarf Gem, some wonderful buttons for the season. Cabbages were good, Mr. A. Basile winning well with Early Rainham, perfect models, without a caterpillar mark. The best savoys were from Mr. J. Gibson, who had really good specimens of Perfection. There were eleven entries. Mr. E. Beckett was again to the fore for a brace of cucumbers with a pair of Matchless; Mr. T. Avery was a close second.

Although there were only three entries for leeks, the specimens staged were superb, Mr. E. Beckett securing first with Prizetaker. Mr. G. Ellwood following with the same sort. Mr. A. Basile was first for three marrows with a level trio; some of the others were quite ripe. Mrs. H. Pryce, 43, Willow Street, Westminster, was awarded first prize for mushrooms, a very good lot. For a dish of round onions Mr. G. W. Taylor, gardener to Mr. A. Banks, Wolfeton House, Dorchester, was awarded first for six splendid bulbs of Ailsa Craig, Mr. J. T. Tubb being second, and Mr. E. Beckett third. Mr. G. Ellwood was most successful in the flat type with well-finished examples of Sutton's A1. Mr. J. Gibson second with the same variety. There was a good entry for parsnips, Mr. E. Beckett having good examples of Tender and True. Mr. G. Ellwood followed, and Mr. J. Gibson brought up the rear.

Mr. J. Gibson led for carrots with New Red Intermediate; Mr. A. G. Gentle, gardener to Mrs. Denison, Little Gaddesden, Berkhamsted, being second with Red Elephant. Mr. G. Ellwood won first place in the stump-rooted class; while Mr. J. Gibson was most successful with peas, staging The Gladstone; Mr. E. Beckett was second. There were five dishes of turnips, Mr. E. Beckett being first with Early Snowball. Red tomatoes were very good. Mr. E. Beckett led off with a fine dish of Satisfaction; Mr.

Ellwood second with the same variety. Mr. Beckett was again to the fore with a good, well-coloured dish. For a dish of "Any other vegetable," Mr. E. Beckett led with some splendid Corn Cobs: Mr. R. Brown second with Silver Spinach beet; and Mr. A. G. Gentle third with red cabbage. The prize for kale was won by Mr. W. Gaiger.

SCIENTIFIC COMMITTEE.

September 13.—Present: Mr. A. W. Hill, M.A. (in the chair); Messrs. J. O'Brien, J. Fraser, and F. J. Chittenden (hon. sec.).

BULBOPHYLLUM ORTHOGLOSSUM.—Mr. J. O'Brien drew attention to this uncommon species (figured in the "Gardeners' Chronicle" some time ago) shown by Sir Jeremiah Colman, Bart., which had been imported from the Phillipine Islands.

GALL ON TANACETUM, ETC.—Mr. J. Fraser showed specimens of a gall on Tanacetum vulgare formed by the fly Hormomyia tanaceticola, both on the stem and in the leaf axils. It had been collected on the Thames bank near Richmond. He also showed the fasciated stem of a vegetable marrow showing about forty ridges. Mr. Fraser remarked concerning the perpetuation of abnormalities that many appeared to depend upon merely local conditions, and could not be perpetuated, e.g., although he made cuttings from the abnormal stem of the mint he showed last year with leaves displaced and showing other abnormalities, they had reproduced the normal type entirely this season.

QUINCE WITH FELTED GROWTH.—Mr. Fraser also showed a quince covered with hairy growth, somewhat similar to that seen on the young fruits, but here persisting to a late period.

OATS AND BARLEY SHOOTING AFTER HARVEST.—Mrs. E. Robertson sent specimens of oats and barley making a second growth after the harvest had been cut. The growth sprung from below the main stem, and bore flowers at the height of about a foot. They were collected at Limavady, Co. Derry.

Manchester and North of England Orchid Society.

At the meeting held at the Coal Exchange, Market Place, Manchester, on Thursday, September 14, the members of committee present were: Z. A. Ward, Esq. (in the chair), Messrs. R. Ashworth, W. R. Lee, C. Parker, H. Thorp, J. C. Cowan, J. Cypher, W. Holmes, A. J. Keeling, F. K. Sander, and H. Arthur (secretary).

Z. A. Ward, Esq., Northenden (gardener, Mr. Weatherby), was awarded a silver gilt medal for a magnificent group of cattleyas of the Iris section, prominent amongst which was a fine form, Ward's var., to which a F.C.C. was given—a large flower, brilliant in colour, with intense lip. Amongst the cypripediums were noticed C. Rossetti, C. triumphans, and C. Leeanum var. Corona. A cultural certificate and bronze medal were granted to the gardener for the excellent growth of the cattleyas in the group.

Colonel J. Rutherford, M.P., Blackburn (gardener, Mr. Lupton), staged a nice group, to which a silver medal was awarded, cattleyas and cypripediums being represented; Cattleya Gaskelliana alba, C. Dominianum Langleyense, and C. Iris sanguineum were very good, as were also Cypripedium Rossetti, C. Chorltoni, and Lycaste Skinneri alba.

W. R. Lee, Esq., Heywood (gardener, Mr. Woodhouse), was awarded a silver medal for a group of choice plants; Cattleya Thurgoodianum, var. nobilior (F.C.C.), C. Gaskelliana alba, C. Mrs. John Leeman (aurea x Digbyana), C. Maqueda (A.M.), Dendrobium phalænopsis Colmani (F.C.C.), Cypripedium Rossetti, C. Iris (Plumpton Hall var), and C. Bingleyense, amongst others, making a nice display.

Dr. Hodgkinson, Wilmslow (gardener, Mr. Moore), staged an interesting plant of Lælia tenejalis (grandis tenebrosa x majalis). A.M. R. Ashworth, Esq., Newchurch (gardener, Mr. Gilden), staged a plant of Catasetum macrocarpum, an unnamed var. (A.M.) J. McCartney, Esq., Bolton (gardener, Mr. Holmes), staged Lælio-cattleya rubens, var. magnifica (A.M.), a good variety.

Messrs. J. Cypher and Sons, Cheltenham, were awarded a silver medal for a group containing some nice Cypripedium triumphans, C. Niobe superbum, C. Milo, C. Leonæ, C. Farrieanum, Miltonia spectabilis Morelliana, a nice dark variety, Vanda cærulea, Odontoglossum grande, and a nice plant of Phaio-Cymbidium Chardwarense.

Messrs. Keeling and Sons, Bradford, staged a group to which a bronze medal was awarded, cypripediums predominating; C. Kimballianum, C. Lord Derby, C. Rolfæ superbum, C. Charlesworthi, C. Milo superbum, C. Arthurianum, C. Hitchensæ, and C. gigas, Corndean var., being the best; Oncidium microchilum, with a fine spike, was very interesting.

Messrs. Hassall and Co., Southgate, staged a few plants of merit, a plant of Cattleya iridescens (bicolor x Eldorado), var. cuprea (A.M.) being especially noticeable; with other new hybrids not named.

Mr. Edward V. Low, Haywards Heath, staged Cattleya Gaskelliana, var. Phyllis, Cattleya Adula, a fine variety, Cypripedium mirabilis, and C. Amboyne. Mr. W. Shackleton, Great Horton, Bradford, staged a plant of Cypripedium Lord Ossulston, Chillingham var.

The next meeting will be held in the Coal Exchange, Manchester, on Thursday, September 28th, 1911.

AWARDS.

First-class Certificate. — To Cattleya Thurgoodianum, var. Nobilior, from W. R. Lee, Esq., Heywood (gardener, Mr. Woodhouse), a splendid flower of good form and substance; to Dendrobium Phalænopsis Colmani, from the same exhibitor, a large full flower, well lined in the lip. To Cattleya Iris, Ward's var., from Z. A. Ward, Esq., Northenden (gardener, Mr. Weatherby), one of the finest forms of the type seen, sepals and petals very brilliant in colour and intense colour in lip.

Award of Merit.—To Lælio-cattleya Maqueda (Geo. Woodhams x Lord Rothschild), from W. R. Lee, Esq. (gardener, Mr. Woodhouse), an excellent form, very even in colour; to Cattleya Adula, var. Maroni, from Z. A. Ward, Esq. (gardener, Mr. Weatherby); to Cattleya Iris, St. Giles, and C. No. 3, both fine forms, from the same exhibitor; to Lælia tenejalis (grandis tenebrosa x majalis), from Dr. Hodgkinson, Wilmslow (gardener, Mr. Moore), a large flower of deep colour; to Catasetum macrocarpum, from R. Ashworth, Esq. (gardener, Mr. Gilden), a well-flowered plant of a supposed new variety; to L.-c. Rubens, var. magnifica, from J. McCartney, Esq., Bolton (gardener, Mr. Holmes), a very nice variety, of good form; to Cattleya Iridescens, var. cuprea (bicolor x Eldorado), from Messrs. Hassall and Co., Southgate, a very nice form, brilliant in colour; to Miltonia Crashlayana, var. albus, from Messrs. A. J. Keeling and Sons, Bradford.

Reading Gardeners' Association.

The opening meeting of the autumn session of this association was held in the Abbey Hall (by kind permission of Messrs. Sutton and Sons). The President (Mr. F. B. Parfitt, J.P.), occupied the chair, and there was a very large attendance. Among the matters which received attention previous to the usual lecture was the presentation of certificates to the successful candidates at the examination held at the conclusion of the evening classes conducted under the auspices of the Reading University College last winter and spring. The successful members were Messrs. B. Fletcher, F. H. Fordham, P. Judd, E. J. Dore, and G. Chambers. A hearty vote of thanks was accorded Mr. F. G. Drew, horticultural instructor at the College, for so kindly undertaking this course of lectures.

The speaker for the evening was Mr. Alexander Dean, V.M.H., who was listened to with close attention by the large and appreciative audience. His subject was "Floral Ideals," and after a short introduction, in which he explained the meaning of the term "florist flowers," as generally understood, he proceeded to give an exhaustive address exemplifying the long and patient efforts of the horticulturists of fifty or sixty years ago in the production of what they considered to be perfection of form and colour in various flowers. Their ideals demanded perfect symmetry in appearance with precision and regularity in marking. Modern ideas of artistic beauty tend in the opposite direction; indeed, the lecturer remarked, the shaggy and uneven cactus and other dahlias which were staged before him would appeal but little to Glenny and his contemporaries, and he (Mr. Dean) confessed that his sympathies were all with the old notions, and contended that many beautiful ideals of the florist of fifty or sixty years ago had been by his modern successor "improved" (?) almost beyond recognition. The present generation aimed at size, and to secure this was prepared to sacrifice not only form but that delightful attribute of nearly all flowers, their lovely perfume. As types of successful culture and selection he instanced auriculas, gold-laced polyanthus, carnations, hollyhocks, dahlias, pansies, violas, pentstemons, primulas, sweet peas, and roses, fully explaining the points aimed at by the florists in the production of perfect blooms of each species.

At the conclusion of his remarks Mr. Dean was loudly applauded, and, on the proposition of the Vice-chairman, seconded by Mr. Tunbridge, a vote of thanks was accorded him.

A certificate of cultural merit was awarded to Mr. A. Giles, gardener to Mr. H. Dunlop, for an exhibit of twelve cactus dahlias. Mr. F. Townsend, head gardener to the vice-president, staged some very fine blooms of seedling dahlias, which were greatly admired, and Mr. Bailey, gardener to H. Collins, Esq., exhibited interesting flowers of Nerine Fothergilli majus.

TRADE NOTE.

Mr. James Box, of Lindfield, sends us a very appreciative letter anent our report of his exhibit at the recent R.H.S. meeting. He humorously remarks that his "special arrangement with the Clerk of the Weather" was the acquisition of 4½ acres of meadow land last winter, trenching 3ft. deep, and adding plenty of manure during the process. This spade work has kept his hardy perennials going strong all through the dry weather, for at Lindfield there has not been two inches of rain since April 5.

FORTHCOMING ENGAGEMENTS.

TUESDAY, October 3.—Scottish Horticultural Association.
WEDNESDAY, October 4.—National Chrysanthemum Society, Crystal Palace; two days.
SATURDAY, October 7.—French Horticultural Society of London.

CATALOGUES RECEIVED.

DANIELS BROTHERS, LIM., NORWICH.—Commencing with bulbs for forcing, and running through the various kinds of bulbs, this catalogue also includes lists of fruit trees, roses, ornamental trees and shrubs, hardy perennials, and stove and greenhouse plants, and therefore makes a very comprehensive list; there are numerous illustrations.

A. BERNAIS, LYONS, FRANCE.—Rose growers will find this catalogue, printed in English, an interesting one, because it contains descriptions of a large number of Continental roses, as well as British ones.

JOHN K. KING AND SONS, COGGESHALL, ESSEX.—Of handy size for the pocket, this catalogue of bulbs comes to us under the title of "Beautiful Heralds of Spring." Roses, fruit trees, and herbaceous plants are also listed.

CHARLES TURNER, SLOUGH.—Hyacinths, retarded bulbs, and roots for forcing, irises and liliums, are special features of the bulb catalogue from Slough.

DICKSONS, CHESTER.—The illustrations of hyacinths and tulips, as well as those of other bulbs, make the Chester list a very attractive and useful one.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

NATIONAL SWEET PEA SOCIETY.—C. H. H., Eastbourne. Your letter has been forwarded to the proper quarter, and no doubt you will have received an answer ere these lines appear.

POTERIUM TENUIFOLIUM.—T., Kells. A white variety of Poterium tenuifolium is recognised, and you will find it listed in the "Kew Handlist of Herbaceous Plants." The type has pink or purplish flowers.

BULB CULTURE.—M. E. M., Altrincham: A useful book for your purpose is "Bulbs and Their Cultivation," to be obtained, post free, for 2s. 10d., from W. H. and L. Collingridge, 148, 149, Aldersgate Street, E.C.

CLIMBER FOR OLD PEAR TREE.—R. N. B., Haslemere: There are numerous climbers which, if carefully planted near the foot of the dead pear tree, would soon cover the trunk and chief branches with beauty. Clematis montana, C. m. rubens, C. flammula, C. vitalba, and C. Jackmanni would be all suitable. Another delightful climber for such a purpose is Polygonum baldschuanicum.

SECONDARY GROWTH IN CATTLEYAS.—A., Manchester: You will find the matter dealt with in detail and at some length in a special article in the present issue.

WEED KILLER.—G. E. S.: We do not know the composition of the lawn sand used for the destruction of daisies, etc., on lawns.

HARDY YELLOW JASMINES.—M. E. G., Hemel Hempstead: There are four or five hardy jasmines in addition to the ever popular winter-flowering Jasminum nudiflorum, and excluding the semi-hardy J. primulinum. These are J. floridum, a useful Chinese shrub; J. fruticans, a semi-climbing native of Southern Europe; J. humile, a deciduous Indian species, that like all the former, is summer flowering; J. odoratissimum, a Madeiran plant that is not hardy in the north; and J. revolutum, an evergreen fragrant species that needs wall protection in the north.

THE BLUE THROAT-WORT.—H. G., Boston: Many years ago the Blue Throatwort, Trachelium cæruleum, was a very popular greenhouse plant, and was quite largely grown for the decoration of the conservatory in the summer. It is a most easily-grown plant, and may be propagated from seeds sown in the autumn or spring, in a warm greenhouse; cuttings of young growth inserted in sandy soil in early summer offer another means of increase, while division of the roots some while after the flowering stems have been cut down generally proves successful. For the greater part of the year established plants need nothing more than cold frame protection. Plants in 48-sized pots are quite large enough for general decorative purposes. Sandy loam and leaf-soil form a suitable compost.

CANKER IN LORD SUFFIELD APPLE.—P. C., Dunoon: It appears that in the North this fine apple rarely lives to a good age, but mostly succumbs to canker about ten or a dozen years after planting, or, if it does not succumb to the disease it is so debilitated as to be unprofitable. Under fairly good conditions it becomes established early, and grows freely, and crops well for the first eight or nine years, but usually soon loses vigour after that period. It is, however, such a free bearer that it would probably pay to keep up a young stock of trees in a private garden, and regularly discard those beginning to fail. James Weish is considered an excellent variety to substitute for Lord Suffield in the South of Scotland.

NAMES OF PLANTS.

H. B. M., Bersted.—Nandina domestica.

G. L. S., Petersfield.—1, Pyrus aucuparia; 2, P. Aria.

M. C., Norwich.—1, Phygelius capensis; 2, Chrysanthemum uliginosum.

H. B., Nottingham.—1. Artemisia lactiflora; 2, Cornus Spathi; 3, Olearia Haasti.

E. B., Bognor.—We cannot undertake to name florists' flowers; your best plan will be to send blooms to a nurseryman who specialises in dahlias.

C. O., Fairford.—The plant is an Asarum, probably Asarum canadense, the Canadian Snakeroot. The asarums belong to the natural order Aristolochiaceæ.

NAMES OF FRUITS.

Correspondents not answered in the present number will please consult subsequent issues.

S. S., Leeds.—Peasgood's Nonsuch.

A. D. L., Huntstanton.—1, Blenheim Pippin; 2, Warner's King.

F. E. J., Cleethorpes.—1, Beurre Clairgeau; 2, Beurre Diel; 3, Lane's Prince Albert.

V. F., Ipswich.—1, Hollandbury; 2, Ribston Pippin; 3, Louise Bonne of Jersey; 4, Ecklinville.

F. R. O., Reading.—1, Cox's Orange Pippin; 2, King of the Pippins; 3, Adam's Pearmain; 4, Marie Louise; 5, Blue Imperatrice.

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price **10/6.** Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

MIDDLETON, MANCHESTER.

RANSOMES' LAWN SWEEPERS

have proved themselves most effective in use, and economical in time, as compared with the tedious process of sweeping by hand. To meet the demand which has arisen for a lighter and cheaper machine, R. S. & J., Ltd., have brought out the one illustrated, in which the driving is done by two side wheels and a canvas collector is fitted so that the weight is reduced and the draught considerably lightened.

Width - 24 in.
Easily worked by one man.

**MODERN
GLASSHOUSES**

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

Printed and Published by W. H. & L. COLLINGRIDGE, City Press, 148 & 149, Aldersgate St., London, E.C., and sold by all Newsagents, and at all Railway Bookstalls

THE GARDENERS' MAGAZINE.

No. 3,023. Vol. LIV. (Reg. at the G.P.O. as a Newspaper, and for Canadian Magazine Post.) SATURDAY, OCT. 7, 1911. (10/6 per Ann. Post Free. To Foreign Countries, 15/-.) **Twopence**

MY SWEET PEA LIST

will be the most time-saving, interesting, profitable, and pleasure-giving list in the world. Post-card commands it.

I am being honoured with **novelties** from Aitken's, Chapman, Cole, Burpee, Deal, Dobbies, Hemus, Lumley, Stark, Trevethick, Ward, and many others

My stock of last year's novelties are, with few exceptions, English grown and rogued by **genuine Sweet Pea lovers.**

My Special Spencer Mixture contains Earl Spencer, Nancy Perkin, Syeira Lee, Thomas Stevenson, Dainty, and Helen Pierce Spencers, etc. This I **guarantee. 1s.** per oz., **1s. 10d.** per 2oz., **3s. 6d.** per 4oz., post free.

My Helen Pierce Spencer Seedlings will be a source of profit and pleasure to the grower. The stock has been rogued down to Spencers at great expense. A selection from this mixture properly fixed will make a small fortune for the owner. **1s. 6d.** per oz., **2s. 6d.** per 2oz., post free.

My Special Seedling Spencer Hybrid Mixture is from two of our keenest British hybridists, who have more stock than they can possibly handle as it ought to be. **Such seed never offered before. 1s. 6d.** per oz., 2oz. for **2s. 6d.,** post free, worth 10s. per oz., as it is absolutely the result of their life's work. Virtually selling proverbial £1 for one penny.

Sole distributing agent for Mr. F. Herbert Chapman's Iolanthe, the most opaque white Sweet Pea in existence. 8 seeds, **6d.**; 20 seeds, **1s.**

I hope to have my list ready early in October.

CLEANLY

AND INTERESTING, A CHARMING WAY OF GROWING BULBS FOR TABLE AND ROOM DECORATION.

—— a dainty bowl, a few bulbs of either Hyacinths, Tulips, Narcissi, Crocus, Scillas, Jonquils, and others, or a few Lily of the Valley crowns, a compost we specially prepare, and regular attention to watering, and there will result an effective group of beautiful flowers and clean bright foliage, which can be placed anywhere without the least risk of damage to covering or furniture. We offer the bowls in a variety of shapes and colours, each with sufficient of our compost, at 1/6, 2/-, 2/6, 3/- each, and upwards, and we have an excellent range of suitable bulbs.

See page 2 of our Catalogue (free) for fuller particulars.

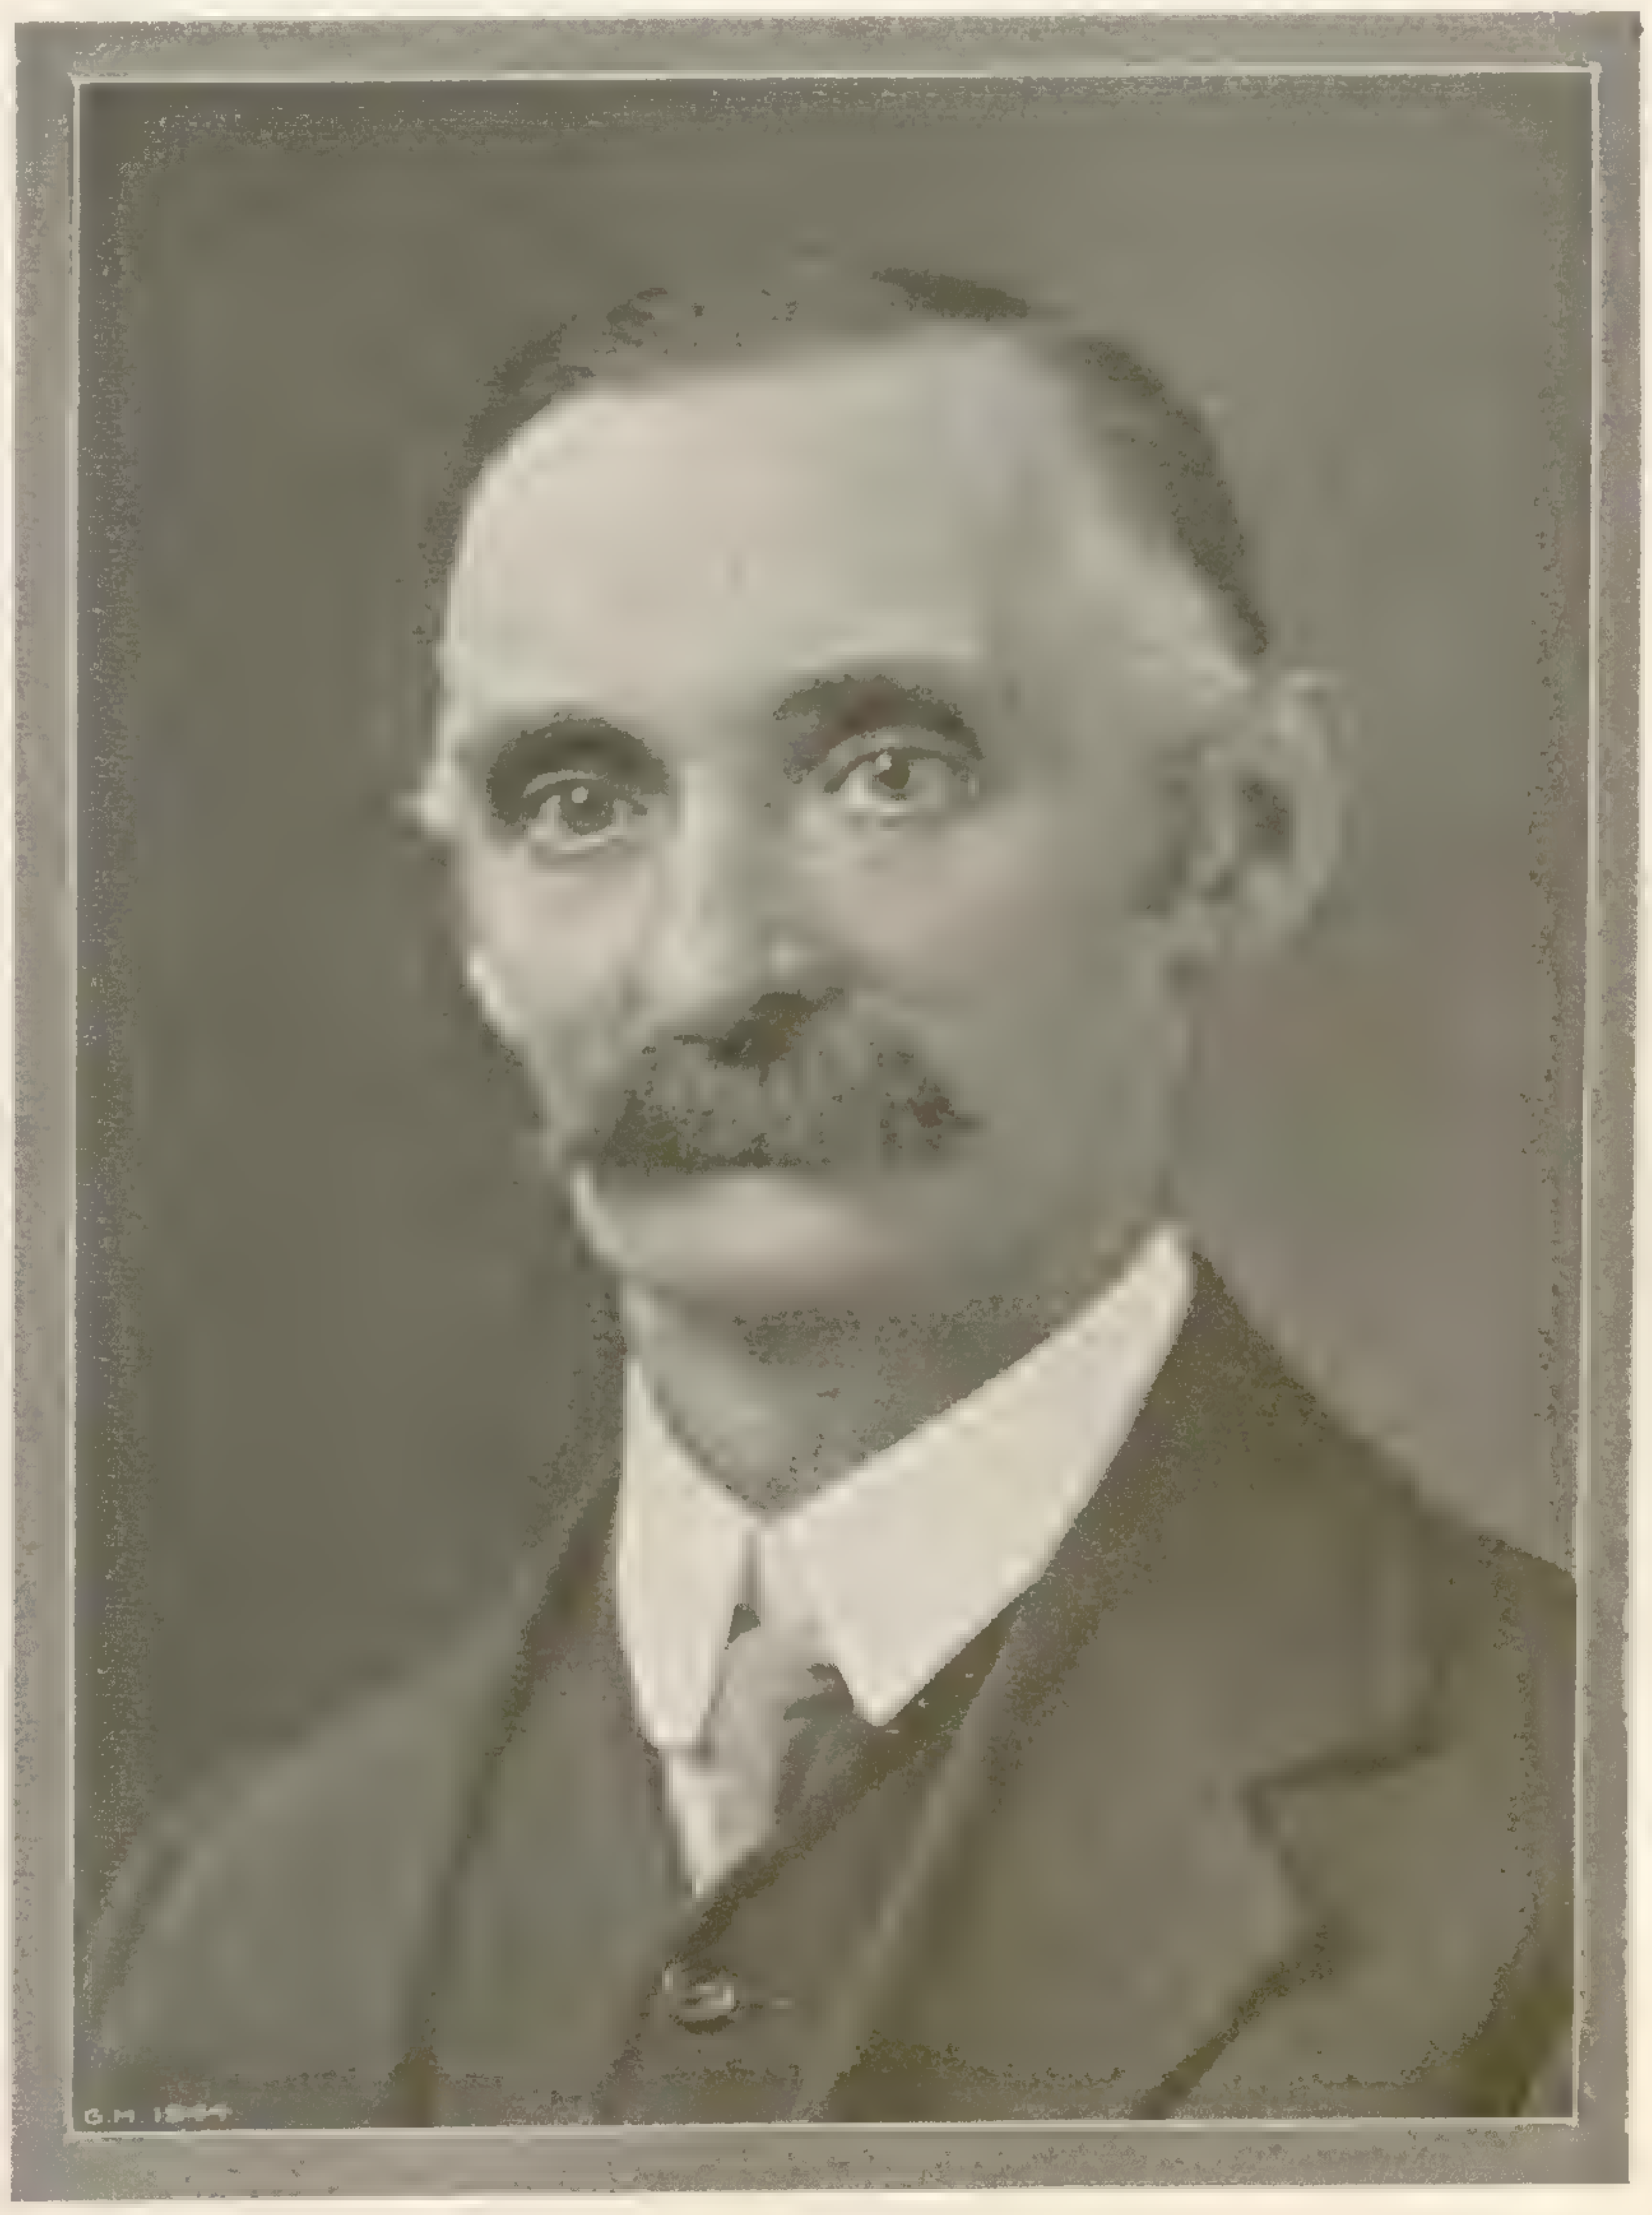
THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Sunbeams.



MR. J. T. BARKER.

The abundance, indeed we may almost say superabundance, of sunbeams, with which we have been blest, or otherwise, during the past months, has been without equal during the lives of most of us, and we have, therefore, had a special opportunity of judging of its effects. On the whole, of course, it has undoubtedly been beneficial; sunshine is the source, or rather medium, of all vitality, so far as the earth is concerned; its rays bring to us all the stimulant energy by virtue of which we exist. The very rainfall, which modifies its otherwise drastic effects, is lifted up and wafted to us by its influence: and all the wonderful diversity, not merely of organic life, but of inorganic existence, as exemplified by our hills and vales, mountains, deep ravines, and canons, etc., has been shaped, and even created, by the subtle influence of the sunbeam working through æons of time, both on the liquids and solids, which constitute the terrestrial crust. In point of fact, there is no effect of which search sufficiently deep would not reach the sunbeam as the cause. Its potency underlies everything on earth, and constitutes, the Creator of the Universe apart, the great primary cause of everything. Withdraw its heat entirely and we have a frozen lifeless world; and trace back the history of that world and science will tell us that it begins practically as a mass of ethereal sunshine, the very matter incorporated with it existing then as intangible luminosity. Leaving, however, these somewhat recondite considerations, we will confine ourselves to present conditions. As regards the climate, which is entirely determined by solar action, the surface of the world at all times is the scene of all sorts of climatic conditions. At the Poles, where the sunbeam least penetrates, since even at midsummer the sun but swings round the horizon, perpetual frost practically prevails, and the land is buried beneath accumulated ice, born of unmelting snows. At the Tropics contrary conditions obtain, since the sun rises about due east all the year round, soars perpendicularly to the zenith, and sets about due west with monotonous regularity. In the Temperate regions wherein we dwell, the swing of the earth's axis as it rolls round the sun causes an alternation of warmer and colder seasons by exposing its surface to longer or shorter periods of sunshine, according to the inclination of the axis in question. The globe, in fact, is like a top spinning aslant, and as this slant is alternately towards and away from the sun the top half and bottom half receive alternately more sunshine or less, according as the season is summer or winter. These may sound like commonplaces, but they serve to illustrate our theme. All these revolutions, oscillations, and alternations of sunshine exposure are cosmically exactly reproduced every year, with practically no change, and the question, therefore, arises, "Why do our annual meteorological records display such diversity?" One year we have an abnormally heavy rainfall, almost constantly cloudy skies, and comparatively little bright sunshine, accompanied by persistent coolness, or even cold, while the very next year, such as we have recently experienced, may yield a record of sunshine, heat, and drought hardly equalled in man's memory. Week follows week of cloudless skies, and month after month succeeds on similar lines, until our normally green fields are drained both of surface and underground moisture to such an extent that they are brown and arid almost as the sandy deserts of the parching East. Trees, which normally should be retaining their foliage fresh and green, are perforce shedding it a month or six weeks in advance, the lack of moisture at the roots, coupled with scorching heat, having practically burnt it up. All succulent vegetables have suffered terribly, creating an absolute dearth in many places, though succulent plants of the sedum, mesembryanthemum, and other drought-resisting or drought-loving plants, have been entirely in their element. The damp and shade-loving fern tribe has been terribly handicapped, and since the abnormal heat and drought induced by the ever-persistent sunbeams have not spared our Western counties and coasts, where an ample rainfall is the rule, the havoc has been great indeed, particularly among the youngsters. It has indeed been a drastic struggle involving the survival of the fittest under extreme conditions which are rarely experienced in this fairly equable climate of ours. Shallow-rooting plants, with large areas of foliage, and consequent great demand for water to make up for extra transpiration, have had no chance, all the soil within their reach having been baked and deprived of even that small modicum of moisture which suffices to keep them, at any rate, alive, though growth be checked, or entirely stayed, and if any have survived that survival has been due to artificial irrigation, which, on a sufficiently liberal scale, has been often quite impracticable. The sunbeam, in short, has distributed its favours very unequally; the corn-growing farmer had his crops precociously ripened, but otherwise unharmed; though favoured with ideal weather for harvesting, the cattle owner and dairymen have suffered terribly by the check on grass growth, which forms the staple food of their stock, a boon in one direction, and a bane in the other.

Mr. J. T. Barker is well known in the broad shire of York as head gardener to W. P. Burkinshaw, Esq., West Hill, Hessle. Among horticulturists at large Mr. Barker's reputation is chiefly in connection with orchids, his charge at West Hill including a large and comprehensive collection of these handsome and increasingly popular plants. Of choice plants and rare varieties there are many, so that the collection is well above the ordinary in point of merit, as well as extent. Mr. Barker commenced his horticultural career at Hassobury, Bishops Stortford, and proceeded from thence to Harewood House, Leeds, where he laid the foundation of his wide experience. After a stay as journeyman at Harefield Grove, Rickmansworth, he served as plant foreman at Cyfarthfa Castle, Merthyr Tydvil, a place famous for good gardening. His next appointment was at Tyntesfield, Bristol, another famous garden; his next move was to Hoar Cross, Burton-on-Trent, where he acted as foreman for over four years, leaving this establishment to take charge of the gardens at Burton Closes, Bakewell. Here another four years were spent, and then a couple of years in the Isle of Wight. With this experience in various parts of the country Mr. Barker was well fitted for the position he occupies, and which he has filled for nearly seventeen years, to his own great credit, and the satisfaction of his employer.

Postponement of R.H.S. Lecture.—We are informed by the Rev. W. Wilks that Mr. Henry Hooper's lecture on "Science and Practice—Their Relation in Horticulture," which was to have been delivered on Tuesday next, the 10th inst., has been postponed.

"**The Botanical Magazine.**"—The issue of this venerable publication for the current month contains coloured illustrations of Lissiochilus stylites, Aphelandra fascinator, Spiræa Wilsoni, Rhododendron ambiguum, and Buddleia officinalis. The first-named is a handsome species, introduced from Southern Nigeria, attaining a height ranging from three to five feet, and bearing spikes of rose-purple flowers. Aphelandra fascinator is a handsome species bearing brilliant scarlet flowers, and has been in cultivation many years and is much appreciated where plants from tropical regions are grown. Spiræa Wilsoni is a shrubby species, introduced from Central China, and is closely allied to S. Henryi and S. Veitchi, which also are natives of China. The flowers are pure white, and freely produced. Rhododendron ambiguum is a distinct species with yellow flowers, and is a valuable addition to the small group of yellow-flowered species and varieties. It was introduced from Western China by Mr. E. H. Wilson, when collecting for Messrs. J. Veitch and Sons, and has the promise of proving quite hardy. Buddleia officinalis was originally discovered by Dr. Piasezki in the provinces of Shensi and Kansu in Northern China, and has also been found by Mr. A. Henry in the province of Hupeh in Central China. It has since been met with in the Yang-tze Valley by Mr. E. H. Wilson when collecting on behalf of the Arnold Arboretum and to him belongs the honour of introducing it to cultivation. The flowers are pale lilac and borne in medium-sized thyrses, and with reference to the usefulness of the species it is stated that it "promises to be a useful winter-flowering plant for greenhouse decoration, a class to which additions are always welcome." It is thought that it may prove hardy in the South-west of England.

"**Gardeners' Magazine" Fruit Number.**—In view of the commencement of the planting season, we shall devote our next issue (October 14) chiefly to fruits and fruit culture. The subjects that will be dealt with will include the best apples for bush culture, the newer culinary apples, successful fig culture, successional peaches for open walls, some good late dessert pears, culinary plums, and fruit trees in the flower garden. We shall also give a full report of the Royal Horticultural Society's exhibition of British-grown fruit. The number will, as usual, be freely illustrated, and the illustrations will include several of the more noteworthy contributions to the fruit show.

Notification of American Gooseberry Mildew. — The "Gazette" of September 29 contains an Order by the Board of Agriculture and Fisheries dealing with the disease affecting gooseberry and currant bushes, known as American gooseberry mildew. The Order, which came into operation on the 30th ult., and may be cited as the American Gooseberry Mildew Order, 1911, provides that the occupier of any premises on which there is a bush which is, or appears to be, diseased shall forthwith notify the fact to the Board of Agriculture or to the local authority for the district, under the Diseases of Animals Act, 1894. The local authority, on receiving such notice, shall take such steps as may be necessary to determine in what gardens the disease exists, and shall cause notice of such determination to be served on the occupier of each of such gardens, which shall thereupon become "infected premises." Other provisions deal with the action to be taken by the local authority, after preliminary investigation, for the prevention of the spread of the disease. Every person who fails to comply with the provisions of the Order is liable, on conviction, to a penalty not exceeding £10 on each offence. Copies of this Order, which is to be carried into effect by the local authorities, who have power to appoint such inspectors or other officers for the purpose as may be necessary, can be obtained on application to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, S.W.

Salvia Glory of Zurich at Gunnersbury House.—We have in the course of the past summer briefly referred to two or three of the many features of interest in the gardens of Gunnersbury House, the well-known residence of Leopold de Rothschild, Esq., notably the fine collection of water lilies and the beautiful grouping of heliotropiums. No mention has, however, been made of the glorious colour effects that Mr. J. Hudson produced during the latter part of the summer, chiefly with the aid of that fine form of Salvia splendens known as Glory of Zurich. This salvia is remarkable for its neat habit and the profusion with which it produces its fine spikes of brilliant scarlet flowers, and Mr. Hudson was one of the first of the English cultivators to fully recognise its merits, and to grow it on a comparatively large scale. For several years past it has been freely utilised in the furnishing of the wondrous roof garden at Gunnersbury House, and in beautifying the terrace, and, it should be mentioned, with a full measure of success. This year the salvia has been employed in the decoration of the bridge at the foot of the lake in the lower part of the grounds, and nowhere does it appear to greater advantage. Planted in boxes on the top of the wall on either side of the bridge, the plants have made a free, yet compact growth, and, rising from the broad belt of closely-set foliage, there have been during the latter part of the summer and until the present time, many thousands of flower spikes. When we saw the bridge a week ago they formed a belt of flowers about three feet in width and produced a colour effect of great beauty. It being desired to have the plants at their best late in summer, the earlier flower spikes were removed.

Examination in Gardening.—The British Gardeners' Association held an examination in horticulture for professional gardeners on Wednesday, April 26, and from the report now published we learn that twenty-nine candidates entered for the examination, and that twenty-eight sat in as many different centres in England and Wales. There was one candidate in Scotland and none in Ireland. Nine were placed in the first class, ten in the second, and eight in the third. One candidate failed to obtain a place. The candidates who were successful in obtaining a place in the first class, with the number of their marks, were as follows: Mr. Harry Chandler, Great Bookham, 249; Mr. Charles Elsley, Hayward's Heath, 245; Mr. Matthew Ward, Hexham, 230; Mr. Charles Lewis, Penarth, 216; Mr. George Henry Payne, Leicester, 212; Mr. Gerald Butcher, Kew, 209; Mr. Ernest Smallman, Birmingham, 207; Mr. George Rimmer, Rochdale, 205; Mr. Arnold Duley, Cardiff, 201. Mr. H. Chandler, having obtained the highest number of marks, has been awarded the British Gardeners' Association's gold medal. The other candidates who obtained a place will receive a special examination certificate.

Orchards in the Teme Valley.—In an interesting article on hops and fruit in the West of England, the special correspondent of "The Times" makes the following reference to the orchards in the Teme Valley: "Worcestershire is one of the six counties containing more than 20,000 acres of land under fruit. The great part of this area is occupied by grass orchards growing cider fruit, though in more than any other county west of Kent do wo find new plantations of highly-farmed table fruit occurring in the Teme Valley, as well as about Evesham and Droitwich. In Kent 40 per cent. of the fruit is grown on tilled land and 60 per cent. in grass orchards. Worcestershire has 23 per cent. of its fruit on tilled land, but Hereford only 13 per cent., Gloucestershire and Devon about the same, while practically the whole area of the Somerset fruit land is under grass. On the whole, fruit trees in the Teme Valley, with the rich soil and the softer atmosphere, tend to make more vigorous growth than they do in Kent. In consequence they do not come into bearing quite so early, and require a little different system of management and pruning in order to make them fruitful, their tendency being to run to wood rather than to fruit. In the Teme Valley the more recently planted land generally carries apples, with a smaller proportion of plums than in other districts where railway facilities are better; cherries are not so much grown, and pears in England rarely form a very profitable market crop. Perry pears are, however, a great feature of the district, being confined to the

Worcester, Hereford, and Gloucester area, and occurring rarely in the other cider-making counties of Devon and Somerset. We heard, however, of very little planting of vintage fruit; in the old orchards worn-out trees may be replaced from time to time by new ones, but in general the tendency is for the cider fruit to give place to table fruit. The pear trees in particular are generally very old; indeed, on our way to Tenbury we passed what is reputed to be the largest pear tree in Great Britain, still in full vigour and yielding an enormous weight of fruit in a favourable season."

Trials of Potato Diggers and Sorters. The trials of potato diggers by the Royal Agricultural Society were carried out at Littleworth, near Spalding, in accordance with the arrangements to which we directed attention in a recent issue. The trials were carried out under favourable conditions, and the results generally were regarded as of a most satisfactory character. Fourteen machines were entered for the trials of potato diggers, and the judges awarded the first prize of £20 to Martin's Cultivator Company, Lim., Stamford, and the second prize of £10 to Messrs. Blackstone and Co., Lim., Stamford. In competition for the prizes for the potato-sorting machines six were entered. About two tons of potatoes were dealt with by each machine, and in most cases the work was satisfactorily performed. The first prize of £10 was awarded to Messrs. Cooch and Son, of Northampton, and the second prize of £5 to Mr. Walter Ness, of King's Kettle, Fife.

September Sunshine.—Notwithstanding the changeable weather which prevailed during the second half of the past month, the record of bright sunshine was very large. At Westminster the duration of bright sunshine aggregated 215 hours, or 98 hours in excess of the average, and 21 hours in excess of the highest record for September since 1883, when regular observations commenced. Since the year mentioned the only Septembers in which the duration exceeded 150 hours were those of 1895, 1898, and 1906, the respective amounts being 194 hours, 172 hours, and 158 hours. The total record of bright sunshine for June, July, August, and September has surpassed all previous records for corresponding periods. At Westminster the total duration was 989 hours, giving a daily mean of rather more than eight hours. The average for the four months mentioned is 633 hours, or a daily mean of about 5½ hours. There were only three sunless days, as compared with an average for the past 32 years of nine days, in which bright sunshine was not recorded.

Pentstemons from Hawick.—At the present time we have on our table a vase of pentstemons, which is equally remarkable for its interest and attractiveness. The splendidly developed spikes of flowers with which the vase is filled were received from John Forbes (Hawick), Lim., and include many of the finest varieties that have been introduced to cultivation, and they show that this well-known firm continues to devote a full share of attention to pentstemons, for which they have long been famous. Conspicuous among the many varieties that are now before us are the brilliant scarlet Professor Pozzi, Crimson Gem, and Sandringham; the rich pink and white John Ruthven, bright rose-red Garth and Lady Noble; the charming picotee-edged Schwesser Sophie, which may be described as one of the finest of the light varieties; the deep crimson J. A. Clyde and John Decan, the latter remarkable for its pure white throat; the orange-red Marchioness of Linlithgow and Crown Princess of Sweden, and the deep purple Adjutant Cincent and Colonel Seeley. Although we have linked together the varieties that are closely allied in colour, it should be understood that they are all perfectly distinct. The free branching of the spikes that is characteristic of the Hawick varieties adds immensely to their effectiveness both in the garden and decorative arrangements.

A Bacterial Disease of the Cherry.—In the course of the proceedings of the British Association Mr. F. T. Brooks called attention to the fact that Aderhold and Ruhland had recently proved that a disease of cherry trees in Germany was caused by a bacterium which they named Bacillus spongiosus. Affected trees exhibit symptoms similar to those of pear trees attacked by "pear blight," which was also a bacterial disease. Young trees were attacked, shoots and entire trees being sometimes killed. Profuse gumming occurred in the affected parts. Aderhold and Ruhland isolated Bacillus spongiosus from the masses of gum and grew this organism in pure culture. Inoculation experiments clearly showed that this bacterium was the cause of the disease. But this organism was not the only cause of gumming, for certain injurious fungi were known to induce similar exudations from cherry trees.

EVOLUTION AND POLLINATION OF SWEET PEAS.

Mr. Alvin C. Beal, of the Cornell University, Ithaca, New York, has had the care of the sweet pea trials conducted by the National Sweet Pea Society of America, and at Philadelphia in June last, at the society's convention, he read the following paper:

During the first 100 years of the history of the sweet pea only three varieties or colours were known; namely, purple with blue wings, pale red with white wings (Painted Lady), and white. The black and scarlet appeared in the last years of the eighteenth century. It is quite probable that the scarlet was far from what we conceive a scarlet sweet pea should be to-day. In Martyn's edition of "Miller's Gardeners' Dictionary," 1807, we find the white, the Old Painted Lady, the New Painted Lady, the latter with a rose-coloured standard and pale rose wings, Old Purple, and a variety having a violet keel and wings and purple standard. Sayers describes the scarlet sweet pea as Lathyrus flore rosea, while the Painted Lady is described as "fleshed" colour. From this we may conclude that the New Painted Lady, a rose-coloured variety, was sometimes called scarlet.

Improvement in Colour.

The first of the striped varieties was offered in 1837, and since that date this group has been augmented until the classification now includes striped and flaked (red and rose, purple and blue). This classification, however, does not express the real range of colour in this group, for we have crimson stripes—for instance, America; red and rose stripes on white—Aurora; red and rose stripes on primrose—Jessie Cuthbertson; mauve stripes—Gaiety; blue stripes—Prince Olaf and Hester; maroon-flaked, like Senator. The American growers have introduced the majority of the best varieties of this group, among which are America, Aurora, Columbia, Daybreak, Gray Friar, Juanita, Pink Friar, Ramona, and Wawona. Many of these are now procurable in the waved form.

The Blues and Pinks.

The variety Blue Edged, the probable forerunner of the picotee forms, appeared in 1860. This was a white variety with a well-defined blue edge, a probable hybrid between L. magellanicus and a white variety of L. odoratus. The variety, at all events, was the first to exhibit a distinct blue colour among sweet peas. Later it was known as Blue Hybrid, under which name it won an award from the Royal Horticultural Society. Sutton and Sons sent out Butterfly in 1878, which somewhat resembled Blue Edged. The so-called blues that followed were Invincible Blue, Madame Carnot or Imperial Blue, and Captain of the Blues, all of which had considerable red in the standard. It was not until 1899 that a good blue, in Navy Blue (Lord Nelson) appeared.

The first of the soft pink varieties was Crown Princess of Prussia, 1868-9. Isa Eckford, Peach Blossom, and Lovely are the improved varieties of this colour.

Improvement in Form.

The efforts of the breeders of sweet peas have not all been directed toward the development of new shades of colour. The form of the flower has also received attention. The earliest representations of sweet pea flowers show a loose, irregular bloom, with the edges of the standard turned back; that is, reflexed. Often, if not always, the standard had the notch in the apex and frequently in the margin. The standard, which is the principal part of the flower, has been improved in substance and the notches have been eliminated. The old type had a narrow base, and with the improvement noted has come a filling out of the lower edges of the standard so that the outline approaches a circle.

In their efforts to secure varieties of the best expanded or open form, many beautiful hooded varieties were originated. While this form was condemned as inartistic by many sweet pea specialists, it nevertheless secured a permanent place. Prima Donna, Lovely, and Countess of Radnor are of this form.

The Spencer Type.

When many had reached the conclusion that no further advances in either size or form were to be expected, and that the efforts of future breeders would be directed toward securing new colours and more flowers per stem, Nature demonstrated that she had other surprises in store.

In 1901 the Countess Spencer variety was exhibited, and caused quite a sensation. The National Sweet Pea Society of Great Britain awarded it the highest honours. This variety was distinct from all preceding introductions because the standard and wings were waved. The flowers were large, and borne in fours on stout stems. It was introduced in 1904.

The parentage of this variety has been given as Lovely x Triumph (1898) x Prima Donna, 1899. However, there appeared in 1905 a variety named Gladys Unwin, which was the same colour, but smaller and less waved than Countess Spencer, and which was a selection from Prima Donna without known crossing being effected. These varieties, however, were forerunners of the new type which revolutionised sweet pea culture in England, and has revived and quickened the interest in America.

Pollination.

We have previously noted that the pistil and stamens are enclosed in the keel formed by the partial coalescing of the two lower petals. A slight pressure upon the base of the keel will cause the pistil to appear suddenly in the tip of the keel. The stigmatic surface is usually covered with pollen, and at the same time the stamens appear to view. If the pressure is released, these organs disappear as suddenly from view.

Process of Self-fertilisation.

Those who are looking for flower adaptations for the promotion of cross-fertilisation would say at once that here we have a mechanism which is operated by the weight of the bee alighting on the keel, and the pistil and stamens rise up, striking it upon the body, receiving and giving pollen. Thus, as the insect visits flower after flower, natural cross-fertilisation is carried on.

This, however, is not the case. In the first place, if we examine flowers in the bud stage, we find the pollen ripe. The position and condition of the stigma changes, for before the maturation of the pollen the stigma is below the anthers. A day or two later the stigma has risen to a position among the anthers and is viscid enough to hold the pollen grains.

In another day or two it has grown beyond the anthers. Self-fertilisation has taken place, and the development of the legume begun. This process has taken place before the flower is fully open. Some time later the pistil is pushed out of the protecting keel by the developing pod.

Not Dependent on the Bees.

Such is the normal fertilisation of sweet peas, as observed upon examination of the flowers. Attention has been called to the fact that the sweet pea stood practically still for 150 years, and the question is asked how this can be reconciled with natural cross-fertilisation.

During the writer's experience in the field last season for three months, studying varieties and recording observations, not a single instance occurred of a bee alighting upon the keel of the flower, nor were any observed crawling between the wings. All the bees observed visiting the flowers alighted on the outside of the wings, and in practically every case thrust the proboscis down between the right wing and the standard. In this connection it may be mentioned that the bees did not show a preference for any particular colour, but flew from row to row and from colour-section to colour-section.

T. H. Dipnall has observed that bees attack sweet pea flowers. The bee, a yellow and white banded species, alighted on the calyx crawled around to a certain position, and cut a hole through the calyx so that it could thrust its proboscis through and suck the nectar at the base of the pod. The reason is not clear why the insect prefers one side of the flower, since the structure is similar on each side.

It is to be remembered in this discussion that sweet peas grown under glass in winter are not visited by bees, but every flower in sunny weather will set seed if the blooms are not kept cut.

Trouble in Fixing Varieties.

Since the introduction of the waved type there has been much discussion about the difficulty in fixing varieties and the reasons for it. Some growers, having secured what was to all indications a fixed stock, discovered after sending it out that it was not fixed. Some growers thought it only occurred when the novelty was sent to California to work up a large stock of seed, or after it had passed into the hands of the Californian growers. One of the theories advanced to explain this was that an insect in California was responsible for some cross-pollination of flowers. In our own trials this past season no differences were observed between English or American grown stock, since we had seeds of novelties direct from the originators and our varieties were from the introducers. Others say that bees visit the flowers, and they believe that crossing takes place in the waved type, which, it is maintained, does not produce normal flowers, in that the pistil sometimes projects beyond the keel.

Poor Setting of Seed.

It appears that, if this view is correct, the poor seeding of the waved type would not occur, or at least that the worse the fault of the flowers the greater the crop of seed. Thus the varieties which seeded freely would become cheap and drive out the others. The writer thinks that the results obtained by the seed growers contradict the theory. It appears that the poor setting of seed may be due to the fact that the pistil may grow out beyond the anthers before the latter are mature, and thus fertilisation be prevented by irregular development of the parts. Otherwise the pollen may be impotent in some varieties, but this does not occur so far as the writer has studied the reports of the sweet pea breeders. The writer did not observe any pistils showing the defect mentioned, but, as our season was extremely dry, our plants did not make an exceptional growth which would be likely to express itself in abnormal flowers. However, it was observed that some varieties seeded more freely than others. We have planted most of the varieties this year from seeds saved in 1910, and, knowing those which were fixed last year as well as those with rogues of certain colours, we think that some light may come upon this matter of cross-fertilisation, if any, in the sweet pea.

HIGHER EDUCATION OF GARDENERS.

Quite recently I have come to reside in the North of England, where I find the education of gardeners is receiving the interest of public men, and a scheme for their advancement is being formulated. This subject of education embraces many practical means whereby a young gardener may procure knowledge more readily; amongst them is travel, not necessarily abroad, but in this part of the world—the British Isles. I have considered various plans which might more or less successfully be advocated, and foremost is the formation of a "National Guild of Gardeners," or "The Institute of British Gardeners," or "The Horticultural Labour Exchange." These three titles have been put forth by three great enthusiasts in the horticultural world, either of which would embody a step in the right direction for the ultimate well-being of the fraternity.

I have been in communication with the Rev. J. Bernard Hall, the secretary of the North of England Horticultural Society, a gentleman who has the welfare of gardeners and gardening at heart, and who would be pleased to receive any suggestions from gardeners and horticulturists of all ranks with a view to the formation of a National Society; or names for membership, or any offers of assistance to formulate such a scheme.

Such an institution should include quite young gardeners, nursery employees, under and head gardeners, nurserymen, and, as hon. members, the wealthy friends of gardening. A nominal annual fee would be demanded from young men, and an annual subscription or a good donation from others to form the nucleus of a fund.

The object to comprise:

(a) A method whereby a young or under-gardener might improve his knowledge by interchange of work with a fellow member, either in a nursery or a private establishment, viz., a young man, after spending 1½ years or thereabouts in a Southern county, might exchange places with another member in the Eastern, Midland, or Northern counties.

In this matter no better opportunity could be afforded to gain an insight into different methods of forcing, floral work, hardy fruit cultivation, or any of the numerous branches appertaining to the profession.

(b) Arrange for an annual conference in a different large centre annually.

(c) If sufficiently supported, to establish branches in all large centres, or at least a branch in each county.

(d) Form a circulating library.

(e) Arrange for lectures, correspondence classes, facilities for the preparation for examinations in order to qualify for important posts; these and other suggestions may be arranged for, and a staff appointed to organise and carry to a successful issue, such a scheme as herewith set forth, would tend to promote horticulture generally to a higher level.

John Smith,

County Council Lecturer, and Instructor in Horticulture to the Durham County Council.

SCHOOL TEACHERS' EXAMINATION IN GARDENING.

In looking through some back numbers of your magazine this week, I came across an article in your issue of June 17 by Mr. G. H. Hollingworth, criticising the questions set at the above examination of the Royal Horticultural Society last April. I read his criticisms of the questions set by this body with very much interest, especially as I was a candidate at that examination. Mr. Hollingworth is evidently very courageous in attacking the form of questions set by a society established in 1804! I must at once say I entirely agree with every word of his article.

The examination is supposed to be held for school teachers, but I fail to find in a single question anything which an ordinary amateur gardener could not answer, even if he had never seen a class of boys in his life.

How this examination can be a test of capacity to teach school gardening, I do not know. Gardening, as taken in primary schools to-day, is a very different thing from cottage gardening. You cannot satisfy his Majesty's Inspector that the subject is properly taught unless you fulfil, in some measure, the "suggestions of the Board of Education for the teaching of gardening."

I have already stated that any amateur gardener can pass this R.H.S. examination if he can write English correctly, but few amateur gardeners could satisfy the demands of the Government Inspector that they had taught the subject satisfactorily.

Why, to-day, teachers must not only teach gardening, so that boys can appreciate it as a manual process of hand and eye training, but the intellectual and educational value must be apparent in the schoolroom. In what part of this examination (which of the questions) seeks to discover whether the candidate is alive to this part of the boys' training?

Although the Board of Education's "Suggestions" are valuable, I do not know of any books yet published which give assistance to teachers in the educational side of the question; but, in the county in which I teach, this deficiency is made up by the eminently valuable suggestions given by our horticultural expert, and, also, the Director of Education, both of whom recognise and appreciate the relation of the garden to our other school work.

I do not know whether any county experts who organise school gardening are consulted by the Royal Horticultural Society respecting the questions set in this examination, but it does not appear so, and if they were, then perhaps the R.H.S. school teachers' examination questions would be drawn up on more educational and less bookish lines. Until something of this kind is done, I fear Mr. Hollingworth's hope, that after passing the examination teachers will be better teachers of gardening, will not be realised.

R. H. S. Qualified Teacher.

Calceolaria Burbidgei. — This hybrid calceolaria, which is so much used for summer bedding in the shape of large plants, is also equally valuable for the embellishment of the greenhouse during the autumn and winter months. For this purpose it is best grown out of doors and given much the same summer treatment as a chrysanthemum.—W. T.

Shrubby Veronicas.—In the West of England and other favoured spots, the different shrubby veronicas are particularly valuable as outdoor shrubs, while in other parts they are equally serviceable for the decoration of the greenhouse. There is now a long list of varieties in which the blossoms vary in colour from white to deep crimson and purple, while the habit of the plants is compact, so that they can be grown into neat little bushes that will flower well.—W. T.

TREES AND SHRUBS WITH ORNAMENTAL FOLIAGE.

When planting deciduous trees and shrubs, it is well to bear in mind those kinds conspicuous on account of their brilliantly-coloured or otherwise ornamental foliage, for many of these contribute as largely to the beauty and character of the garden during the late summer and autumn as do the numerous flowering subjects in the spring. The recent continuous sunshine has contributed largely to the brilliant colouring of some of our most handsome trees, and at the time of writing many have assumed a splendour only equalled in exceptional seasons.

Among these charming subjects nothing is more rich and effective in its colouring than Berberis Thunbergi, which has assumed a most vivid crimson. There are numerous beds of this lovely berberis in the gardens here, but the most attractive of all is one huge mass against a background of Forsythia suspensa, and being in a conspicuous position this is greatly admired. Berberis atropurpureum is another kind with ornamental foliage. Liquidambar styraciflua is now at its best, its foliage being a lovely purple hue, and several tall pyramidal specimens in a shrubbery produce a very fine effect. This tree likes a rich loamy soil, and succeeds well in a rather moist situation. Aralia chinensis (Dimorphanthus) is a striking object with its bronze-tinted foliage, and needs a sunny, sheltered aspect to colour well. Castanea sativa is a handsome tree, as its glaucous green foliage sets off the ornamental golden fruit to advantage.

The foliage of most of the flowering cherries is now especially showy, many being a pleasing bronze shade. Cratægus crus-galli is very fine, being heavily laden with crimson berries, and the common hawthorn has rarely presented such a picturesque appearance, with its crimson crop. Rhus cotinus and R. toxicodendron are both a brilliant crimson, and so form especially striking objects. The latter makes a good climber, and is especially suitable for training on a low wall or balustrade Quercus coccinea, the Scarlet Oak, and Q. concordia, a yellow foliaged kind, are both handsome and effective trees. Euonymus europæus is a lovely colour at the present time, and its fruits are almost as showy as the foliage. Paliurus aculeatus is very picturesque, its yellow fruit showing conspicuously against the green leaves, which also turn a lovely yellow shade.

Populus canadensis aurea and Prunus Pissardi retain their colour throughout the season, and are especially effective for grouping. Hamamelis arborea and Viburnum plicatum have assumed a beautiful crimson hue, the foliage of the latter being almost as effective as are its flowers in June. The common beech is very handsome in the autumn, and is then almost a rival to the picturesque copper and purple beeches. Another effective shrub is the golden Cut-leaved Elder (Sambucus racemosa serratifolia foliis aureis), and planted in masses it is especially ornamental. Rosa rubrifolia is well adapted for planting in the wild garden. Cornus alba Spathi is a finely variegated dogwood, and planted in beds associated with Prunus Pissardi is most effective.

Corylus avellana purpurea is very ornamental for a prominent place in the shrubbery, and looks well used in conjunction with variegated foliaged subjects like Acer negundo variegata. Probably nothing surpasses the Japanese maples among deciduous shrubs, in point of colour.

J. Gardner.

THREE GOOD NEW SWEET PEAS.

There are several sweet peas that have done well in the terrible season just over, and many new varieties that have attracted considerable attention by reason of their fine form and colour. The following three are not here referred to as standing head and shoulders above all other new sorts, but attention is drawn to them because they possess high merit and distinctness, and are thoroughly well worthy of cultivation.

Afterglow, one of the novelties from Mr. Robert Bolton, Warton, Carnforth, met with general approval on the occasion of the National Sweet Pea Show in July last. It was well shown in Mr. Bolton's stand, and one of his baskets is herewith illustrated. The variety has good form, size, and excellent stems, and it presents a novel and pleasing shade of colour that is best described as deep mauve-purple. There is such a softness of shade and such a beautiful sheen over the blooms that almost everyone admires the variety; certainly it did not lack admirers at the great London show.

Bertha Massey is a charming sweet pea, and its exquisite shade of bright mauve-lilac has already made it a first favourite in the estimation of ladies. As an exhibition flower, however, it stands out well, and it is especially valuable in, say, a class of twelve varieties, because of its attractive colouring, and the way in which it lights up deeper-hued sorts. Messrs. S. Bide and Sons, Farnham, are the raisers of this fine waved novelty, but the bunch illustrated was one exhibited splendidly by Mr. Thomas Stevenson at the National Show.

Thomas Stevenson, raised by Mr. Robert Holmes, of Norwich, bears the name of our able contributor, Mr. Thomas Stevenson, head gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone. Mr. Stevenson's knowledge of sweet peas is particularly wide, and his success as an exhibitor is so well known that when we say he wished this variety to bear his name, it may be taken for granted that in colour and size and form, this sweet pea stands in the first rank. The variety was shown well this year, and one of Mr. Stevenson's bunches of it is herewith illustrated. The colour of Thomas Stevenson is variously described as orange-scarlet and orange-salmon, and these descriptions convey a very good idea of the shade seen in this brilliant variety.

SWEET PEA BERTHA MASSEY.

A charming variety with large mauve-lilac flowers of great beauty; raised by Messrs. S. Bide and Sons, Farnham.

FRITILLARIA CONTORTA.

Lovers of bulbs in the alpine garden are not generally aware of the existence of a singular, yet rather pretty white fritillaria, to all appearance one of the Meleagris section, and probably only a variety of that plant. It is not generally mentioned, but is, I observe, described in the last supplement to Mr. Nicholson's "Dictionary of Gardening," where, I notice, it is said to have been introduced in 1886, which is, I am pretty confident, an error, as I had seen it before that time. It is there said to be of unknown origin, and I have no record of its first appearance. But this matters little, and it is sufficient to say that it is very distinct in the appearance of its flowers from the ordinary bell-shaped blooms of the white varieties of F. Meleagris. The flowers are more tubular, and the segments are united, not separate, this being, to a great extent, the cause of the shape of the flower. There is also a slight twist in the segments, this giving the plant the name of contorta. The bells are very wax-like in their aspect, and the plant generally attracts notice when seen, even by one not too well versed in flowers of its kind. The species is one that should, in the course of the season, be planted by those who appreciate the charms of the fritillarias.

S. A.

AUTUMN SOWING OF SWEET PEAS.

The demand for sweet peas is now so great that every advantage must be taken not only to secure flowers of good quality, but also to obtain them as early as possible. Consequently, the autumn sowing of sweet peas is becoming more popular each season, and whether the cultivator grows for the market or for home decoration, or purely for exhibition purposes, he cannot afford to ignore this very easy means of obtaining supplies of blooms that are both early and good.

Sowing in the Open.

On fairly light, well-drained soil, and in districts where the frosts are not too severe, the seed may be sown in the open, but I would not advise this except for market or ordinary cutting purposes. Even in favourable localities the risk is too great for sowing the seed of high-priced and newer exhibition varieties out of doors. There is not only a risk of losing the plants by frosts and cold winds, but when large quantities are sown in the open the losses from birds, mice, and wire-worm are pretty considerable. It will therefore not be wise to sow other than the cheaper sweet peas in this way, except when so small a number is grown that it is a quite easy matter to protect them. The best date for sowing in the open ground is about the second week in October or even the third or last week in a season such as this, when the soil must still be in a very warm condition.

The greatest mistakes with autumn sowing is committing the seed to the ground too early. Fairly strong, sappy plants often suffer to a greater extent than do nice little seedlings ranging from two to three inches high. If they are about the height mentioned by the end of November, they will stand a far better chance of passing through the winter successfully than would those more advanced in growth.

The ground for autumn sowing should have been prepared some little time beforehand by trenching, and not too liberally manured near the surface; but plenty of good rich manure should be incorporated with the lower spit of soil, which the roots will reach towards the end of the spring and fully utilise in promoting a vigorous growth and the continuous production of flowers. Before sowing the surface of the ground should be well broken, so that the seed may be sown in very fine soil. This is quite essential, especially if heavy; the more it is broken the less harbour will there be for slugs.

I prefer to sow in narrow drills, usually two drills one foot apart to make a row. The depth of sowing should vary according to the character of the soil, the rule being the lighter the soil the deeper the drills. In the case of the cheap varieties the seed should be sown rather thickly to allow for losses, it being quite an easy matter to thin in the spring if the plants are too crowded. Soot I find is one of the best preventives of damage by birds and slugs, and as soon as the plants appear above the ground a slight dusting should be given, repeating it as often during the winter as may be necessary.

A protection in the form of a few small bushy stakes will sometimes be useful to sweet peas in their earlier stages of growth, especially if placed a few inches away from the rows on the windy side. Apart from this there is very little to be done to them during the winter, but occasionally the spaces between the rows may be hoed if the state of the weather permits, but care must be taken not to use the hoe during what one might term the catchy weather in the spring. I have often seen peas badly frozen where the ground has been recently loosened, while others have come through quite well.

Sowing in Pots under Glass.

As an alternative to sowing in the open ground, sowing in pots and wintering them in unheated frames may be tried, and this I consider the most economical method, and in nine seasons out of ten it will be found the most satisfactory. The best time of sowing is about the same as in the open ground, but not later. I find a few days makes a very great difference in the constitution of the plants, and on no consideration would I advise sowing for wintering in pots after the third week in October. If the sowing cannot be made until after this period, I consider it preferable to wait till the early spring.

For extra good results and for exhibition purposes single pots may be used, but when five or six seeds are sown in each 48-sized pot really excellent results will be obtained. Fairly light soil, not made too firm, answers very well, and the young plants can be shaken out from this quite easily, and it is necessary, as by far the best results are obtained when the young plants are carefully separated and planted singly. When grown for market purposes this practice is said not to pay so well as when planted pretty thickly, thereby obtaining a heavy crop of flowers during the first week or two of their being in bloom.

After sowing the seed pots should be placed in an unheated frame, keeping the lights on till germination takes place, when they should be removed entirely on all favourable occasions. In fact, the lights should only be put on during wet or very frosty weather. About the end of November or early in December the pots should be plunged in coal ashes or other material, allowing a little space between them. This will allow the air to circulate between the seedlings, and do away with the necessity of water till quite late in the spring.

It may be necessary to place a few very small twigs among the plants to keep them upright, but these ought not to be wanted till the end of February when the growth will be active. Precautions must be taken against the depredations of birds and mice, also a covering of mats may be necessary in the event of severe frost, for, although a little frost will do them no material injury, it is not wise to expose them to a severe one. They may as well be sown in the open ground if they are to be fully exposed to the wintry weather.

As mentioned earlier, the advantages of autumn sowing are many. In the first place, they come into bloom earlier in the South —here, quite by the end of May; secondly, the quality of the bloom is infinitely better; and, lastly, they go on blooming over a much longer season, and, as I have mentioned before, the plants do not seem so subject to attacks of the dreaded streak disease, as do the spring-grown plants.

The matter of varieties is quite a personal one, and what may be selected for sowing in the spring may well be sown in the autumn, and the seedsmen, I find, are doing their best to cope with the growing demand for seeds for autumn sowing. The past hot summer has been beneficial in some respects, and as regards its influence on sweet peas, all the seedsmen of my acquaintance have good stocks of new seed which they are already distributing to their customers.

Thomas Stevenson.

DAHLIAS TO PERFECTION.—A thorough guide to the successful culture of these popular flowers is "Dahlias and Their Cultivation," by J. B. Wroe, price 1s. net, by post 1s. 2d., bound in cloth 1s. 6d., by post, 1s. 8d., from W. H. and L. Collingridge, 148, Aldersgate Street, London

VERBENAS IN POTS.

Not often do we see verbenas in pots in private gardens, but I do not see why they should not be more common, because for the months of September and October they cannot be other than useful. With the protection of a cold frame from heavy rains the flower trusses are more pure in colour than when growing in the open exposed to heavy rains and soil splashings.

At Aldenham Mr. Beckett has a big batch of verbenas in 6in. pots, as well as many planted on a south border, where they have succeeded remarkably well. Those growing in pots were raised from cuttings struck in the autumn in the usual way; the stoutest plants selected were topped occasionally, and now they are furnished with a dozen or so handsome trusses, especially bright in colour. As the plants have enjoyed abundant space during growth they are not in any way "drawn," but are stocky and well furnished with foliage which enhances the effect of the blossoms above.

The following are some of the most conspicuous varieties. Amongst blues with a white eye Dana and Servilla are noteworthy. In the purple section Arluc, E. Madelaine, Mysole, and A. de Lorde are conspicuous. Miss Willmott is still the best pink; Magique, rosy-purple; Ophelie, deep rose; Jomini, Parega, and Cadol, scarlet, with white eye; Bettina, rosy-purple; Chloris, dark chocolate-red, with a small white eye, are all good. King of Scarlets is still the finest self of that hue. Mesange, rose, with white eye, is very pretty. Snowflake is white, though at times tipped with pink. Halesque is probably the best white, and Zampa bright red with white eye, while A. Blondin, rose with white eye, is very effective in a mass. E. Molyneux.

LACHENALIAS.

The lachenalias are amongst the hardiest of our indoor bulbous plants, and requiring very little artificial heat, can be successfully cultivated by almost every gardener. The flowers are quaint in colour, and, the foliage being attractively marked, the whole plant proves itself a great favourite wherever grown. Being very accommodating, it can be grown either in pots or baskets. The bulbs should be planted in August, or early in September. A compost which is rich and fairly porous is the best rooting medium for them. In pot culture put five or six bulbs in a five-inch pot, and stand the pots in a cold frame, where they may remain until the frosts commence, when they must be removed to a cool greenhouse and given a light position.

The most striking effect is obtained when they are cultivated in baskets. For this purpose the basket is well lined with rough portions of loam, over which a thin layer of the rooting soil is placed. The bulbs must be planted with the crowns looking outwards, and towards the bottom, and in a position to allow the growths to come through the meshes of the basket. When the planting is finished, and the soil has been well watered, place a slate over the top and stand the basket upside down on pots in a cold frame. When the growths have come through, and made some progress, the basket may be hung in its normal position in a cool greenhouse. The plants will in process of development cover both the sides and bottom of the baskets, and when in bloom a very pretty and pleasing effect is obtained. When growing freely the water supplies should be liberal.

NOTES FROM SCOTLAND.

Vegetable Crops and the Past Season.

The Gardeners' Magazine of September 23 (page 702) contains an interesting, though somewhat doleful, article by "H." upon the excessive heat and drought of the past summer, and the adverse influence exercised thereby upon certain crops, but more particularly those of vegetables. As a few notes by way of comparison between the district "H." had in mind when writing (though he does not tell us where it is) and South-West Scotland may be of interest, I will endeavour to take up a few of the main points mentioned by "H.", and show the great difference there has been, and which apparently still exists, between the two places and in the crops produced.

SWEET PEA THOMAS STEVENSON.

This is a fine orange-scarlet variety of great brilliance; raised by Mr. R. Holmes, of Norwich, and introduced by Robert Sydenham, Limited, of Birmingham.

Vegetable Marrows and Beans.

Both of these crops were specially referred to by "H." as having been much below the average of previous seasons. Here I may safely state that, taking a retrospect of a long series of years, I have never known either to have been so plentiful or of such excellent quality, which is attributed solely to the increased amount of heat and sunshine. The crops of marrows mentioned by "H." may possibly have been those under field culture, where the restricted root run would prove inadequate to sustain the plants, whereas here, heaps of manure and old hotbeds, that afford plenty of nutriment, and do not quickly part with moisture, were, following upon custom, utilised for the purpose.

Beans of all kinds produced crops far above the average, and so much was this the case that, although no more than the usual area of ground was occupied by the crop, great quantities of pods had of necessity to be gathered and destroyed to keep the plants in bearing. This refers to both dwarf and runner types: each commenced to bear much sooner than usual, and still continues to do so at the present date, September 25. Except in private establishments there is but little demand for these vegetables in Scotland, although the Broad, or Longpod type of bean finds considerable favour.

Winter Crops of Vegetables.

Cauliflowers, Brussels sprouts, and winter greens in general are mentioned by "H." as being very unsatisfactory. Here the promise could hardly be better. The first-named, which consists mainly of the Autumn Giant type, is now at its best, and plenty of close, massive heads are available. Breadths of these, planted as second crops (following early potatoes, peas, etc.) have done exceedingly well, and give the prospect of abundance for some time to come. The same remark applies to the broccoli family, which, if anything, is too robust to withstand frost, should the winter prove very severe. Brussels sprouts, kales, and savoys are equally satisfactory, having made strong growth.

That the drought of the past summer has been very trying to cultivators none can deny, and in this part, at the present time, the scarcity of water in wells, brooks, and streams is such that no one remembers a similar occurrence. The rainfall of the past four months approximates six inches, of which September, though scarcely run its course, will probably be accredited with the least of any.

The Rainfall and Planting.

In some respects cultivators in this district were favoured by having a short period of moist weather from the middle to the end of June, which enabled those having ground in readiness to get the autumn and winter crops of vegetables planted, and the plants, having thus a good start, seemed afterwards to revel in the heat with pleasing results.

The wearying occupation of applying water to vegetable crops by the ordinary means of can and barrow would be greatly lessened were more use made of the various instruments now upon the market for stirring the surface soil, a fact that has probably been impressed this season upon many, when the water supply has given out or has been so much reduced that its use in this way had to be discontinued. In the past the hoe, in various forms, was the favourite implement for summer cultivation, but there are now several machines having hooks or tines, lightly constructed, and so easily manipulated that a large area of ground can be worked in a very short time with great benefit to the crops and pleasure to the workman. **James Day.**

Galloway House, Garlieston, N.B.

SWEET PEA AFTERGLOW.

A beautiful mauve-purple variety of fine size and form, raised by Mr. Robert Bolton, Warton, Carnforth.

EARLY CHRYSANTHEMUMS IN THE SOUTH-WEST OF SCOTLAND.

In too many gardens early chrysanthemums have failed to give their usual quota of pleasure to their owners, the long drought having had a great retarding effect upon them, and in quite a number of places they will give few flowers this season unless the frost delays its coming longer than usual. There are, however, a good many exceptions, and the writer himself has no reason to complain, while the garden of a specialist in growing early chrysanthemums which he visited the other day shows that with careful treatment and reasonable care in the way of watering, even 1911 will have proved a satisfactory season, although a fortnight or more late, and a good many of the plants may be overtaken by the frost before they can open.

AN EFFECTIVE DISPLAY OF EARLY-FLOWERING CHRYSANTHEMUMS IN THE QUEEN'S PARK, GLASGOW.

The garden is that of Mr. Joseph Black, Maxwelltown, Dumfries, a small one, yet presenting a collection of varieties such as is seldom seen in the garden of an amateur. There are upwards of 200 varieties this season, and those which were in flower when I visited the place were in magnificent condition, the blooms being very large, of great substance, and of grand colour; while in all the grower's long experience he has never had plants showing so many flowers and buds. A good number were in flower in the last week of September, but many more were to open. Even those which were in bloom would require too much space to detail, but a few notes on some of the varieties may be of service to cultivators. I may add that Mr. Black is a believer in early propagation, and a goodly number of his cuttings were in process of rooting in a frame and under hand lights.

Among the newer varieties to be seen were Belle Mauve, not yet in flower; Fleure de Pecher, just beginning; both being described by their names; Poupre Rose, also late, and of a kind of purple-rose. Rose d'Argent, a lovely white with a blush tinge was very fine, and promises to be a good variety. White Queen is very good, with handsome white flowers, and Thomas Cullen, pink, is capital.

Pluie d'August, white, was truly fine; and Thetis, terra cotta, with a biscuit reverse, was exceptionally good. A magnificent plant of Nat Wheeler was giving no fewer than 220 flowers and buds, and Mrs. W. Sydenham was noted as one of the most floriferous this season, bearing as it did an almost countless number of its flowers and buds of a fine crimson. Mary Sydenham is late, and was not open at the end of September this autumn; while the deep golden-yellow Carmelite, a good flower, though in bloom, was also late. All the Masses are late, but the earliest seem to be White Masse and Improved Masse, with Elstob Yellow. All of these, though late, are very good. White flowers are strongly represented, and have done well, the fine weather having given these flowers greater purity than would have been the case in a wet season, especially as Mr. Black's garden is in a populous part of the town, where there is a good deal of smoke. Cranford White, White Prince, Market White, Parisienne, an old but good flower; Goacher's Pride, very fine; Fred Goacher, really grand; and Emily are all splendid, as are others among the numerous white varieties grown. The weak flower-stalks of Owen's Perpetual lessen the value of an otherwise good variety; but the old pompone, White Pet, is very fine indeed, although its blooms look small beside the magnificent Japanese varieties seen. Ethel Blades, chesnut-scarlet, is grand; Chaldon, reddish-crimson, tipped with gold; Mrs. Howard Jacques, bronze; and the marble-white, lilac-shaded La Tamise are among the best of coloured varieties.

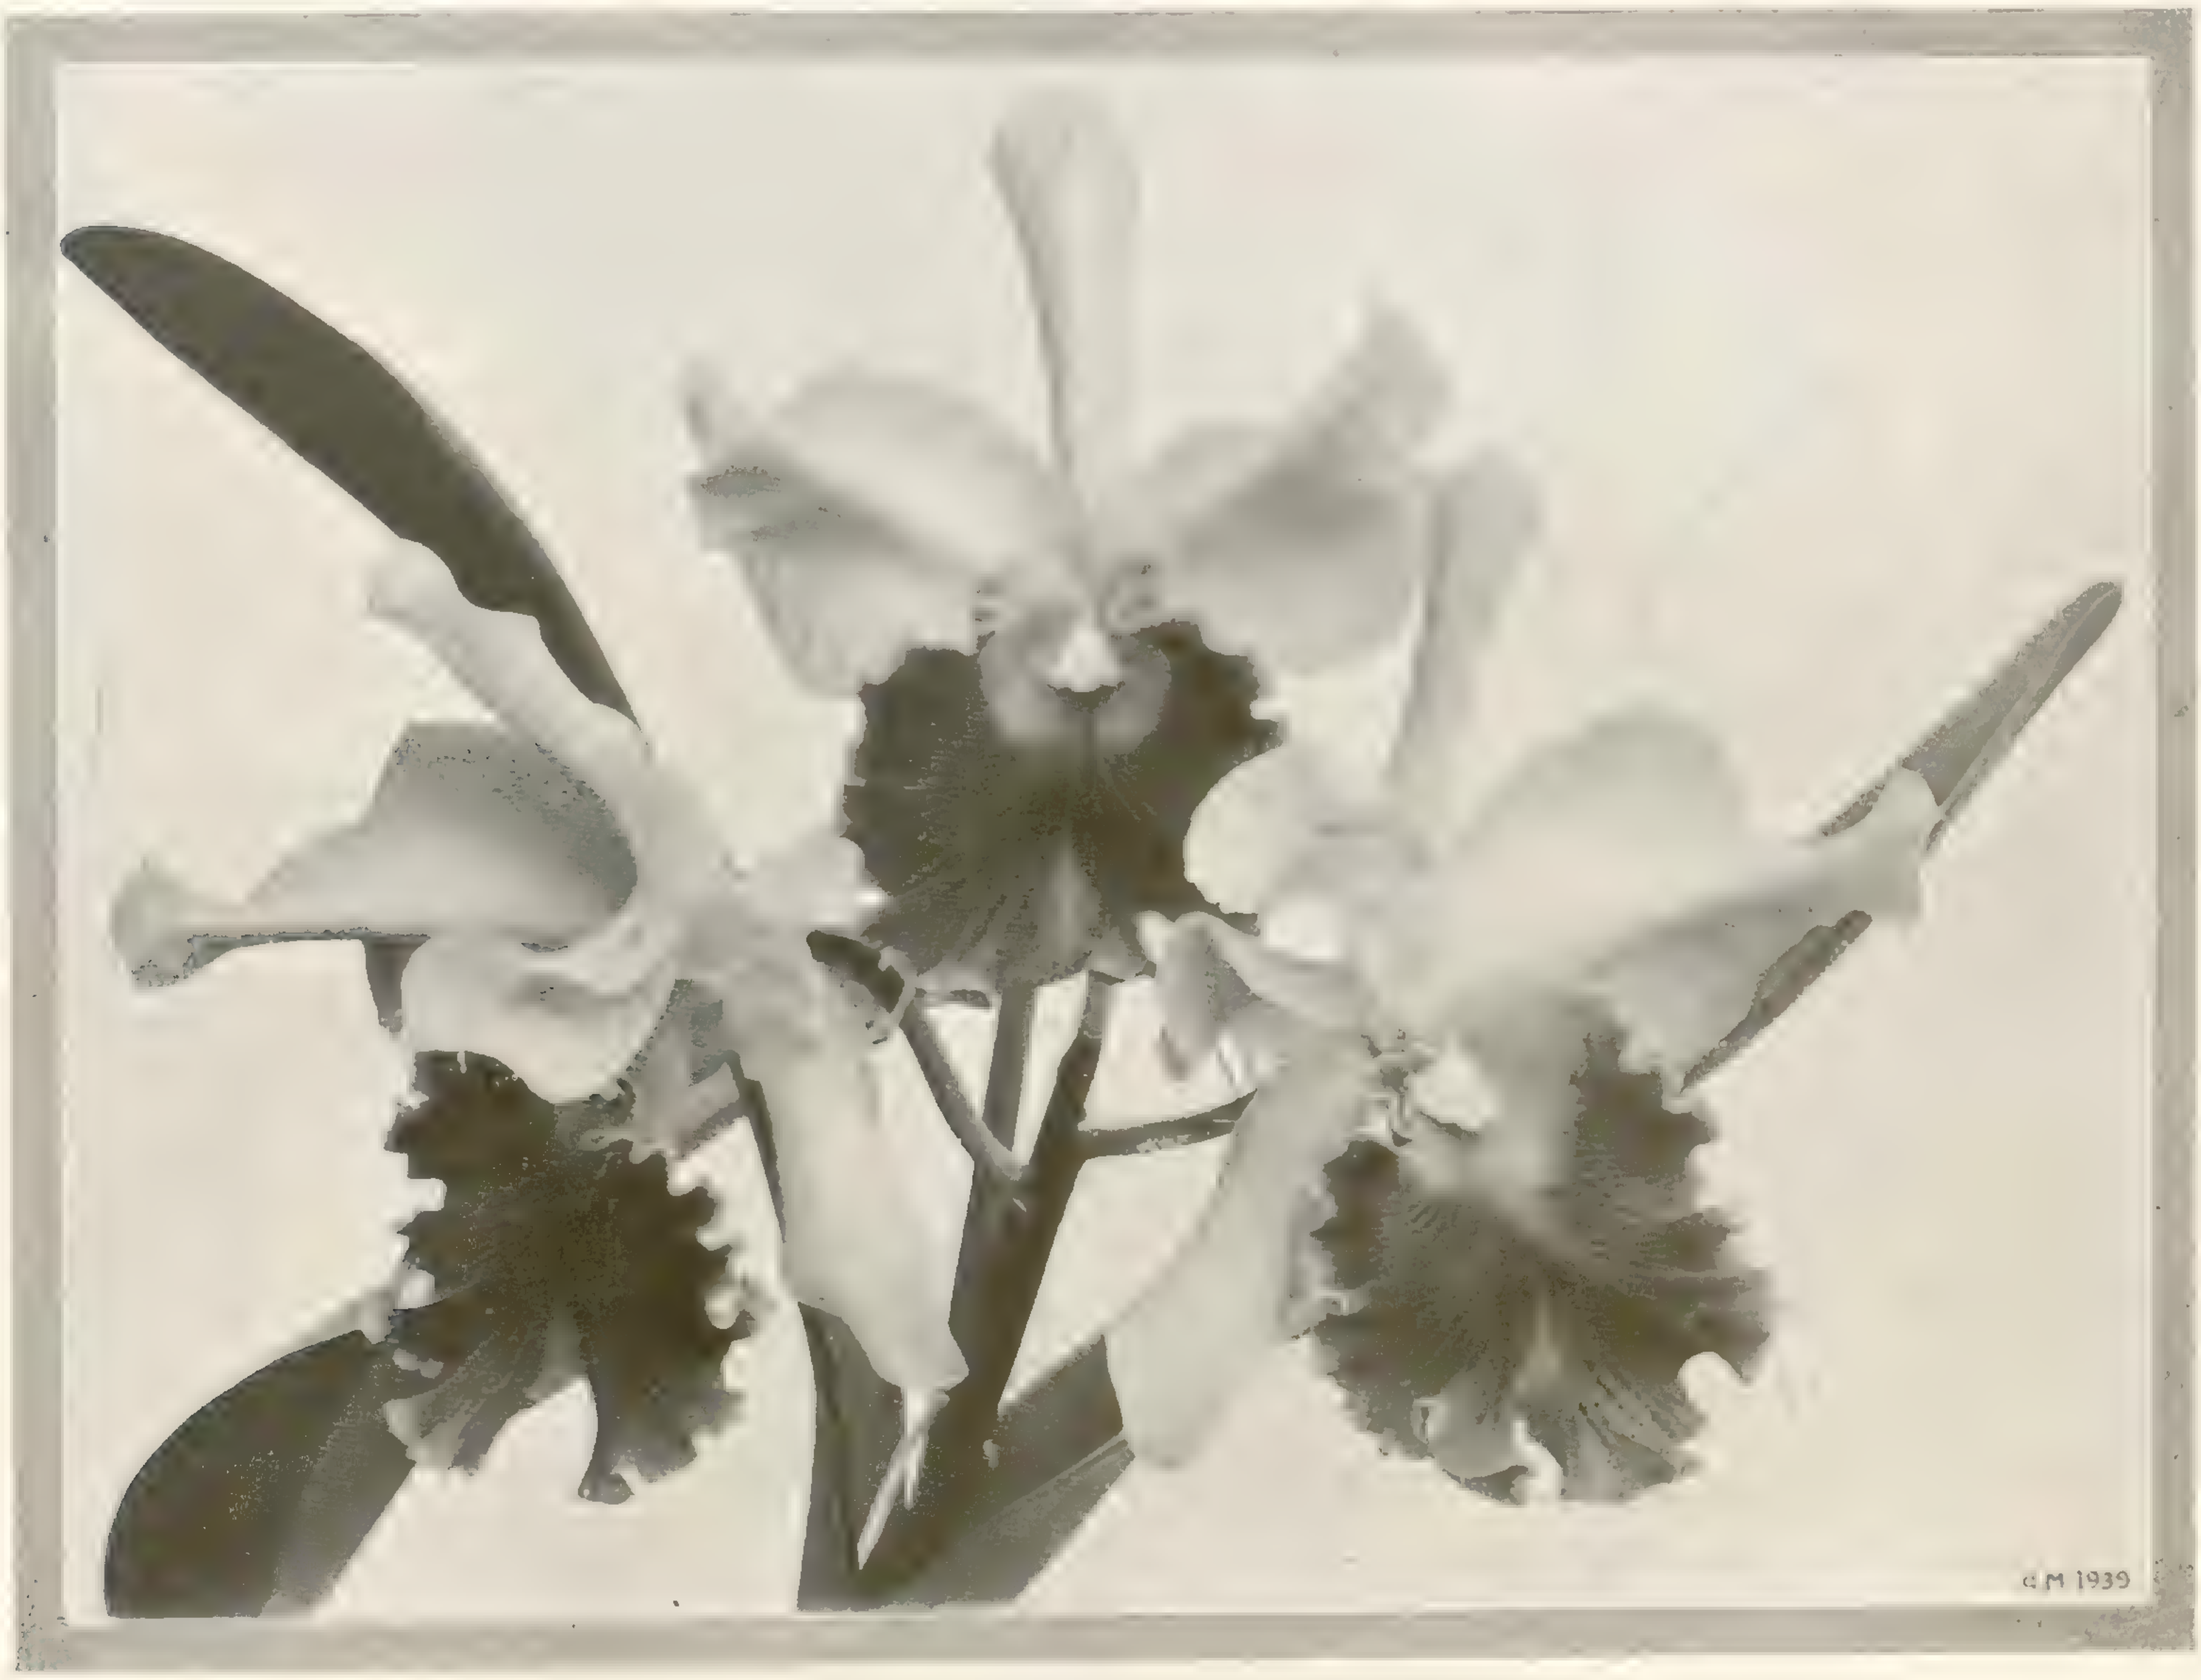
All such good varieties as Polly, Jimmie, Tottie, Maggie, Connie, and several sports from these, are doing in a very satisfactory way, although some of them are later than one would expect. The bronze sport from Polly, called Abercorn Beauty, is excellent. Caledonia, which has promised so well, is late this year, unfortunately, but it is likely to be good should frost delay its more serious approaches.

An exception to the successes is Matthew Pollock, a sport from Lizzie M'Neil, and this will not be tried again, but the lovely Normandie, its second season here, is a valuable acquisition with its fine pink flowers. James Bateman, pink, and Norbet Purvis, golden salmon, are still proving worth their room, with the yellow Leslie and Sybil Quint, which have done splendidly indeed. Mrs. H. Duncan, white, tinted with blush, is excellent, and the lovely porcelain Touraine is one of the best of its colour this year. White Point, although not very large, is pretty and rather better than last season, its pleasing reddish-lilac flowers, with white points, being excellent; while Connie, a good variety for the border, with its nice primrose flowers, was already over, after having flowered very early in summer. Horace Sanders is not quite of the dark rosy-salmon which is said to be its true colour, but since it first flowered in July, shows more sign of realising its proper hue. It is darker than the description would imply. Polly is grand as usual, and is giving magnificent orange-yellow blooms, the yellows, by the way, being truly finely tinted in this dry season. Jenny, orange, is good, as is the old Jimmie, with its crimson-purple reflexing flowers. Horace Martin has been capital, and Rabbie Burns has begun to give a profusion of its fine flowers. Tottie, reddish-orange, is fine, and a sport of Mr. Black's with pure yellow blooms, is an excellent variety of that useful early chrysanthemum.

But time and space would fail one to treat in detail of all the flowers open at the time of my visit; these included such as Carrie, the fine yellow Champ-d'Or; Chatillon, salmon on gold ground; Crimson Diana, and Diana itself, two good flowers (the latter of bronzy orange and the former of the hue the name would suggest), or the bright Dolly Prince, yet holding its own, though late this year. Ethel and Ethel Blades were good; so was Goacher's Crimson and Harrie.

There are many others, while all around the sturdy, healthy plants, the very picture of health, are bristling with buds or laden with bloom. Mr. Black, though an invalid, and often attending to his flowers while racked with pain, is a grower of the first rank, and many professionals might be gratified could they obtain the results he achieves in his small town garden.

S. Arnott.



CATTLEYA MRS. FREDERICK SASSOON.

A beautiful and finely-formed hybrid, with rose-purple flowers, veined in the throat with old gold. A.M., R.H.S., September 26. Francis Wellesley, Esq. (gardener, Mr. W. Hopkins), Westfield, Woking.

[Mr. Arnott's contribution is of special interest to us, for during the past few weeks we have had opportunities for seeing some remarkably fine displays of early-flowering chrysanthemums in the South-west of Scotland, where, generally speaking, the climatic conditions have been more favourable to these flowers than in England. The most effective of the displays that came under our notice was in the old garden that forms so interesting a feature of the Queen's Park, Glasgow, which is one of the most notable of the numerous fine open spaces that are under the skilful management of Mr. J. Whitton. The two borders are wholly planted with forms of Madame Marie Masse, and their high state of development indicates culture of a high order on the part of Mr. McIver, the head gardener at Queen's Park.—Ed. "G.M."]

NEW PLANTS, ETC.

◆

ODONTOGLOSSUM HARWOODI THE SHRUBBERY VAR.

Those who had begun to imagine that hybridisation among odontoglossums could scarcely produce anything finer or more distinct than the beautiful flowers already in cultivation, received a rude shock at the recent R.H.S. meeting, when confronted with the above-named form of the hybrid between O. maculatum auriferum and O. Wiganianum. It is evident that great things may yet be expected from secondary hybrids. O. Harwoodi gained a F.C.C. on January 31, but, fine as it was, this second form is much finer. The flowers are of good size, and the lip is especially broad and attractive; all the segments open out well, so that the blooms are flattish. Bright yellow is the ground colour, and on this there are spottings of dark red-brown (almost black) on the sepals and petals, these markings being mostly on the basal halves. On the lip there are three conspicuous irregular blotches of this dark colour, one on either side of the crest, and one down the centre; the central blotch is sometimes a thick band, but on some of the flowers two shorter bands appear towards the base of the principal one. A few small spots of dark colour are dotted over the rest of the lip. F.C.C., R.H.S., September 26. Messrs. Charlesworth and Co., Haywards Heath.

CATTLEYA MRS. FREDERICK SASSOON.

This handsome cattleya is a particularly fine variety, selected from a batch of seedlings raised at Westfield from a cross between C. Mantini nigricans and C. Dowiana aurea. Three fine flowers were shown, all in the same spike; in form they were up to the highest standard. The sepals and petals are rich rosy-purple, and the broad, open lip is deep rich crimson-purple, with old gold veinings at the base. A.M., R.H.S., September 26. Francis Wellesley, Esq., J.P. (gardener, Mr. W. Hopkins), Westfield, Woking.

EPIDENDRUM LAUCHEANUM.

A very distinct species of exceptional grace. It carried a pair of long, pendulous racemes, crowded for about fifteen inches of their two-feet length with small greenish flowers, each with a yellow-green lip. One spike carried well over a hundred flowers. A.M., R.H.S., September 26. Sir Trevor Lawrence, Bart. (grower, Mr. W. H. White), Burford Lodge, Dorking.

NYMPHÆAS.

N. Earl of Warwick.—A very beautiful new variety of similar character to the foregoing, but with blooms of rosy-mauve colour, with orange centre. A.M., R.H.S., September 20. Earl of Warwick, Dunmow.

N. stellata rosea.—A beautiful and rosy-hued form of the blue N. stellata; the large blooms carried on long, erect stems. A.M., R.H.S., September 26. Leopold de Rothschild, Esq. (gardener, Mr. Jas. Hudson, V.M.H.), Gunnersbury House, Acton.

ROSE RAYON D'OR.

A very pretty new rose, about which a good deal has been said and written of late. It is a member of the new Pernettiana group, and its colour is rich orange-tinted yellow. As shown, the blooms were not very double. A.M., R.H.S., September 26. Messrs. Paul and Son, Cheshunt.

NERINE VEITCHI.

This is regarded as a new species from South Africa, but it has very much the appearance of N. Bowdeni, except that the blooms are of a very soft and delicate blush white colour. The segments are fairly broad, and each bloom has a spread of nearly 2½ inches. A.M., R.H.S., September 26. Messrs. Robert Veitch and Son, Exeter.

DAHLIAS.

Prince de Venosa.—A collarette dahlia of good shape, the inner row of partly-developed white florets showing up strongly against the rich red of the rounded ray florets. A.M., R.H.S., September 26. Messrs. Dobbie and Co., Edinburgh.

Uranus.—See p. 701. A.M., R.H.S., September 26. Messrs. J. Stredwick and Son, St. Leonards.

Golden Wave.—See p. 719. A.M., R.H.S., September 26. Messrs. J. Stredwick and Son, St. Leonards.

Stability.—A stiff-stemmed garden cactus variety, with neat mauve-pink flowers of great beauty. A.M., R.H.S., September 26. Messrs. J. Stredwick and Son, St. Leonards.

Mahdi. — A finely-formed deep maroon single variety. F.C.C., N.D.S., September 20. A.M., R.H.S., September 26. Messrs. J. Cheal and Sons, Crawley.

Queen of the Mauves.—A beautiful single dahlia of bright mauve hue. A.M., R.H.S., September 26. Mr. M. V. Seale, Sevenoaks.

RASPBERRIES.

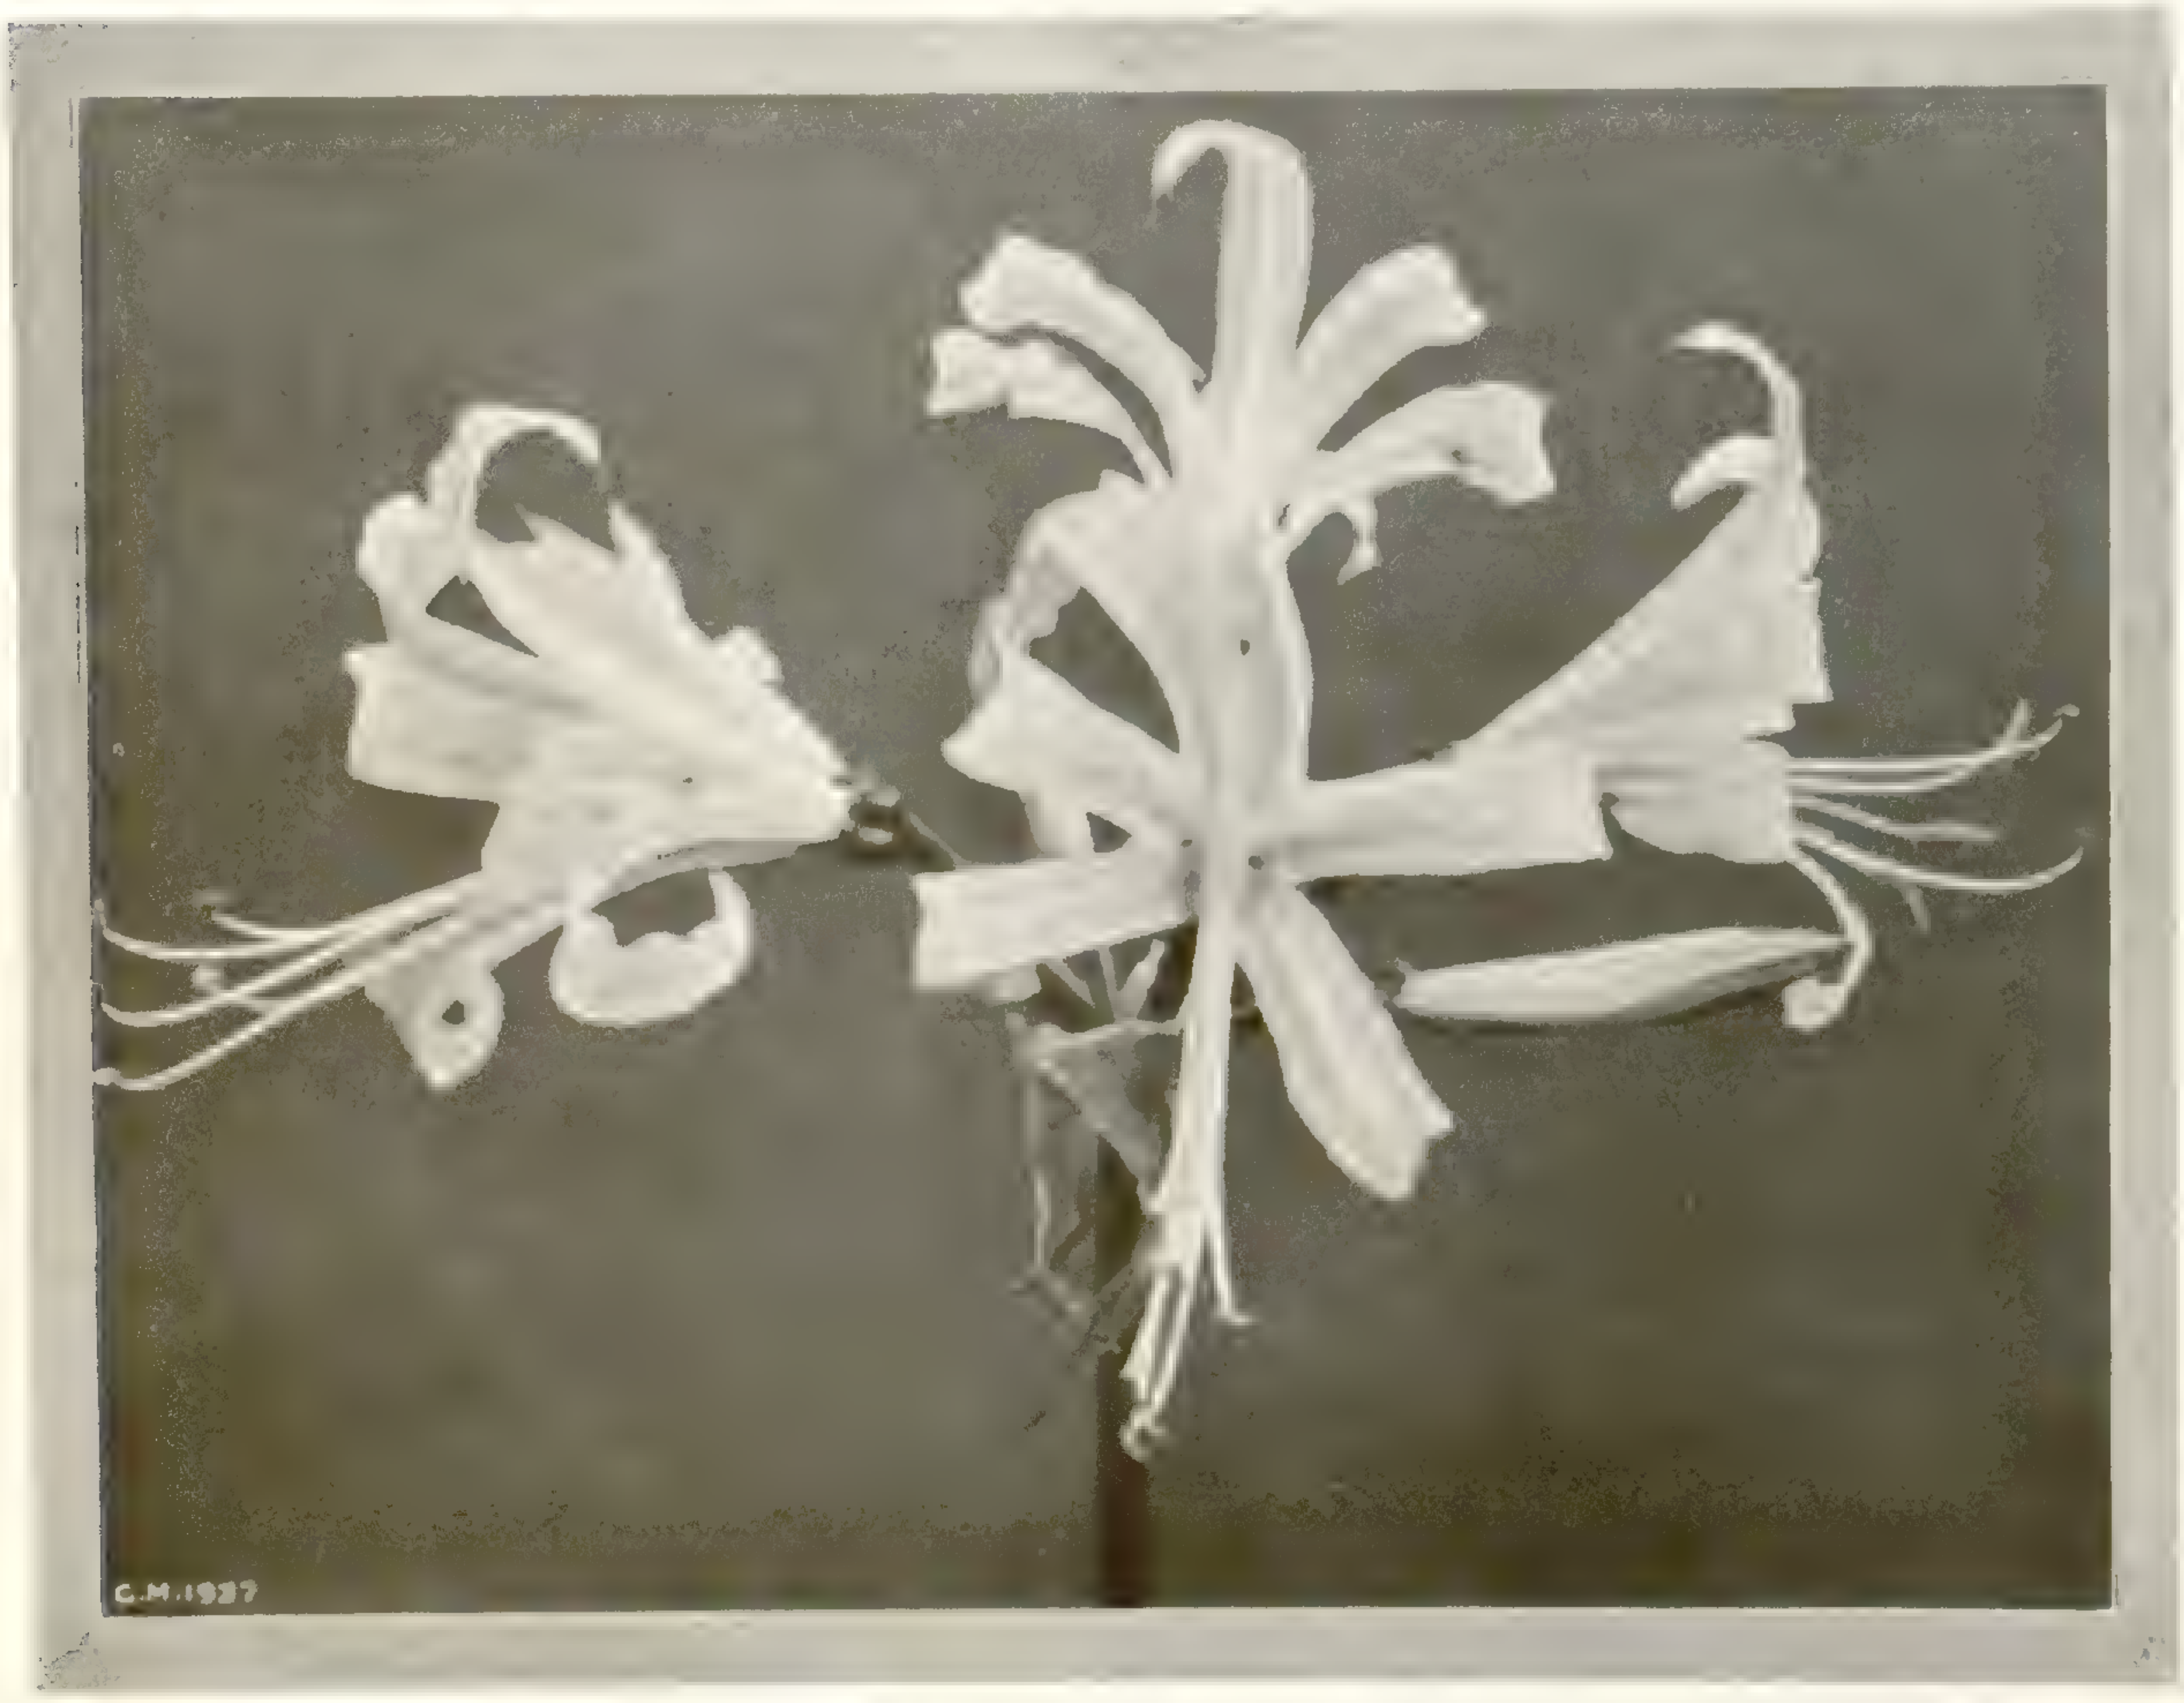
After trial at Wisley, the following varieties of autumn fruiting raspberries were granted an A.M. on September 26; fruiting canes were shown, but scarcely any fruits were left for the general public to see after the committee had risen: Surpasse d'Automne, Surpasse Merveille Rouge, Everlasting Fieldbrummer, and Perpetual de Serriere, from Mr. J. Burn, Cromer; Rouge Merveille from Messrs. G. Bunyard and Co., Maidstone; and Surpasse Fastolf, from Mr. Wilhelm Pfitzer, Stuttgart.

POTATOES.

After cropping tests at Wisley, and cooking tests at Westminster, the following potatoes were each granted an A.M. on September 26: Balgownie Seedling, from Mr. J. Lyule, Aberdeen; Dobbie's Prolific, from Messrs. Dobbie and Co., Edinburgh; Erin's Queen, from Mr. W. E. Sands, Hillsborough, Ireland; Great Scott, from Messrs. R. Veitch and Son, Exeter; and Tremendous, from Messrs. Toogood and Sons, Southampton.

CARROT EARLY GEM

An early and quick-cropping, stump-rooted variety. A.M., R.H.S., September 26. Messrs. Sutton and Sons, Reading.



NERINE VEITCHI.

This new species has blush-white flowers that are as large or larger than those of N. Bowdeni. A.M., R.H.S., September 26. Messrs. Robert Veitch and Sons, Exeter.

MORE BULBS FOR THE ROCKERY.

Many of the smaller bulbous plants are seen to the best advantage when arranged in more or less extensive colonies in the rock garden, and as seen rising above a carpet of greenery, supplied or furnished by suitable alpines, they present a charming picture. In such cases the bulbs should be inserted not less than four inches deep, while regular distribution must be avoided, simply taking advantage of small openings as they occur among the legitimate inmates. A top-dressing of leaf-soil and cocoanut-fibre refuse will act in a dual capacity, namely, protection and the supply of food.

Where space will admit by all means loosen the ground deeply, and add a liberal quantity of screened soil from underneath the potting bench to the staple. It may be explained that the most convenient method of planting small bulbs in colonies on the rockeries is to place four inches of the top soil in a basket or wheelbarrow, when the bulbs may be arranged and the soil returned.

The more refined amongst the narcissi appear quite at home, and are eminently adapted for our purpose. N. triandrus albus (Angel's Tears), N. cyclamineus, N. nanus, N. minor, N. Johnstoni, Queen of Spain, N. gracilis, N. pallidus præcox, and N. juncifolius should be employed with a view to permanent colonies. A nice group of dog's-tooth violets (erythroniums) will arrest attention and excite admiration, and in addition to the ordinary form, E. dens-canis, the following should be planted—E. revolutum, E. giganteum, E. Hartwegi, E. albidum, and E. grandiflorum. From South Africa we get the urepetalums, which are finely represented in U. hyacinthoides and U. viride. They are not perfectly hardy, but are safe enough in a sheltered nook in the rockery.

To ensure success with the watsonias they must be planted in a light sandy soil, and be protected with fibre in winter. Great brilliance is seen in W. humilis, while W. iridiflora O'Brieni is of snowy whiteness. I would strongly advise that Iris reticulata and its varieties be planted, and so arranged that they will be secure from cold winds and heavy rains, preferably under the shelter of boulders. The crocus species afford delightful material both for spring and autumn effects, and they must not be confused with colchicums. By the time these notes appear the autumn bloomers will have done their duty, and they are generally planted early in August, while the spring flowerers receive attention in October and November. C. Balsanæ, C. alatavicus, C. banaticus, C. reticulatus, and C. chrysanthus albidus are first-rate among spring bloomers, the other section being well represented in C. cilicius, C. speciosus, C. longiflorus, C. ochroleucus, C. asturicus, and C. zonatus.

Delicately beautiful are the puschkinias, which contribute their quota of charm to the garden in early spring, and great is the pity that amateurs cannot be induced to take up the culture of not only these, but a host of floral gems that are available for a trifling sum. P. scilloides and P. libanotica are exceedingly pretty. Schizostylis coccinea often presents a stunted and unhappy appearance in the open border, while it luxuriates and yields a wealth of floresence on the rockery, and the same applies to Brodiæa coccinea, which hails from Australia, and calls for a mixture of peat, leaf-soil, and sand.

The delightful little Anomatheca cruenta must not be forgotten, and worthy of mention, too, are the more choice snowdrops. The distinct characteristics of Galanthus Ikari, I. Elwesi, and I. plicatus are seen to advantage in the rock garden. It is true that both the scillas and chionodoxas are happy enough in a well-drained border, but they yield to none for beautiful effect amongst the inmates of the rockery in their season. There are several kinds in each case, and amateurs will find it a good investment to plant a fully representative collection. Walter H. Aggett.

NYSSA AQUATICA.

Though introduced as long ago as 1739 very few really good examples of this tree are to be found in England. This may in part be due to the fact that it is a native of the Southern United States, hence it is hardly likely to thrive in the colder parts of the country. There are, however, many places where it might reasonably be expected to thrive, and, though it may not attain to the size that it grows to in its native habitat, it will form a moderate-sized tree. The flowers are small and inconspicuous, and the ovate or oblong leaves have nothing to redeem them from the ordinary, throughout the summer. On the approach of autumn, however, they assume a vivid shade of red, and it is doubtful whether any other tree is more brilliant during late September and early October.

In America the species is known as the Tupelo Tree, and it assumes its best proportions in swampy ground in Virginia, Carolina, and other southern States. At the present time the wood is being imported into this country as a substitute for the wood of the Tulip Tree (Liriodendron tulipifera), better known amongst timber merchants as yellow poplar. The wood of N. aquatica has several fancy trade names, such as tupelo, bay poplar, etc. It is used for cheap kinds of cabinet work, drawers, house fittings, and various other purposes. In gardens that are of large-size sites on the banks of a lake or stream might with advantage be selected for a few specimens.

W. D.

WALL GARDENING.

Wall gardening has greatly advanced in popular favour during late years, and has proved to be an exceedingly interesting feature. The opportunities offered by a dry wall are many. As the autumn is the most favourable season for planting, it is advisable for those who are contemplating such work to commence at once. The advantages gained by autumn planting over spring planting are not few. In the first place, the autumn atmosphere is humid and more conducive to rooting than the drying winds of spring. When the operation is delayed until the latter season, continual syringings and waterings are necessary to assist the plants, wheras those put out in the autumn will have made sufficient roots to withstand the drying winds. Furthermore, there is not such a press of work in the autumn, and more time can be given to the operation.

When building a dry wall the base should be wider than the top, which means the sides will be slanting. This greatly adds to the stability of the structure, and also offers better facilities for watering as the stones will have a slight downward pitch on the outside. The aspect of the wall must be determined by the space and position at the disposal of the builder. It may be practicable to wall up a shrubbery bank or any steep slope, thus having but one side instead of two. If the wall is built in the open, that is, having two sides, and running east and west, there is abundant material at one's disposal for planting the shady as well as the sunny side.

When one is making a beginning at wall gardening it is best to start with the hardy and easily-grown plants, and add the choicer subjects at a later date. Antirrhinums and wallflowers, of course, are well known and deservedly popular, providing a splendid show when in flower. The rock pinks are extremely useful, adapting themselves well to this method. Aubrietias, helianthemums, alyssums, arabis, and armerias should be largely planted to obtain a quick effect. The edelweiss grows uncommonly well on the top of the wall, fully exposed to the sun, and should have plenty of old mortar rubble mixed with the soil. Antirrhinum glutinosum is an excellent wall plant, delighting in a hot, sunny position. Mesembryanthemums thrive on the sunny parts, but, unfortunately, they are not all quite hardy enough to stand our winters, and should be propagated annually each autumn or late summer. They will winter well in cold frames, provided they are covered during severe weather, and should be planted out the following May. Saponaria ocymoides splendens, Gypsophila repens, Silene Schaftæ, and S. alpestris all adapt themselves to the sunny side of the wall.

There are many choice plants which often succumb to dampness during the winter when grown in the rock garden, yet when established in a wall will give splendid results. These include Edraianthus dalmaticus, E. serpyllifolius, Androsace sarmentosa, A. lanuginosa, A. Chumbyi, Eritrichium nanum, and Æthionema cordifolium.

The campanula family is very accommodating, as it provides material for the shady as well as the sunny side. The beautiful Italian Harebell, C. isophylla makes itself very happy in a sunny position, as also do C. garganica, C. fragilis, C. muralis, and C. Raineri. The encrusted saxifrages, sedums, and sempervivums will be found to thrive wonderfully well in the wall garden.

With regard to planting, undoubtedly the best method is to put the plants in their places as the work of building proceeds. The roots of various subjects can be laid out better, and the plants made tighter, than when the operation is deferred until the wall is completed. What is more, it allows one to provide the soil most suitable for the several kinds. For instance, if ramondias are to be planted in the shady side, peat will be wanted, and if the wall is all filled up with the ordinary soil, that part would have to be removed, consequently the wall must be weakened. This shows the advisability of carrying on the building and planting at the same time. It can be easily accomplished, providing one is careful in handling the stones and soil, so that the plants are not damaged in any way.

ROSE GLOIRE DE CHEDANE GUINOISSEAU.

The splendidly-developed bloom of this fine crimson rose, for which Messrs. J. Cocker and Son were awarded the Gold Medal offered by Messrs. Clay and Son, for the best bloom at the Festival of Empire Rose Show.

Apart from the building of a new wall, there are many old weather-beaten structures existing, which with a little handling offer ample opportunities for planting. In many cases these old walls will be found only partly filled up in the centres, thus providing space for abundance of soil. The rough ridge or top portion should be removed, and the soil well rammed into all the cavities, placing the stones and plants in their positions on the top. For the sides the hammer and chisel will have to be brought into use to provide spaces to accommodate the roots. Additional interest will be afforded by using a few dwarf climbing flowering kinds at intervals, planting them at the base and training the growths over the face of the wall. Plants of coarse or rapid growth should be avoided, or too much space will be required for their development. If desired, a narrow border may be made at the base of the wall, and planted with various dwarf plants and bulbs.

For the shady side of the wall a good selection of hardy ferns should be used, as well as ramondias, corydalis, Arenaria montana, A. grandiflora, and A. balearica. The aubrietias will flower equally as well in the shade as in the sun: in fact, A. Dr. Mules keeps a much better colour in the shade. Primulas viscosa, marginata, involucrata, and nivalis are quite happy in such a position. The mossy saxifrages make a splendid effect in this portion of the wall, and Campanula carpatica, C. pusilla, C. cæspitosa, and C. rhomboidalis are equally at home. An important point to remember when planting is not to place a plant of hanging growth directly above one which has a dwarf spreading habit: thus aubrietia and such kinds should not be arranged so that they cover the mossy saxifrages or ramondias.

Various seeds which may be sown, such as those of erinus, Ionopsidium acaule, Linaria alpina and L. rosea, Dianthus deltoides, Alyssum saxatile, and others. The seeds should be mixed with a little soil, and placed in the crevices or joints of the wall.

E. C. Pooley.

Funkia grandiflora.—Complaints are often made that this funkia does not flower freely, but no exception can be taken this autumn, as probably, owing to the hot season, the long trumpet-shaped silvery-white fragrant blossoms are very numerous. —W. T.

WORK FOR THE WEEK.

CONSERVATORY AND GREENHOUSE.

MALMAISON CARNATIONS.—Some cultivators of Malmaison carnations are forced to defer the potting of this year's layers into larger pots until spring, through lack or space for wintering them, but wherever possible this work should be carried out without delay to enable the plants to root into the new soil before the dull days appear. When potting, especial care must be taken not to bury the collar below the surface, or break the existing ball. Loose potting must be avoided. Providing the potting soil is comfortably moist watering will not be required for a few days. Good plants for next season's flowering will greatly depend on their management during the winter months. They should be given a position as close to the glass as possible. Where shelves are not available they winter very well in frames where a little heat may be afforded in case of frost. Fresh air must be freely admitted on all possible occasions. As the days become shorter and colder the carnations will become less active, therefore the supply of water must be limited, and care exercised in its application. It is preferable to keep the soil rather dry. Excessive damp will produce the much-dreaded disease and rust, and must be avoided; what watering is necessary should be done as early in the morning as possible.

SCHIZANTHUSES. — Plants raised from the early autumn sowing will now be ready for shifting into their flowering pots. The potting material should be fairly rich and porous, and the pots well drained, as schizanthuses resent stagnation. Keep the plants as cool as possible, making no attempt to force them. A position close to the glass where they may receive plenty of light and air is the most suitable. Later-sown batches will be ready for pricking off. A sowing made now will provide stock for flowering next spring.

REHMANNIA ANGULATA.—These will now be ready for a shift into five or six inch pots. As it is a half-hardy subject, no great amount of heat is necessary, although an even temperature must be maintained.

FORCING PLANTS.—As soon as these come to hand they should be potted up. Examine the roots, and if any are found dry they should be soaked before potting. Among the many shrubs which will be found useful for forcing are lilacs, both single and double flowered, laburnums, Deutzia gracilis, Prunus triloba, Pyrus floribunda, Staphylea colchica, Viburnum opulus, Azalea mollis, and A. pontica, and rhododendrons. Among roots we have Dielytra spectabilis, Solomon's seal, spiræas, and lily of the valley.—A. Grubb, Porters Park Gardens.

ORCHIDS.

IMPORTED ORCHIDS.—It is rarely that importations of orchids commence to arrive so early in the autumn as is the case this season, and, judging from the lists that have reached me, it is many years since the importations were so extensive as they appear to be this year. In the case of cattleyas we find such species as C. Trianæ, C. Percivaliana, C. Schroderæ, C. Gaskelliana, C. labiata, C. Warscewiczi (gigas), and C. aurea offered. This will afford opportunities for replenishing the stock, or adding thereto. Few cattleyas retain the robust constitution of their native habitat for many years after importation; there are exceptions in all cases, but I think this will be the general experience. It is not always an easy matter to deal with imported cattleyas at this season of the year, and it is advisable to do no more than encourage a little root action, delaying as far as possible the appearance of new growth until after the turn of the days, when they are less subject to injury from damp, etc.

TREATMENT.—When dealing with imported cattleyas, it is advisable to examine them closely for insect pests, especially the cattleya fly. This is not difficult to detect, as plants that have been attacked have perforations of various sizes in the pseudobulbs; the roots may also be knotted, and if one of these knots is cut asunder the insects may be found in different stages of development. Where these indications are present it is not advisable to introduce the plants to the cattleya house, for if once introduced it is a long time before the pest can be exterminated. It is far better to isolate imported plants than to run any possible risk.

POTTING.—At this season pots just large enough to hold the plants should be used. Plenty of drainage must be introduced, and very little compost should be placed about the roots, the object being to induce root action, and allow a reasonably quick passage of water during the dull winter season. Secure the plants in position by means of sticks sufficiently strong to hold them there being driven among the crocks. Permanent potting may be done after the turn of the year. The plants should not be subjected to over much light when they are first received, as they will have been in the cases for some weeks, and the foliage is liable to become discoloured, and in all probability will die should any sudden or too rapid change be made. It is also better to gradually change from one temperature to another until the desired position is reached. Some of the species will have completed their growth when collected, and some will produce flowers. If rational treatment is afforded to those that have flowers in sheath, quite good blooms are obtainable, which will generally be found sufficient to determine the quality of the variety procured.—H. J. Chapman, Oakwood Gardens.

HARDY FRUITS.

BUSH FRUITS.—New plantations, and the re-arrangement of existing plots of bush fruits may receive attention as soon as the leaves commence to fall freely. The bush form of gooseberries and currants is the most generally adopted, and may be used where sufficient space is available between other fruit trees, such as apples or pears, bush fruit not objecting to a reasonable amount of shade. There is much to be said in favour of the cordon system on wirework for gooseberries, especially where late dessert fruits are required. These through being spurred back, will produce much larger fruits than are obtained from bushes, but naturally the crop will not be so heavy per tree; at the same time every foot of space can be used up and, moreover, by this mode of planting and training, protection by netting against birds can be more easily given.

APPLES.—Only those who have but one or two trees of a variety, especially the later varieties, can know how difficult it is to manage a collection of many sorts; the time wasted at gathering, besides waste that is entailed by having so many little lots is great. It would be much better to give preference at planting time to good, reliable sorts that are known to do well in the district. With cooking varieties this will be a comparatively easy task, as we have at the present time a dozen or two varieties that, with good cultivation and management may be relied upon to give the utmost satisfaction. But a much more difficult problem confronts us in the selection of good reliable dessert varieties. One of the newer ones, James Grieve, promises well, being excellent in every way. Many of the others only justify their existence by being very handsome on the show table, but varieties of apples seen frequently at the fruit shows must not be taken as a reliable guide to their value for home use. Beauty of Bath, American Mother, Allington Pippin and Brownlees Russet, have something to recommend them, and, as this is Cox's Orange Pippin year, many will still have hope, and plant a few more trees of this variety, only to meet with disappointment later, in all probability.

PEARS.—The above remarks on apples do not apply in the same sense to pears. To keep up a succession of dessert pears many varieties will be required, their season in most instances being of short duration. Walls with an east or west aspect are usually given up to pear trees, and if cordons are adopted many varieties can be grown in a given space. The smaller fruiting varieties are usually the most reliable croppers, and, after all, pears a pound weight and upwards can scarcely be considered good for dessert; I have in my mind such varieties as Pitmaston Duchess, Beurre Mortilet, Beurre Baltet Père, and a dozen others, all very gratifying to the eye; but when planting the chief consideration should be flavour, hardiness, and cropping capabilities. Marie Louise, Beurre Superfin, Beurre Hardy, Conference, Doyenne du Comice, and Glou Morceau are all first-class, and with, perhaps, the exception of Marie Louise, all may be grown in the open as bush, pyramid, or cordons with success. There are very many other excellent dessert pears, both early and late, which, if wall space can be devoted to them, will prove of the greatest service in keeping up a regular supply.—J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

CAULIFLOWERS.—Seeds sown last month will have produced plants sufficiently large to prick out into cold frames for protection. Select an open, porous, and sweet soil, and add to it soot or wood ashes. Allow a space of about six inches between the plants, and grow them along as hardy as possible by exposure until frost arrives; then the lights may be placed on the frames, and protection given according to the severity of the weather, but always during fine days give the plants plenty of air. The Autumn Giant cauliflowers have, owing to the long drought, been almost a failure in many places. Where the heads are turning in break some foliage down over them to protect from frost. Should sharp weather set in it will be better to lift them and plant thickly in sand or ashes in an open shed.

GLOBE ARTICHOKES.—Where the stock requires replenishing now is a good time to secure good strong off-sets. They can be potted up and placed in a cold frame for protection during the winter months. If everything has gone well, they will be satisfactory plants for planting out in April or May, and will fruit the first year. The old plants, too, will need protection; dry leaves packed round the crowns, with a covering of straw to keep them in position, will be sufficient in most parts of the country.

CHICORY.—From now onward lettuces will be scarce, and chicory will be required, to some extent, as a substitute for them in the salad bowl. Have a portion of the roots lifted and planted in the mushroom house. In about three weeks they will give useful blanched leaves. The main batch of plants will yet grow and improve if left in their present position.

CELERY.—The late celery will be growing freely now, and a beginning will be necessary with the blanching process. It is much the best plan to add small quantities of soil at short intervals.

TRENCHING.—Many crops will be cleared from the ground after this date, and the work of manuring and trenching can be commenced. I am aware that it cannot always be carried out, but so far as possible a definite plan should be made for next year's cropping. Then the manuring, trenching, or digging can be arranged accordingly. The deep-rooting plants should occupy the rich trenched land, and the less particular ones the ordinary dug positions. Where possible, too, it is better to take in hand the heavier ground first, and allow it to have the longer season for exposure.

GENERAL REMARKS.—As the staff can be spared from the urgent work in the garden, and during bad weather, there will most probably be old hotbeds that are most valuable, and will require turning over to encourage further decomposition, or can be mixed with other manure. The rubbish heap, too, is of great value to the kitchen garden, and will require attention in turning and picking over. Protecting material will need to be in stock. Bracken, if cut before frost, is valuable for the rougher positions in the frame ground.—Charles Flack, Cholmondely Castle Gardens.

CROYDON CHRYSANTHEMUM SOCIETY.
24th AUTUMN SHOW, ADULT SCHOOL. PARK LANE. WEDNESDAY and THURSDAY,
OCT. 25th and 26th.
Challenge Cups, £35, with £20 money. Total Prizes over £100.
Entries close Oct. 19th.
W. B. BECKETT, "Woodcote," Purley.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Festival of Empire Rose Show.

The autumn exhibition held at the Crystal Palace on September 28 and 29, was arranged in the centre of the great building, and proved an attractive function.

The schedule consisted of fifty-three classes, and not a single cash prize was offered, all the awards being cups, plate, or medals, and these were in nearly every case presented by amateur or trade rosarians, Festival officials, and friends. In the matter of quality the roses were something of a surprise, not a few being really good, and exceptionally so if the season is duly considered. In the matter of arrangement, the show left something to be desired, as many of the "display" classes were set upon the central tables against a high background of green material and woodwork, the scaffolding of which was patent to everyone on the hither side, rising above smaller exhibits behind. Such classes should have had a place along the sides, or at the end in front of the Royal Box, where they would have been very effective.

In the following notes we refer to the chief classes and exhibits, as it is not possible for us to deal with every class.

NURSERYMEN.

Premier award for the best thirty-six blooms, distinct, fell to Messrs. J. Cocker and Sons, Aberdeen, for some beautiful flowers, notably of Lyon, Gloire de C. Guinoisseau, Captain Hayward, Yvonne Vacherot, Frau Karl Druschki, and Mrs. T. Roosevelt; Messrs. Adam and Craigmile, Rubislaw, Aberdeen, came second; and Mr. Hugh Dickson, Belfast, third. We venture once more to raise a protest against the excessive dressing of the blooms in this class.

For twenty-four blooms, distinct, Messrs. D. Prior and Sons, Colchester, led from eight other competitors, and their best blooms were of Maman Cochet, W. R. Smith, White Maman Cochet, Mdme. C. Guinoisseau, and Oberhofgartner Terks; Mr. George Prince came second; and Mr. Frank Woolard, Lewes Road, Brighton, was third.

Mr. Hugh Dickson contributed a grand set of eighteen blooms, and was easily first in this class, with rare flowers of Konigin Carola, Gladys Harkness, Caroline Testout, Lieut. Chaure, Lohengrin, W. E. Lippiatt, Frau Karl Druschki, Lyon, Mrs. D. McKee, Leslie Holland, Earl of Warwick, Cardinal, Marquis de Ganz, J. B. Clark, Mdme. J. Combet, Hugh Dickson, Mdme. Wagram, and Lady Alice Stanley; Messrs. J. Cocker and Sons, Aberdeen, second, and in their set they had a magnificent flower of the crimson Gloire de Chedane Guinoisseau, which gained Messrs. Clay and Son's Gold Medal as the best flower in the show; Messrs. Adam and Craigmile third.

In the dozen bloom class, Mr. Henry Drew, Longworth, Berks, annexed the chief award with good clean blooms, and was followed by Mr. J. Mattock and Mr. W. Tayler, Hampton. There were eleven entries in the class for twelve blooms of one variety, and here Messrs. Alexander Dickson and Sons, Newtownards, scored with very clean examples of Frau Karl Druschki; Messrs. D. Prior and Son second, and Mr. F. Wooland third, each with the same variety. Messrs. Prior and Sons had the finest set of twelve blooms of a tea rose, and they showed Maman Cochet well; Mr. Prince second, and Mr. H. Drew third, each with White Maman Cochet.

Messrs. J. Cocker and Sons scored for eight trebles, and were followed in order by Mr. Hugh Dickson and Messrs. A. Dickson and Sons. In the class for a dozen trebles there were four competitors, and Messrs. Jas. Cocker and Sons again led, their set including Lyon, Mdme. Wagram, Mdme. J. Combet, and Frau Karl Druschki in fine form; Mr. Hugh Dickson second, and Messrs. Adam and Craigmile third. Six competitors entered for six varieties, three blooms of each, and Messrs. S. Treseder and Son, Cardiff, led with Marie Van Houtte, Florence Pemberton, Medea, Maman Cochet, Earl of Warwick, and White Maman Cochet; Messrs. D. Prior and Sons, Colchester, second; and Mr. G. Prince, Longworth, third.

In the leading tea rose class, for eighteen blooms, distinct, Mr. G. Prince was the best of three entrants, and he presented charming flowers of W. R. Smith, Mrs. E. Mawley, Souv. de Pierre Notting, Maman Cochet, and White Maman Cochet; Messrs. J. Jefferies and Son, Cirencester, second; and Messrs. W. Crisp and Sons, Colchester, third. For a dozen teas Messrs. Adam and Craigmile scored with a very clean set of W. R. Smith, Mdme. Louise Leroy, Nita Weldon, Mdme. Constant Soupert, etc.; Messrs. Frank Cant and Co., Colchester, second; and Messrs. Stephen Treseder and Son, third.

Mr. Hugh Dickson was a capital first for a dozen vases of exhibition roses, seven blooms in each; Lyon, Frank Thorpe, Miss Cynthia Forbes, and Mrs. D. McKee were very well shown; Messrs. G. Prince second. Messrs. J. Cocker and Sons scored for a vase of any rose with big flowers of Frau Karl Druschki. Mr. J. Mattock, Headington, Oxford, who has not been beaten this year for decorative roses, led on this occasion with a display of twenty-four bunches with charming flowers of Betty Berkeley, Mrs. A. Tate, Mdme. Ravary, Mdme. Jules Grolez, Betty, Lady Battersea, Gustave Regis, etc.; Mr. George Prince, and Messrs. Frank Cant were placed second and third respectively. Messrs. B. Cant and Sons, Colchester; Messrs. W. Spooner and Sons, Woking; and Mr. George Prince, Oxford, were placed as mentioned, for a dozen bunches of polyantha roses, while for a similar number of bunches of decorative roses, Messrs. W. Spooner and Sons, Mr. F. M. Bradley, and Messrs. S. Bide and Sons, Farnham, scored as placed.

Messrs. W. Spooner and Sons were easily first for a dozen bunches of decorative roses, their General McArthur, Mdme. Abel Chatenay, and Ecarlate being especially good; Mr. F. M. Bradley, Church Street, Peterborough, second; and Messrs. S. Bide and Sons, Farnham, third.

Mr. Hugh Dickson scored for a dozen blooms of new roses, and his best were Miss Cynthia Forbes, Marchioness of Waterford, Duchess of Wellington, Mrs. H. Stephens, and Colonel Leclerc; Messrs. Alex. Dickson and Sons, second; and Messrs. S. Bide and Sons, third. First prize for a new rose fell to Messrs. Alex. Dickson and Sons, Newtownards, for the yellow A. Hill Gray; Mr. Hugh Dickson coming second with Souv. de Portland, Oregon; and third with Mrs. J. W. Parker.

Messrs. W. and J. Brown, Peterborough, won the trophy offered for the best representative collection of roses arranged on a space 18ft. by 6ft.; at the back they had sprays of rose hips carried up 8ft. or 10ft. high, and in front they put up big stands of Lyon, White Maman Cochet, Pharisaer, J. Hill, Maman Cochet, and La Tosca, with small vases making up the groundwork; Messrs. B. Cant and Sons came second with a lower group.

A group of roses to fill a space of 60 square feet, is a fairly big order at this time of the year, but two competitors came forward in such a class, and Messrs. J. Jefferies and Son, Cirencester, won first place with a capital exhibit of popular roses, arranged in stands and vases of varying height, but one that was somewhat marred by the tall stand of Perle des Jardins, wherein the flowers were disposed in three rigid vertical lines; Messrs. Jackman and Son, Woking, second.

AMATEURS.

Mr. Conway Jones, Gloucester, was to the front for twenty-four blooms, distinct, and he set up good flowers of Maman Cochet, White Maman Cochet, and Madame Jules Gravereaux, but he, like his competitors, had a number of poor flowers; the Rev. J. H. Pemberton, Havering, second, and Mr. W. Boyes, Middleton, Yorks, third. Mr. G. A. Hammond, Burgess Hill, was the only exhibitor of a dozen flowers. The Rev. J. H. Pemberton and Mr. Conway Jones took first and second places for a dozen trebles. Frau Karl Druschki won first place for the Rev. J. H. Pemberton in the class for a dozen flowers of one variety; Mr. Boyes was second here with the same variety, and Mr. Conway Jones third with Souv. de Pierre Notting.

Mr. F. Slaughter, Steyning, won the cup for eighteen blooms, while Mr. Raman de Escott, Kingsley Dene, Dulwich, and Mr. H. R. Darlington were first and second respectively for twelve blooms. In the smaller growers' sections we noticed that Mr. E. B. Lehman, Hield Lodge, Crawley; Mr. J. N. Stuart, Mount Park, Harrow; Mr. F. Thorpe, Victoria Terrace, Enniskillen; Mr. P. S. Davis, Burgess Hill, Sussex; Mr. W. Fowler, Mill Hill; M. Panckridge, Petersfield, won leading prizes.

Mr. Conway Jones and Mr. Slaughter had no competitors in classes for eighteen and twelve tea roses respectively, while in the tea rose classes, the Rev. F. P. Burnside, Great Stambridge Rectory, Essex, led.

Mr. S. W. Burgess, Old Bank House, Tonbridge, beat Mr. Conway Jones for seven vases of roses, and each put up a good set. Mr. Hammond beat Mr. Conway Jones for three vases of tea roses, and he had lovely flowers of Maman Cochet, White Maman Cochet, and Madame Jules Gravereaux. For one vase of a tea rose, Mr. P. S. Davis, Burgess Hill, scored with White Maman Cochet.

Mr. Conway Jones's first-prize exhibit of a dozen bunches of garden roses was a capital one, and his vases of Anna Olivier and Madame Antoine Marie were very fine; Mr. H. R. Darlington came second, and the Rev. J. H. Pemberton third. For six bunches Mrs. J. Walter Smith, Sparrows Herne Hall, Bushey, won first prize.

DECORATIVE CLASSES.

In the decorative classes Mrs. J. Bride, Cathcart, Uxbridge, had the best vase of roses, one variety, showing Lady Hillingdon; Mrs. Tisdale, Woodford Green, came second with Maman Cochet, Mrs. G. W. Cook, Radstock, Whetstone, obtained the chief award for a basket of roses, and scored with Lady Hillingdon; Mrs. A. R. Bide, Farnham, second. Mrs. J. Bide had the best bowl of roses, winning with a pleasing arrangement of Mrs. George Shawyer; Mrs. A. R. Bide second. Mrs. G. W. Cook was first for buttonhole sprays.

Mrs. J. Bide's table decoration of yellow Lady Hillingdon was a very pretty one, and Mrs. Bide wins a handsome green bowl in a silver stand; Mrs. A. R. Bide won second prize, and Mrs. G. W. Cook third.

NON-COMPETITIVE.

Hardy fruits were finely displayed by Messrs. W. Seabrook and Sons, Chelmsford, who set up very bright and large samples of Blenheim Pippin, Lord Suffield, The Queen, Peasgood's Nonsuch, Ribston Pippin, Newton Wonder, and other popular apples in heaped-up baskets of a variety.

An especially large and interesting contribution of fruit came from the Herefordshire Fruit Growers' Association, Hereford; this consisted of well over a hundred 28lb. boxes of finely-graded apples, as well as numerous dishes of extra fine samples. Altogether, there was about two and a-half tons of first-class fruit for the best-class markets. The exhibit was a grand advertisement for Herefordshire-grown and packed fruits. The varieties shown were almost all well-known sorts, but we may make special mention of the splendid specimens of Peasgood's Nonsuch, Stirling Castle, Blenheim Pippin, Broad Oaks, Allington Pippin, Cox's Orange Pippin, Tom Putt (very brilliant), Warner's King, Tyler's Kernel, Loddington, Bramley's Seedling, Mère de Ménage, James Grieve, Bismarck, Devon Red, Annie Elizabeth, and Gascoigne's Scarlet. About fifty varieties were exhibited and sent by a total of twenty-two growers, chiefly from the Ross and Hereford districts.

Mr. Neal, gardener to J. A. Nix, Esq., Tilgate, Crawley, brought up a fine collection of fruit, showing as large a display as at the R.H.S. meeting of the previous Tuesday; there were apples, pears, peaches, nectarines, melons, and grapes, in choice selection.

Mr. J. Box, Lindfield, had a quite large and very graceful group of Michaelmas daisies, phloxes, solidagos, delphiniums, and early chrysanthemums, the whole forming a display of great beauty and interest at this season of the year. Mr. A. Edwards, Arnold, Notts; Mr. J. Pinches, Camberwell; and Messrs. White and Son, Paddock Wood, were also exhibitors on this occasion.

Messrs. J. Jefferies and Son, Cirencester, were exhibitors of well-grown hardy fruits, their contribution consisting of about a hundred dishes of apples and pears. A circular central exhibit, temple fashion, from Messrs. James Carter and Co., Raynes Park, was composed of dahlias in great variety, with a central mass of Solidago Golden Wings, and the arches well furnished with bowls and baskets of Comet, quilled, plumed, and single asters in a great range of colouring. Mr. H. Morse, Eaton, Norwich, staged a few dozen low bowl-like arrangements of roses that formed a pleasing exhibit.

Manchester and North of England Orchid Society.

At the meeting held on Thursday, September 28, the members of committee present were Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, W. R. Lee, C. Parker, H. Thorp, Z. A. Ward, J. Cypher, J. Evans, W. Holmes, A. J. Keeling, D. McLeod, W. Stevens, and H. Arthur (secretary).

W. R. Lee, Esq., Heywood (gardener, Mr. Woodhouse), was awarded a silver medal for a group of plants, consisting of cattleyas and cypripediums, the most noticeable cattleyas being C. St. Gothard, F.C.C., C. Iris var. Cæsar, F.C.C., C. Iris var. Ixion, A.M., C. Priam, and C. Venus, Plumpton Hall var. Of the cypripediums, C. Boltoni and C. gigas Corndean Hall var. were well shown.

Z. A. Ward, Esq., Northenden (gardener, Mr. Weatherby), was awarded a silver medal for a group—quite a collection—of Odontoglossum grande, with cattleyas and cypripediums, making a fine display; Cattleyas Ashtonæ, C. Germania, A.M., and C. Iris, var. G. Weatherby, A.M., were the most noteworthy; several hybrid cypripediums were of high quality.

J. McCartney, Esq., Bolton (gardener, Mr. Holmes), staged a good group, to which a silver medal was awarded consisting principally of cattleyas and hybrids of the section, John Baguley, Mrs. Pitt, Princess Patricia, and Minuca were amongst the best; several cypripediums, including C. callosum Sanderæ, were also exhibited in capital style.

Colonel J. Rutherford, M.P., Blackurn (gardener, Mr. Lupton), was awarded a bronze medal for a small mixed group, including a fine form of Cattleya Maroni, Odontoglossum ardentissimum, a good O. crispum, Lycaste Skinneri alba, and several excellent cypripediums.

J. J. Holden, Esq., Southport (gardener, Mr. Johnson), staged splendid forms of Cattleya Iris, var. Golden Queen A.M., C. Adula Auburn House var. A.M., and a good example of Cypripedium Juliet.

William Thompson, Esq., Walton Grange (gardener, Mr. Stevens), contributed Cypripediums Germain Opoix and Gaston Bulteel—very fine forms. H. J. Bromielow, Esq., Rann Lee (gardener, Mr. Morgan), also staged a good plant of C. Germain Opoix.

Messrs. Stuart Low and Co., Bush Hill Park, submitted a fine form of Cattleya Hardyana, var. Enfieldensis, F.C.C., and C. Gaskelliana var. Delight A.M. Messrs. A. J. Keeling and Sons, Bradford, had Cypripedium Actæus, Westgate var. A.M., and Curtisi x vexillarium, A.M.

AWARDS.

First-class Certificates.—Cattleya St. Gothard, from W. R. Lee, Esq., Heywood (gardener, Mr. Woodhouse), a noble flower, very even colour, with intense lip. Cattleya Iris, var. Cæsar, from the same exhibitor—a well-formed flower, almost round, sepals and petals plum colour, with deep lip. Cattleya Hardyana, var. Enfieldensis, from Messrs. Stuart Low and Co., Bush Hill Park—a very fine type, large flower, good colour, and well lined in the lip.

Award of Merit.—Cattleya Iris, var. Ixion, from W. R. Lee, Esq., Heywood (gardener, Mr. Woodhouse)—a flower of good shape and rich in colour. Cattleya Germania, a good specimen, well flowered, very bright. Cattleya Iris var. G. Weatherby, one of the largest forms of the type yet seen; and Cypripedium Euryades x Parkerianum—a massive bloom, following almost entirely the Parkerianum parent, from Z. A. Ward, Esq., Northenden (gardener, Mr. Weatherby). Cattleya Iris, var. Golden Queen—a most delightful variety, of a bright golden colour; and Cattleya Adula, Auburn House var., a well-set flower, very distinct in colour, from J. J. Holden, Esq., Southport (gardener, Mr. Johnson). Cattleya Gaskelliana, var. Delight, from Messrs. Stuart Low and Co., a pleasing flower with white sepals and petals and lip faintly lined. Cypripedium Acteus, Westgate var.—a fine, well-balanced flower, good colour; and Cypripedium Curtisi x vexillarium—a good form, and finely-coloured, from Messrs. A. J. Keeling and Sons, Bradford.

National Chrysanthemum Society.

The early exhibition of this society, held at the Crystal Palace on Wednesday and Thursday, October 4 and 5, was not such a good one as many of its predecessors, owing to the effects of the hot and dry summer upon plants in southern gardens. Competition was very poor, but the trade exhibits lent importance to the exhibition, and Mr. Smellie's Scottish-grown flowers were a fine feature.

There was only one entry in the class for a dozen Japanese blooms, distinct, and this, from Mr. W. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, was awarded first prize; his best flowers were of White Queen, Miss A. Finch, Mary Poulter, Mrs. H. Thornton, and Mrs. L. Thorn. For six blooms, Mr. F. Cordell, gardener to A. F. Blades, Esq., Rookfield, Reigate, was a very capital first with fine flowers of Mrs. L. Thorn, J. H. Molyneux, Hon. Mrs. Lopes, Mrs. A. T. Miller, Rose Pockett, and Mrs. F. C. Stoop; Mr. A. Dyer, gardener to E. Wood, Esq., The Tyrol, Upper Norwood, came second; and Mr. W. A. Ballard, Abbey Lane, Leicester, was a long way behind for third place.

The Scottish flowers saved the situation on this occasion. Mr. J. Smellie, Busby, near Glasgow, was the only exhibitor of a dozen bunches of early-flowering pompon chrysanthemums, not fewer than eight varieties, and gained the first prize with beautiful bunches of Fred Pelé, Mignon, St. Crouts, Scarlet Gem, Bronze Blushing Bride, W. Piercy, and the old Piercy's Seedling.

Mr. J. Smellie had matters in his own hands in the class for a dozen bunches, distinct, of early-flowering chrysanthemums grown in the open. Probably no finer set than that with which he won first prize has ever been seen at a Southern show; he put up large and very beautiful bunches of White Masse, Dolly Reeves, Estob Yellow, Crimson Diana, Caledonia, Nina Blick, Hector, Leslie, Roi des Blancs, Lillie, Diana, and Hecuba; Mr. W. A. Ballard, Leicester, came second, but he was awarded first prize for a dozen bunches undisbudded, and was the only exhibitor in the class.

Mr. J. Smellie scored for six bunches of early-flowering pompons, and his set consisted of Bronze Blushing Bride, Scarlet Gem, Blushing Bride, Mignon, St. Crouts, and La Luxembourg. For a similar number of bunches of disbudded early chrysanthemums, Mr. Smellie won with graceful flowers of Jas. Bateman, Caledonia, Hector, Dolly Reeves, Hecuba, and Lillie; Mr. W. A. Ballard, second.

The best bunch of one Japanese variety, three blooms, came from Mr. W. Mease, who scored with the popular White Queen; Mr. C. Fox, second; and Mr. A. Smith, gardener to Mdme. Stuart, The Convent, Roehampton, third; there were five entries. Mr. W. H. Newton, Potter's Bar, had the best vase of single early blooms, yellow or bronze, with Mr. Smellie second.

Mr. Smellie led for white single varieties, one bunch, with Mr. F. Brazier second. Mr. Smellie and Mr. Brazier were first and second respectively for one bunch of mixed early single varieties, and Mr. Smellie's was a very handsome bunch.

Mr. Brazier was the only exhibitor of a group of flowers and foliage, and he was awarded first prize.

In the amateur division, Mr. C. Fox, Linden Gardens, Tunbridge Wells, led for six bunches of early chrysanthemums with good blooms, rather too closely packed into the vases; Mr. F. Cordell second. One vase of single chrysanthemums was staged, and this from Mr. W. H. Newton, gardener to Mrs. McDowell Nachan, Potter's Bar, was granted a first prize. Mr. Fox and Mr. Cordell were first and second respectively for three bunches of early varieties.

FLORAL DECORATIONS.

Mr. F. Brazier, Caterham, secured first prize for a table of floral designs, with harps, bouquets, and vases of chrysanthemums neatly arranged. Mr. A. W. Trossall, The Parade, Beckenham, was placed first for three epergnes with arrangements of yellow and red-bronze flowers lightly disposed; Mrs. A. Robinson, Norhyrst, Carshalton, was second with a very pleasing set, and Mr. T. W. Stevens, gardener to W. H. Stone, Esq., Donnington, Laurie Park, Sydenham, third.

Mrs. Maslin, Addlestone, was placed first for a basket of autumn foliage and berries, and she used pernettya sprays largely; Mr. F. Brazier second, with a rather stiff design. Mrs. Martin led for a vase of chrysanthemums suitable for table decoration, with a handsome set of rich bronze and yellow blooms; Mr. C. Fox second, and Mr. T. W. Stevens third.

For an epergne of blooms Mr. C. Fox, Mr. A. W. Trossall, Beckenham, and Mr. T. W. Stevens were placed in the order given. Mr. F. Brazier was first for abasket of chrysanthemums, and he used red-bronze and white flowers with sprays of oak leaves and kochia.

NEW VARIETIES.

First Class Certificate.—To Bronze Goacher's Crimson, from Messrs. W. Wells and Co.; to Miss E. Finch, a terra-cotta single, from Mr. Brazier, Caterham; to Emperor, crimson and gold, and to an unnamed white, from Messrs. Lowe and Shawyer, Uxbridge.

Commendation.—To Phœbe, pink Japanese, from Mr. H. W. Thorpe, Durrington, Worthing; to Roundabout, a golden-bronze border variety, from Mr. H. W. Thorpe; and to Eskimo, large cream-white, from Messrs. Lowe and Shawyer, Uxbridge.

NON-COMPETITIVE.

Mr. Norman Davis, Framfield, Sussex, had a large and very bright display, wherein, backed by tall palms and associated with suitable greenery, there were numerous tall, well-filled stands of such chrysanthemums as White Queen, David Ingamells, Framfield Early White, and D. B. Crane. Smaller early varieties and good bunches of amellus varieties of perennial asters made an excellent ground work. A very bright group of chrysanthemums, perennial asters, solidagos, phloxes, etc., was put up by Messrs.

W. Wells and Co., below the Royal Box; These subjects were well displayed around a central group of White Queen chrysanthemums, and at one end of the exhibit perpetual carnations figured largely.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, presented a collection of Michaelmas daisies, and, as usual, put up a charming exhibit. A few vases of a fine early white Japanese chrysanthemum named White Queen stood out splendidly among the other flowers, as also did a central batch of this variety growing in 32-sized pots. Delight, Edwin Beckett, Star Shower, Gaiety, and ericoides were very pretty among the graceful small-flowered perennial asters.

Messrs. W. Seabrook and Sons, Chelmsford, contributed a very handsome set of apples and pears, and put up fine specimens in a most tempting fashion. Of special interest were the baskets of The Queen, Blenheim Orange, Cox's Orange Pippin, Newton Wonder, Lord Suffield, Fearn's Pippin, and Ribston Pippin, while among pears Beurre Hardy, Dr. Jules Guyot, Emile d'Heyst, and Souv. de Congrès were notably good.

Mr. Brazier, of Caterham Valley, presented a collection of perennial asters and plants of the fragrant Clematis paniculata. Hardy shrubs and fruit came from Mr. D. Russell, Brentwood, and a set of collarette dahlias from Mr. J. B. Riding, Chingford, attracted a good deal of attention.

Messrs. James Carter and Co., Raynes Park, put up a temple-like exhibit of pæony and cactus dahlias and a collection of dwarfed trees, while, in front of the orchestra, Messrs. J. Cheal and Sons set up sprays of coloured foliage, among which the acers, prunus, koelreuteria, cratægus, rhus, pyrus, and oaks were particularly brilliant.

Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow, showed a good set of bunches of early chrysanthemums suitable for market; Moneymaker, Cranford Pink, Cranford Yellow, Roi des Blancs, H. W. Thorpe, and Tom Edwards were specially notable.

MEDALS.

Gold.—Mr. Norman Davis, Framfield, Sussex.

Small Gold.—Messrs. W. Wells and Co., Merstham; Mr. H. J. Jones, Lewisham.

Silver-gilt.—Messrs. W. Seabrook and Sons, Chelmsford (fruit); Messrs. James Carter and Co., Raynes Park (dahlias and dwarfed trees).

Large Silver.—Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow; Messrs. J. Cheal and Sons, Crawley (autumn foliage); Mr. David Russell, Brentwood (hardy shrubs); Mr. J. Brazier, Caterham (Michaelmas daisies).

Silver.—Mr. J. B. Riding, Chingford, (dahlias).

Bristol and District Gardeners' Mutual Improvement Association.

At the monthly meeting held on September 28 at St. John's Parish Rooms, a good attendance gathered to hear a lecture by Mr. Biss, from the Bath Gardeners' Debating Society. The subject was the "Winter Moth." He gave a very interesting lecture, and described the winter moth in the various stages of its life history. He strongly advised grease bands to be put round all fruit trees to catch the female moth as the only means by which it can, unaided, reach the branches to lay its eggs is by crawling up the trunk. The males are provided with wings, but many of them are also caught on the grease bands. He advised all fruit growers to try their best to exterminate these pests, and not leave it to a few only, and he expressed the wish that an Act of Parliament would render it compulsory on the part of all fruit growers to do their part in this matter. He explained the difference between the codlin and the winter moth; both females are wingless, but when the caterpillars of the codlin are developed they eat their way to the core of the apples, then the fruits fall, and if they are not picked up the caterpillars escape. The caterpillar of the winter moth eats its way out, and lets itself down with a thread. Mr. Biss maintained that the British fruit growers lost quite half of their fruit crop from the ravages of the larvæ of the winter moth, and yet do nothing to help themselves. A good discussion followed.

For three bunches of perennials Messrs. Binfield, Scott, and Springham were placed in the order given. Mr. Jennings was awarded four points for Oncidium varicosum Rogersi. Mr. Springham five points for a fine dish of culinary peas.

METEOROLOGICAL OBSERVATIONS.

FORTHCOMING ENGAGEMENTS.

MONDAY, October 9.—United Horticultural Benefit and Provident Society: Committee Meeting.

TUESDAY, October 10.—Royal Horticultural Society's Fruit Show: two days. There will be no general exhibition or lecture, but the Standing Committees will meet at 12 o'clock to consider novelties.

International Horticultural Exhibition 1912: Meeting of Surrey Committee at Hotel Windsor, 12 noon.

Horticultural Club, Hotel Windsor, Westminster; dinner at 6 o'clock, to be followed by a lecture on "Rhododendrons" by Mr. C. P. Raffill, of Kew.

WEDNESDAY, October 11.—Annual Conference of Delegates from affiliated Societies, at Royal Horticultural Hall, 3 p.m.

THURSDAY, October 12.—National Horticultural Society of France (Paris).

WEDNESDAY, October 18.—North of England Horticultural Society, at Leeds.

MONDAY, October 23.—National Chrysanthemum Society; Floral Committee at 3 o'clock at Essex Hall, Strand; General Committee at 7 o'clock at Carr's Restaurant, Strand.

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price **10/6**. Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).

ANSWERS TO CORRESPONDENTS.

CHINESE PRIMULAS.—K. M. B., Durham: There seems to be no weak point in the methods you adopt for the production of Chinese Primulas to bloom about Christmas and the New Year. Local conditions do very often have a very marked and curious influence upon plants, and it is a matter of common knowledge that until such conditions are fully understood and allowed for, certain plants grown with the utmost ease in one garden are more or less a failure in a garden but a short distance away. In your case we can only suggest a few points for consideration. Sow the seeds a fortnight later in future; prick out and pot off the seedlings directly they are large enough, because if the young plants suffer ever so little from lack of food and moisture, they never completely recover from the check, and such check has a tendency to produce early and unsatisfactory flowering. If special attention is paid to the drainage of the pots, you may very well dispense with peat and charcoal in the compost used at the final potting, increasing the amount of loam, and, if the latter is not of the very best quality, adding a little dried cow manure or old hot-bed manure.

H.T. ROSE RICHMOND.—M. E. J., Dorking: This beautiful rose was first distributed in America, in 1905, so that it is in no sense an old variety. Its parents were Lady Battersea and General Jacqueminot. It is a first-rate garden rose, but flowers so freely that in many places, especially on light soils, it appears to exhaust itself, hence it is sometimes regarded as lacking in constitution. A good deep rich loam suits it best, and even under these conditions the plants do not retain their vigour for many years. On light soils, and in positions where the atmosphere is rather dry, the occasional renewal of stock is necessary.

FUNGUS ON TREE ROOTS. — F. S. E., Lynn: The conifer roots have been subjected to expert investigation, and found to be suffering from the attack of a very common British toadstool, a fungus named Armillaria mellea. Wherever this appears, although it may seem to rise from the soil alone, close examination will show that roots of trees or buried wood are the point of origin. The fungus is capable of doing a vast amount of damage, hence, whenever it is found, great care should be taken to collect and burn the specimens, and thus reduce the possibility of infection. Any damage to the base of the trunk or the partly-exposed roots of lawn or orchard trees, due to mowing, hoeing, etc., should be carefully avoided, as it is by means of such wounds that the fungus finds a ready means of entrance; from the roots the mycelium passes up the base of the trunk, attacking the young wood, the cambium layer, and the bark, and as at this point the attack is made over the entire circumference of the stem, the tree soon dies. It is impossible to save a tree that is already in a state of collapse, but whenever a tree is known to be attacked, it should be at once isolated by means of a trench cut some distance from the trunk, so as to prevent the fungus from passing along to the roots of neighbouring trees. In the case of a lawn specimen that dies from the disease, every part should be burned, and special care should be taken to follow up, remove, and burn all its roots.

BRUSSELS SPROUTS IN CABBAGE CROP.—R. A., Keighley: The presence of some Brussels sprout plants among your cabbages may be due to one of several causes. If the seed beds were close together a few seeds of sprouts may have fallen during sowing upon the cabbage bed; plants from the extreme edges of adjacent seed beds may have been carelessly pulled up together, and so become mixed; a few seeds of the one crop may have become mixed accidentally with the bulk of the other; and then there is the possibility of seed crops having been grown too near each other, though this is a remote one, as all seed growers know the tendency of cabbage crops to cross-fertilise if growing near one another, and they guard against it. We fancy the trouble arises in your own garden.

NAMES OF PLANTS.

E. C. F., Chichester.—Ilex dipyrena.

L. C., Bromley.—1, Mussænda frondosa; 2, Ipomæa Horsfalliæ.

B. J., Whitchurch.—1, Coreopsis grandiflora; 2. Rhus Cotinus.

A. D., Cardiff.—1, Diplopappus chrysophyllus; 2, Retinospora obtusa.

N. L. M., Lymington.—1, Odontoglossum ardentissimum; 2, Oncidium varicosum Rogersi; 3, Cattleya Harrisonæ.

L. C. H., Sunbury.—1, Dracæna Godseffiana; 2, Thyrsacanthus rutilans; 3, not recognised, send when in flower; 4, Impatiens Roylei.

NAMES OF FRUITS.

G. B., Dublin.—Your pear is Marie Louise.

H. B., Chester.—1, Bess Pool; 2, Tyler's Kernel.

G. O., Stoke-on-Trent.—1, Hollandbury; 2 and 3, not recognised; 4, Rosemary Russet,

D. W., Hugglescote.—Uvedale's St. Germain—a stewing and baking pear, very fine specimen.

F. M. B., Ipswich.—1, Cox's Orange Pippin; 2, Catillac; 3, not recognised; 4, Blenheim Pippin.

D. R. S., St. Albans.—1, Adam's Pearmain; 2, Roundway Magnum Bonum; 3, Mère de Ménage.

A. P. U., Sussex.—1, Brabant Bellefleur; 2, Bismarck; 3, not recognised; 4, Rymer; 5, Norfolk Beefing; 6, Bedfordshire Foundling.

C. N., Essex.—2, Beurre Gris d'Hiver; 3, not recognised; 4, Gold Medal; 5, Sheepsnose; 6, Beauty of Bath; 7, Doyenne du Comice.

T. H., South Devon.—1, Ecklinville; 2, Souvenir du Congrès; 3, Figue de Naples; 4, Bergamot; 5, not recognised: 6, Doyenne Boussoch.

M. H., Sherborne. — 1, Lane's Prince Albert; 2, Baumann's Winter Reinette; 3, Golden Noble; 4, small specimen, probably The Queen.

J. S., Faringdon.—The specimens were so small and scabby, and consequently altogether out of character, that they could not be identified.

R. U., Maldon. — Unfortunately in the course of transmission through the post, the numbers became separated from the specimens. We are therefore unable to give the names.

J. H., Woolton.—1, Bellissime d'Hiver; 2, Broom Park; 3, Beurre Gris d'Hiver; 4, Des Deux Sœurs; 5, 11, and 13, Beurre Diel; 6, 8, 12, and 17, Marie Louise; 7 and 15, not recognised; 9, Zephirin Gregoire; 10, Beurre de Capiaumont; 14, Baronne de Mello; 16, Thompson's; 18, Belle Julie; 19, Swan's Egg.

OBITUARY.

◆

MR. WILLIAM EARLEY.

It is with deep regret we have to announce the death, at Croydon, on Wednesday, September 27, of Mr. William Earley. Mr. Earley reached his seventy-sixth birthday the day previous to his death. Until within the last ten years he was a prominent figure in horticultural circles, especially in the London district, where his wide knowledge, genial character, and goodly presence made him very well known. Despite his father's efforts to the contrary, Mr. Earley made gardening his life work, and, after service in numerous establishments, he had charge of the gardens at Digswell House, Welwyn, and subsequently was head gardener at Valentine's, Ilford, a place famous for its very old Black Hamburgh vine, which is supposed to have been the parent of the even more famous great vine at Hampton Court.

Until increasing age rendered the reduction of work imperative, Mr. Wm. Earley was a regular contributor to the Gardeners' Magazine. Many years ago Mr. Earley edited a sixpenny monthly journal, entitled "The Villa Gardener," and he also edited a penny weekly gardening paper, which, if memory serves us rightly, was known as "The Horticultural Record." Our old friend had a happy knack of redeeming the lowlier matters of horticulture far above the common place, and he would find subjects of interest where most people saw nothing worth recording.

After retiring from the charge of gardens, Mr. Earley acted as horticultural adviser, and his services were much in request for the construction of new and the improvement of old gardens. As a judge he was well known, and here again his wonderfully genial manner won him many friends even among those who failed to win prizes under his judgment.

To the general public Mr. W. Earley was best known through the medium of "Lloyd's Weekly News," to which paper he had regularly contributed the weekly "Gardening Notes," over a period of nearly forty years. As a contributor of the "Gardening Notes" to "Lloyd's" he succeeded that famous old florist, George Glenny, and continued to occupy that position until the time of his death, his last contribution appearing in the issue of that journal for October 1.

SURREY GROWN SWEET PEAS.

BERTHA MASSEY.

(First in Novelty Class—National Sweet Pea Society, 1911.)

This variety is a distinct break, being quite a new art shade of pale mauvy-lilac, fine Spencer form. Is absolutely fixed, a very strong grower, and is fine for exhibition or for garden decoration. Repertoire de Coleurs, 186 to 187, No. 1. 12 seeds, 1s.

BLUE BELLE.

A most attractive pea of the grandiflora type. Standard opens purplish-mauve, passing to blue, the finished flower being a very pleasing bright blue. Repertoire de Coleurs, standard opens, 186 No. 2; wings, 202, No. 4. 20 seeds, 6d.

ORANGE KING.

A bright deep salmon self of the grandiflora type. Needs good culture and slight shading from the sun's rays. It is undoubtedly the brightest and deepest salmon or orange pea extant. Repertoire de Coleurs, 74, No. 4. 12 seeds, 6d.

MRS. STEWART CHAMPION.

A giant among sweet peas, true Spencer form, cream ground, overlaid soft rosy-pink. A strong grower, producing mostly three, but sometimes four, flowers on a stem. Is quite fixed, and is altogether a fine introduction. Repertoire de Coleurs, 118, No. 1. 12 seeds, 1s.

The following is a list of special varieties extracted from our handy pocket list:—

	Seeds.	Price.
Arthur Unwin, the finest bicolor	20	4d.
Betty Cantley, pale salmon-apricot	15	4d.
Constance Oliver, bright pink	25	3d.
Clara Curtis, deep primrose, true certificated stock	25	4d.
Elsie Herbert, giant-flowered blush	30	3d.
Edna Harland, carmine-pink Countess Spencer	15	4d.
Edrom Beauty, re-selected Helen Lewis, very fine	20	4d.
Edna Unwin, glowing orange-scarlet	20	4d.
Eric Harvey, white ground, bright rosy-pink edge	10	6d.
Etta Dyke, beautifully waved white	25	3d.
Flora Norton Spencer, lovely waved sky-blue	25	3d.
Florence Nightingale, the best waved lavender	20	4d.
Giant Cream Waved, one of the finest waved primrose peas	20	4d.
Gladys Burt, lovely pale pink	20	4d.
Helen Grosvenor, bright shining orange-pink	20	6d.
Mrs. Townsend, white ground, violet edges	20	4d.
Mrs. Hardcastle Sykes, one of the best very pale pinks	40	3d.
Maud Holmes, giant deep crimson	20	4d.
Mrs. C. W. Breadmore, cream ground, edged pink	25	3d.
Mrs. W. J. Unwin, white ground, flaked orange-scarlet	10	6d.
Masterpiece, waved lavender	20	4d.
May Farquhar, Spencer form of Lord Nelson	15	6d.
Mrs. R. H. Carrad, rosy-lilac	15	6d.
Mrs. Hugh Dickson, beautiful cream-pink ...	20	4d.
Nubian, the finest maroon	10	6d.
Nettie Jenkins, lovely pale lavender	15	6d.
Paradise Ivory, ivory-white, very strong grower	25	3d.
Sunproof King, grand, deep crimson, waved	20	4d.
Scarlet Monarch, lovely bright waved scarlet	10	6d.
Tennant Spencer, deep mauve	25	2d.
Thomas Stevenson, the finest orange-scarlet waved	15	6d.
Zero, the earliest-flowering waved pea ...	25	2d.

The Novelties are nett prices as quoted. All varieties in general list subject to a cash discount of 20 per cent., 4s. in the £, for 2s. 6d. value and over. Carriage and postage free on all orders 1s. and upwards.

The quality and fixity of our Sweet Peas cannot be beaten.

Capt. ———, Londonderry.
10th February, 1911.

"I have received your Horticultural Manual, and on looking through it, I felt compelled to write and thank you for it. To an enthusiastic amateur gardener like myself, who, through reading the weekly papers on the subject, is familiar with many of the names but not with the corresponding flowers, this book must be absolutely invaluable, and the artistic way in which it is got up, and the beautiful photographs with which it is embellished, make it a treasure well worth having. I have had the Catalogues of most of the leading firms sent to me, but nothing compares in the remotest way with yours."

MY SWEET PEA LIST

will be the most time-saving, interesting, profitable, and pleasure-giving list in the world. Post-card commands it.

I am being honoured with **novelties** from Aitken's, Chapman, Cole, Burpee, Deal, Dobbies, Hemus, Lumley, Stark, Trevethick, Ward, and many others.

My stock of last year's novelties are, with few exceptions, English grown and rogued by **genuine Sweet Pea lovers.**

My Special Spencer Mixture contains Earl Spencer, Nancy Perkin, Syeira Lee, Thomas Stevenson, Dainty, and Helen Pierce Spencers, etc. This I **guarantee. 1s.** per oz., **1s. 10d.** per 2oz., **3s. 6d.** per 4oz., post free.

My Helen Pierce Spencer Seedlings will be a source of profit and pleasure to the grower. The stock has been rogued down to Spencers at great expense. A selection from this mixture properly fixed will make a small fortune for the owner. **1s. 6d.** per oz., **2s. 6d.** per 2oz., post free.

My Special Seedling Spencer Hybrid Mixture is from two of our keenest British hybridists, who have more stock than they can possibly handle as it ought to be. **Such seed never offered before. 1s. 6d.** per oz., 2oz. for **2s. 6d.**, post free, worth 10s. per oz., as it is absolutely the result of their life's work. Virtually selling proverbial £1 for one penny.

Sole distributing agent for Mr. F. Herbert Chapman's Iolanthe, the most opaque white Sweet Pea in existence. 8 seeds, **6d.**; 20 seeds, **1s.**

I hope to have my list ready early in October.

G. H. MACKERETH,
The Sweet Pea Clearing House, ULVERSTON.

Orchids! Orchids!! Orchids!!!

The undersigned begs to announce to the Public that he is in a position to supply, wholesale or retail, **Burma Orchids** of 50 varieties at a moderate price. Further particulars on application.—**J. C. PRAZER, Orchid Collector, KALEWA, BURMA.**

N.B.—Please register orders early for Dendrobium Nobile, thick-bulbed variety; Dendrobium Jamesianum, Dendrobium Bensoni, Renanthera imschootiana, Vanda Cœrulea Lushai Hill variety, dark blue type; Cypripedium spicerianums of five and six growths, as these are scarce and expensive collecting.

FREEHOLD RESIDENCE, modern, three reception, 5 bed-rooms, boudoir, kitchen and scullery; splendid grounds, 10 acres; 7 greenhouses, stabling, cowsheds, calf-shed; every convenience and comfort; choice fruits and large orchard. H. THOMLINSON, Four Marks, Alton.

Flowers all the Year.

Now is the time to plant Kelway's Artistic Colour Borders to secure a profusion of rich, many-hued bloom throughout the year from early spring to late autumn. These borders, which can be planned to fill any space, are composed of the famous Kelway Pæonies, Delphiniums, Pyrethrums, Gaillardias, and other hardy herbaceous plants, and they thrive well, with a minimum of attention, in almost any soil.

NOW is the Time to Plant.

The cost is **15/-** or **25/-** for 10 square yards, according to selection. The plants are labelled and numbered in order of planting.

KELWAY and SON,
The Royal Horticulturists,
LANGPORT, SOMERSET.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

◆

Fruit Trees in the Flower Garden.

While strongly advocating the planting on a liberal scale in the flower garden and pleasure grounds the finest of the trees remarkable for the beauty of their flowers, we have not at any time lost sight of the attractiveness in their season of blossoming of many of the fruit trees that are held in high estimation for their economic value. We have, indeed, on more than one occasion called attention to the charms of apple, cherry, pear and plum trees when enwreathed in their delicately-tinted or snowy-white flowers, and suggested that in many gardens some at least of them might with advantage be assigned positions in those parts where beauty rather than usefulness has first consideration. Within recent years our views on this aspect of fruit growing have been considerably strengthened, and, as the result of widely-extended observations, we are fully convinced that in gardens well-nigh innumerable fruit trees might with advantage be planted for the dual purpose of enhancing their charms in spring and contributing to the fruit supplies during the summer and autumn, and indeed to those of the winter also. While having no doubt as to the desirability, in many instances, of planting in the flower garden fruit trees that possess a high degree of utility, we regard the question associated therewith as one that should have the most careful consideration. It is not sufficient to say that because the beauty of the flowers of certain fruit-bearing trees is great, the trees should therefore be selected for the flower garden instead of those of kinds that are now being planted in large numbers for the production of colour effects. It is, for instance, advisable to take into account the difference between the great garden wherein there is ample space for placing each of the several classes of subjects that come under the gardener's care, in the positions most conducive to their attaining to a high state of development. There could not well be any objection to the arrangement in moderate numbers of groups of fruit trees in the pleasure grounds of large extent. On the contrary, they will add to their attractions and interest provided they are grouped with due regard to tasteful effect. But they ought not to be planted in such large proportions in relation to the other trees with which they will be associated as would be admissible, and indeed be advisable in gardens of moderate dimensions. From no garden, whatever its size, do we desire to see the magnolias, the scarlet chestnuts, the laburnums, the thorns, the amelanchiers, or the lilacs, which, although properly classed with the shrubs, may be grown into trees if so desired, wholly banished for the purpose of providing space for apple, cherry, pear, and other fruit trees. These kinds may be appreciably reduced in the smaller gardens, but in few of the larger ones will there be an occasion for reduction, as in most cases there will be no difficulty in providing room for a few groups of fruit trees. With regard to the relative merits of the ornamental kinds and those grown for their fruit, there is really no great difference in the attractiveness when in bloom of the apple trees and the ornamental crabs, but in effectiveness the double-flowered cherries are much superior to those grown for their fruits, beautiful as they unquestionably are. In the case of the pears and plums it is not possible to institute comparisons that would have any practical value, and the useful kinds of these fruits may be planted with the assurance that they are at least equal in beauty in their season of flowering to those which have no value as fruit bearers. In turning from a general consideration of the case in favour of the growth of fruit trees in the flower garden, to its bearing on the interest and usefulness resulting from the practice in gardens of moderate dimensions, much might be written in advocacy thereof. There is, however, no occasion to labour this point, but attention may be directed to the fact that the blossom of such apples as Blenheim Pippin, Golden Noble, Lane's Prince Albert, and Worcester Pearmain, to take a few at random, is not less beautiful than that of the species and varieties of Pyrus which have obtained much favour. There is no great difference, if any, in the length of the period over which the respective seasons of flowering extend, but the apples have an advantage, as in the majority of seasons the flowers will be followed by fruits which will give rise to more or less interest in the process of development, and it may be take on colouring, as in the case of Scarlet Pearmain, sufficiently bright to convert the trees into objects of great beauty. If the owner of a garden has an objection to apple trees in his flower borders or on the lawn, it is open to him to take a middle course, and plant such crabs as the Dartmouth, John Downie, and Transcendent, which are elegant in habit, profuse in flowering, and bear, in favourable seasons, an abundance of fruits that are remarkable for their brilliant colouring; and in the autumn the leaves take on tints of great beauty. The fruits of these crabs are useful as well as beautiful, as when ripe they are equally suitable for

MR. W. SEABROOK.

conversion into jelly and preserving whole. There is probably no object more beautiful than a cherry tree cultivated for its fruit when enwreathed in its snowy blossoms, but the flowers retain their freshness and beauty for a short period as compared with the double flowers of the ornamental kinds, whether of British or Japanese origin. But, as in the case of the apples, the flowers are followed by a crop of fruits which, if it escapes the birds that appreciate the rich flavour of cherries, will be attractive when ripening and useful when that process is completed. It is advisable not to plant cherry trees other than in limited numbers, for the blackbirds and thrushes are so partial to the fruits that they commence their attacks immediately they begin to change colour, and it is difficult to resort to protective measures on a large scale without some disfigurement of the flower garden. The Morello is the best kind for lawn planting, for the tree has an elegant habit, and the birds do not commence their attacks upon the crop at so early a stage as they do upon the sweet cherries. Usually very little damage is done until the Morellos are ripe enough for bottling and other purposes in the kitchen, and if gathered immediately on reaching this stage there will be no great loss. Pears and plums are attractive when in bloom, and of interest throughout the summer, and require no special reference except to say that the latter are the most profitable. In the selection of varieties and methods of planting the same course of procedure should be followed as in forming plantations in other parts of the garden, but an endeavour should be made to so arrange the trees as to produce a somewhat natural and picturesque effect.

Mr. W. Seabrook, the founder of the firm of W. Seabrook and Sons, The Nurseries, Chelmsford, has devoted many years of his life to the subject of dwarfing stocks for fruit trees. About thirty-five years ago he started experiments in the selection of paradise stocks for apples, and succeeded in securing a strain that produces excellent results. He was one of the first to anticipate the modern methods of fruit growing, which the paradise stock subsequently brought about. At that time the system of dwarf, quick-fruiting trees was in its infancy, as regards the market grower, at any rate, and orchards of dwarf trees were practically unknown. At the present time all the keenest growers are planting up dwarf trees. Mr. Seabrook was one of the first fruit growers to pack and grade the finest selected fruit in single layer boxes for Covent Garden, he having early realised that enhanced prices could be obtained by attractive packing and careful grading. For five or six years his firm has exported apples to the Colonies and other countries in yearly increasing quantities, the packing and grading being done on the Australian and Californian systems. The Home Nurseries at Chelmsford contain the experimental department, and here the questions of insecticides, fungicides, and manures have been studied for many years. Mr. Seabrook has always been one of the strongest advocates of spraying. During the last few years the nurseries have been greatly enlarged, and now comprise over sixty acres. Large areas are planted with cordon trees of Cox's Orange Pippin and other sorts of apples, and these are a feature of the place; this form of tree is greatly favoured by Mr. Seabrook, not only as being almost indispensable to the private gardener, but also for the production of first-grade fruit for market. Remembering the fine fruit shown, and splendid exhibits made by the Chelmsford firm, our readers will understand that Mr. Seabrook is an enthusiastic believer in an excellent future for fruit growing in this country.

"Gardeners' Magazine" Rose Number.—To fully meet the large and ever-increasing demand at this season of the year for information on the selection and planting of roses, we shall devote the issue for the 21st inst. chiefly to roses and rose culture. The contents will have special reference to the work requiring attention at this season of the year, and will include articles on "The Newer Roses," "Roses for Forcing," "Rampant Climbing Roses," "The Best Twelve Wichuraianas," "Preparation of Rose Beds," "How and When to Feed Roses," "Roses for House Walls," and "Grouping Roses."

The Times Experimental Station.—We have much pleasure in announcing that Mr. Harry Foster, son of the late Mr. Charles Foster, has been appointed director of the Times Experimental Station, Sutton Green, Guildford, and that he assumed full control of the important work on October 1. The protracted illness of the late Mr. Charles Foster threw the burden of responsibility on the shoulders of his younger son, and he acquitted himself with all credit. In addition to the general work of the station the trials of sweet peas for the National Sweet Pea Society and of vegetables for the National Vegetable Society, were conducted with marked skill and accuracy, and received the unanimous approbation of the committees and members of those bodies. Mr. Harry Foster completed his education at the Reading Collegiate School, subsequently gaining valuable scientific knowledge under Mr. F. J. Chittenden at Wisley, and practical experience under his late father at the station to the directorate of which he is now called. The high esteem and respect in which his late father was held will ensure for the son a welcome into horticultural circles, and a general wish that he may achieve a full measure of success in the discharge of his important duties.

Roses at the Coronation Exhibition.—As we have already stated in these pages, roses constituted a glorious feature throughout the summer months at the Coronation Exhibition, and the magnificent rose garden formed by Messrs. William Paul and Son, Waltham Cross, Herts, proved an immense attraction, and was regarded as a triumph in outdoor rose culture. Not so long since we had the pleasure of illustrating a portion of this beautiful garden. We therefore have much pleasure in stating that the firm have received a Diploma for Grand Prize from the Council of the exhibition.

First Congress on Small Holdings.—A committee associated with the Festival of Empire, Crystal Palace is for the first time bringing together a congress of those interested in agricultural matters, particularly as connected with small holdings. The congress is to be of a non-political character, and its deliberations are being devised upon the broadest lines. The opening of the congress is fixed for October 18, when Lord Carrington, the President of the Board of Agriculture, will deliver the inaugural address. The deliberations of the congress will extend over October 19 and 20. Subjects for discussion have been arranged in the following order: Opening Day.—Lord Carrington's address and a discussion upon "Credit, as Applied to Small Holdings"; October 19, "Production and Co-operation," "Marketing and Transportation"; October 20, Morning.—"Equipment of Small Holdings"; afternoon.—"Education from the Small Holders' Standpoint." The details of this congress have been delegated to a committee, of which Mr. R. A. Sanders, M.P., is chairman, and Mr. G. Montagu Harris, secretary of the County Councils' Association, is vice-chairman. Mr. W. H. Jones, Festival of Empire, Crystal Palace, is secretary to the congress.

"**R.H.S. Journal.**"—The first part of Vol. XXXVII. of the Royal Horticultural Society's "Journal" has been issued, and contains much that is of interest to horticulturists. The contents include summaries of the two Masters' Lectures given by Mr. G. F. Scott Elliot, one on "Single Seed Selection," and the other on the "Changing of Species," and papers on "Electricity in Relation to Horticulture," "Plants of Chatham Island," "Alpine Plants in their Native Haunts," "Alpine Gardens," and the "Origin and Structure of Aquatic Flowering Plants." Mr. E. A. Bunyard contributes an index to the illustrations of apples that have been published in the older pomological works. It is remarkably well done, and should prove useful to those who devote some share of their attention to the historical aspects of fruit culture.

Trial of Decorative Dahlias.—During the past season Messrs. H. Cannell and Sons, with a view to assist the National Dahlia Society in its endeavour to bring into prominence the dahlias especially adapted to garden decoration, conducted a comprehensive trial of decorative varieties in their home nurseries at Swanley. On the 5th inst. the executive committee visited the trials for the purpose of selecting the varieties of special excellence for the garden. Notwithstanding the unsatisfactory character of the past season, the whole collection of dahlias was found in a most satisfactory condition, and the heartiest thanks were accorded to Messrs. H. Cannell and Sons for their assistance in the preparation and cultivation of the plants under trial. Three marks of distinction were given to the following varieties for their effectiveness in the garden: Collarettes—Negro, Mad. Porrier, Mr. E. D. Till, Mons. Hugonard, A. Normene, H. Tarne, and Souv. de Chaubanne. Decorative—Kaiserin Augusta Victoria. Giant Decorative—Phenomané, Ethel May, Le Grand Manitou, F. Grinsted, Papa Charmet, and Gloire Lyonaise. Giant Single—Mrs. W. C. Jackson, White Cloud, and Evelyn Jackson. Pæony-flowered—Geisha, South Pole, Golden West, Glenton, Dr. Hogg, and Madame J. Coissard. Garden Cactus—Amos Perry and Effective.

Dinner to a Scottish Gardener.—On a recent evening Mr. Young, who has during the past three years occupied the post of gardener to the directors of the Crichton Royal Institution, Dumfries, and is leaving to take up an Irish appointment, was entertained at dinner by his brother gardeners and personal friends. There was a large attendance, presided over in a genial manner by Mr. J. Hutchison, Terregles, Gardens, Dumfries. During the evening, the Chairman proposed the health of Mr. Young, and presented him, on behalf of the company, with a smoker's companion as a memento of the function. Mr. Hutchison referred in fitting terms to Mr. Young's good qualities as a gardener and as a man, and assured him that the good wishes of many would go with him in his new appointment. Mr. Young made a suitable reply.

GREAT EXHIBITION OF BRITISH-GROWN FRUIT.

Some of the earlier exhibitions of British-grown fruit held under the auspices of the Royal Horticultural Society may have been more extensive than the one held on October 10 and 11, but we believe none was ever better than this in the matter of high quality.

The apples were superb in size, colour, and finish, and there was a marked absence of inferior and spotted examples; pears left little to be desired, and grapes were present in numbers and quality far ahead of anything seen for many years. The competition in trade and general classes was excellent, and everyone who took part in the provision and management of the display is deserving of congratulation.

COLLECTIONS OF DESSERT FRUIT.

The opening class in the schedule was for nine dishes of ripe dessert fruits, and here the premier award was a silver cup and £5. There were five entries, and Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, came first with large clusters of Muscat of Alexandria and Alicante grapes, and fine dishes of Golden Eagle and Princess of Wales peaches, Pitmaston Duchess and Doyenne du Comice pears, Cox's Orange Pippin apples, and Victoria nectarines; second award fell to Mr. S. Barker, gardener to the Duke of Newcastle, Clumber, Worksop, whose Madresfield Court grapes, Doyenne du Comice and Emile d'Heyst pears, and Ribston Pippin apples were very good; Mr. C. A. Cain, gardener to T. Pateman, Esq., Node Gardens, Welwyn, third.

Mr. J. Kidd, gardener to G. Meller, Esq., Newberries, Radlett, was awarded first prize for a good set of six dishes, consisting of large bunches of Alicante and Muscat of Alexandria grapes, Cox's Orange Pippin, and Ribston Pippin apples, Pitmaston Duchess pears, and The Countess melon. Mr. Prime, gardener to the Marquis of Salisbury, Hatfield House, Herts, second, and Mr. J. Vert, gardener to Lord Howard de Walden, Saffron Walden, third.

GRAPES.

There were three entries of five varieties of grapes, two bunches of each, and the veteran grower, Mr. J. H. Goodacre, secured the silver cup and first prize with nicely finished clusters of Muscat of Alexandria, Madresfield Court, Alicante, Muscat Hamburgh, and Chasselas Napoleon; Mr. S. Barker, Clumber Gardens, came second with very heavy bunches of Barbarossa, and neat, well-coloured examples of Madresfield Court, etc.; there were only two prizes offered, so Mr. J. Kidd's set of grapes received no recognition.

For four varieties of grapes, selected from a specified list, two bunches of each, Mr. J. Shelton, gardener to Lord Hillingdon, Wildernesse, Sevenoaks, was the only exhibitor, and he was awarded first prize for Muscat of Alexandria, most beautifully golden coloured; Muscat Hamburgh, Madresfield Court, and Mrs. Pince.

Mr. J. Shelton led for a pair of bunches of Black Hamburgh, with large-berried clusters; Mr. A. Heald, gardener to Rev. W. Becker, Wellow Hall, Newark, second, and Mr. J. H. Goodacre, third. Mr. J. Doe, gardener to Lord Savile, Rufford Abbey, Ollerton, led for Mrs. Pince, with large, long clusters; Mr. C. Earl, gardener to O. E. d'Avigdor Goldsmid, Esq., Tonbridge, Kent, second; five entries.

In the class for a pair of bunches of Alicante grapes there were ten entries; Mr. J. Kidd was first with wide-shouldered clusters; Mr. K. H. Smith, gardened to W. James, Esq., West Dean Park, Chichester, second; and Mr. C. L. Branson, gardener to G. Hanbury, Esq., Hitcham, Maidenhead, third. Madresfield Court was staged by five competitors; Mr. Goodacre was first prize-winner with very large-berried bunches; Mr. S. Barker second, and Mr. Shelton third.

Mr. J. Doe led for Prince of Wales, from four competitors, with wonderfully fine bunches of big plum-like berries, deeply coloured; Mr. J. C. Sutton, gardener to Earl Stanhope, Chevening, Sevenoaks, second. For "any other black grape" Mr. Goodacre scored with Muscat Hamburgh, among eight entrants; Mr. J. Kidd second with Appley Towers. In the class for Muscat of Alexandria grapes there were six competitors, and the awards fell in order to Mr. C. Earl, and Mr. W. Lane, gardener to Sir E. Durning Lawrence, Bart., King's Ride, Ascot. For "any other white" variety Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham, led with Dr. Hogg; Mr. S. Barker was second with Buckland Sweetwater; and Mr. Pike, gardener to H. W. Henderson, Esq., King's Langley, second with Foster's Seedling.

APPLE LORD SUFFIELD.
A fine dish of this free-bearing culinary apple, exhibited by Messrs. W. Seabrook and Sons, Lim., at the R.H.S. Fruit Show.

COLLECTIONS OF APPLES.

Six competitors came forward in the class for two dozen dishes of apples, sixteen culinary and eight dessert varieties. Premier honours fell to Mr. J. Whittle, gardener to Colonel Borton, Cheveney, Hunton, Kent, who had a marvellously fine set of full-sized, clean, and beautifully-coloured fruits of Bismarck, Lord Derby, Mère de Ménage, Peasgood's Nonsuch, Newton Wonder, Warner's King, Emperor Alexander, Belle Pontoise, Golden Noble, Alfriston, Lane's Prince Albert, Bramley's Seedling, Annie Elizabeth, Belle Dubois, Gascoigne's Scarlet, Lady Henniker, Allington Pippin, American Mother, King of Tompkins County, Wealthy, King of the Pippins, Melon Apple, Cox's Orange Pippin, and Charles Ross. We doubt much whether there has ever been quite as fine a set, considering quality, colour, and size, ever staged before. Second prize fell to Mr. W. H. Bacon, gardener to Sir Marcus Samuel, Maidstone. Mr. R. Alderman, gardener to C. R. Adriane, Babraham, Cambridge, was placed third with a very clean set of bright even-sized fruits; Mr. Henry Whiteley, St. Mary Church, Torquay, was awarded an equal third prize as he had a splendid set of dessert varieties, notably Charles Ross, Houblon, Coronation, and Cox's Orange Pippin, though his culinary sorts were not very large. Mr. A. Carlisle, Biggleswade, was given an extra prize; he failed to show quite in accordance with the schedule, having included Blenheim Orange as a culinary variety, whereas, according to the R.H.S., it must be classed as a dessert variety.

For eighteen dishes of apples, distinct, a dozen of cooking and six dessert, Mr. E. A. Cain led the way, and presented excellent dishes of Peasgood's Nonsuch, Lane's Prince Albert, Newton Wonder, Bedfordshire Foundling, Cox's Orange Pippin, and Rival; Mr. F. G. Gerrish, gardener to J. G. Williams, Esq., Pendley Manor, Tring, a good second, and Mr. J. W. Barks, gardener to A. P. Brandt, Esq., Bletchingley, third.

Premier award for a dozen dishes of apples, four varieties to be suitable for dessert, was secured by Mr. F. Cornford, gardener to Major Powell Cotton, Quex Park, Thanet, with fine examples of Lady Henniker, Bramley's Seedling, Peasgood's Nonsuch, Charles Ross, and King of the Pippins; Mr. H. Learmouth, gardener to J. Liddell, Esq., Sherfeld Manor, Basingstoke, second (he had a grand dish of Peasgood's Nonsuch); and Mr. Strugnell, gardener to the Right Hon. W. H. Long, Trowbridge, third. The best collection of six dishes of culinary apples, distinct, came from Mr. J. Whittle, whose varieties, represented by very heavy fruits, were Mère de Ménage, Warner's King, Belle Dubois, Emperor Alexander, Bismarck, and Peasgood's Nonsuch; Mr. A. Carlisle, second. For six dishes of dessert fruits Mr. Whittle was well ahead among four entrants with lovely fruits of King of the Pippins, Allington Pippin, Wealthy, Rival, American Mother, and Cox's Orange Pippin; Mr. A. Carlisle second.

COLLECTIONS OF PEARS.

The leading pear class was for eighteen dishes, and the Hogg Gold Medal and £2 provided a tempting first prize, which was won by Mr. Bacon. His varieties, all splendidly staged, were Souv. du Congres, Beurre Fouqueray, Beurre Baltet Père, Marguerite Maillat, Marie Benoist, Pitmaston Duchess, Beurre Alexandre Lucas, Conference, Marie Louise d'Uccle, Beurre Bosc, Doyenne Boussoch, St. Luke, Princess, Durondeau, Doyenne du Comice, Directeur Hardy and Emile d'Heyst; Mr. Whittle had to be content with second place.

The best dozen dishes of pears were from Mr. F. Cornford, who had very clean, delicate-skinned dishes of Beurre Alexandre Lucas, Pitmaston Duchess, Duchesse d'Angoulême, Charles Ernest, Durondeau, Beurre Diel, Doyenne du Comice, Beurre Bachelier, Princess, Beurre Hardy, and Beurre Baltet Père; Mr. C. A Cain was second.

In the class for nine dishes of pears Mr. W. Strugnell led with very bright specimens of popular sorts, nicely staged on bright ampelopsis leaves; Mr. J. W. Banks second. Mr. Carlisle scored for six dishes of pears with a good set, and was followed closely by Mr. G. Mackinlay, Wrest Park Gardens, Ampthill. Mr. Strugnell was ahead for three dishes of stewing pears with Beurre Clairgeau, Catillac, and Bellisime d'Hiver; Mr. F. Cornford second.

APPLE FOSTER'S SEEDLING.

A handsome apple useful for both cooking and dessert, and free in bearing, exhibited by Messrs. G. Bunyard and Co., at the R.H.S. Fruit Show.

PLUMS.

There were a dozen good entries of three dishes of plums, and once more Mr. J. Vert scored, this time showing beautiful fruits of Coe's Violet, Coe's Golden Drop, and Primate. Mr. W. Messenger, gardener to C. H. Berners, Esq., Woolverstone Park, Ipswich, second. Mr. Whittle was awarded a first prize for three dishes of bullaces or damsons, and Mr. Gerish, gardener to J. G. Williams, Esq., Pendley Manor, Tring, led for Morello cherries.

DISTRICT COUNTY CLASSES.

In all the following classes the first prize was £1, and third-class single fare from exhibitor's nearest station, and 15s., and third-class rail fare for second prize.

In the division open to Kent growers, Mr J. Bond, gardener to W. E. S. Erle Drax, Esq., Wye, led for four dishes of culinary, and two dishes of dessert apples—this specification applied all through the section—with grand dishes of Mère de Menage, Peasgood's Nonsuch, Hambling's Seedling, Chas. Ross, Allington Pippin, and Lord Derby; Mr. B. J. Mercer, Wierton Place Gardens, Maidstone, second. In the dessert pear class, six dishes, Mr. J. Bond was prizewinner.

There were two entries of pears from the growers of Sussex, Surrey, Hants, Dorset, Somerset, Devon, and Cornwall; Mr. Turton, gardener to F. J. Digby, Esq., Sherborne Castle, Dorset, came first with splendid dishes of Durondeau, Beurre Baltet Père, etc., and Mr. A. Tidy, gardener to Chas. H. Combe, Esq., Cobham Park, Surrey, was a close second. In the apple class Mr. D. Brock, gardener to the Duke of Richmond and Gordon, Goodwood, was a capital first with splendid fruits of Royal Jubilee, Allington Pippin, etc.; Mr. J. Copp, Ferndale, Teignmouth, second; seven entries.

Mr. A. R. Allan, gardener to Lord Hillingdon, Uxbridge, scored for pears in the division open to growers in Wilts, Gloucester, Oxford, Bucks, Berks, Beds, Herts, and Middlesex; and Mr. Markham, Wrotham Park, Barnet, was second, and both had very bright clean fruits of popular sorts. For apples Mr. T. J. Finch, gardener to the Earl of Suffolk, Malmesbury, Wilts, led and he had Mère de Ménage, Peasgood's Nonsuch, Royal Jubilee, Bramley's Seedling, Cox's Orange Pippin, and Rival in good form; Mr. C. Page, gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead, second.

The next section was for growers from Essex, Suffolk, Norfolk, Cambridge, Hants, and Rutland, and in the pear class Mr. G. Davison, gardener to Colonel Petre, Westwick, Norwich, led with famous dishes of Pitmaston Duchess, Marguerite Marillat, Doyenne du Comice, Durondeau, Conference, and Emile d'Heyst; Mr. W. Messenger, Woolverstone Park Gardens, second. For apples Mr. Davison again led, and here he had big, clean, heavy fruits of Peasgood's Nonsuch, Mère de Ménage, Bramley's Seedling, Bismarck, Ribston Pippin, and Allington Pippin. Mr. A. Andrews, gardener to the Hon. W. Lowther, Campsea Ash, Suffolk, second.

In the section open to Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Staffs, Shropshire, and Cheshire, Mr. James Gibson, gardener to the Duke of Portland, Welbeck, led the way with beautiful fruits of Tyler's Kernel, Lord Derby, Peasgood's Nonsuch, Gascoyne's Scarlet, Cox's Orange, and Ribston Pippins; Mr. J. Taylor, gardener to F. Bibby, Esq., Hardwicke, Shrewsbury, was second. For pears Mr. Gibson was easily first with heavy specimens of Beurre Diel, Marie Benoist, Pitmaston Duchess, Doyenne du Comice, Emile d'Heyst, and Chas. Ernest; Mr. Bibby a good second.

Mr. F. P. Norbury, of Malvern, was the only exhibitor in the class open to Worcester, Hereford, Monmouth, Glamorgan, Carmarthen, and Pembroke, and he only showed apples; he was awarded the first prize for a very fair set.

The Welsh counties formed the next section, and here Mr. H. Forder, gardener to Colonel Cornwallis West, Ruthin, exhibited apples, and gained first prize for a moderate set; he was also the only exhibitor of pears, his best dishes being of Souv. du Congrès and Pitmaston Duchess.

Mr. J. E. Hathaway, gardener to J. Brennard, Esq., Baldersley Park, Thirsk, was the only exhibitor of apples from the Isle of Man and the six northern English counties, and he showed excellent dishes of Lord Derby, Bramley's Seedling, Mère de Ménage, Bismarck, Rival, and King of Tompkin's County; the same competitor brought the only set of pears, and these included a fine dish of Marechal de la Cour.

From Scotland, Mr. J. Duff, gardener to Colonel Gordon, Castle Douglas, brought fine brilliantly coloured examples of The Queen, Allington Pippin, Cox's Pomona, King of the Pippins, Peasgood's Nonsuch, and Warner's King apples, and was deservedly awarded the first prize.

Only one Irish grower turned up, and he only contributed apples, but these were handsome dishes of Loddington, Bismarck, Peasgood's Nonsuch, Cox's Orange Pippin, and Lord Derby, shown by Mr. T. E. Tomalin, gardener to the Earl of Bessborough, Piltown.

NURSERYMEN.

The principal class open only to nurserymen was for an exhibit of hardy fruits arranged on a space 20ft. by 6ft., and here there were five entries, these in themselves making a good fruit show. The competition was wonderfully keen, especially between the first three sets. After considerable deliberation the premier award of a gold medal was made in favour of Messrs. G. Bunyard and Co., Maidstone, who had a brightly-coloured and well-arranged group set up in three tiers, the front lines consisting of dishes of fruits and the central lines of elevated piled-up baskets of apples. Some few of the finest apples were Hambling's Seedling, Lane's Prince Albert, Warner's King, Rambour Franc d'Hiver, Gascoyne's Scarlet, Emperor Alexander, Wealthy, Royal Jubilee, Smart's Prince Arthur, Mère de Ménage, Brabant Bellefleur, Foster's Seedling, a handsome and highly productive variety, Transparent de Croncels, James Grieve, Winter Ribston, Lady Henniker, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, and Rival. Some dishes of plums, nuts, medlars, etc., completed the exhibit. The second prize fell to Messrs. H. Cannell and Sons, Swanley, who had a grand lot of fruit, and received the silver-gilt Hogg medal; the bloom on the cheeks of such apples as Allington Pippin, Smart's Prince Arthur, Blue Pearmain, Emperor Alexander, Gascoyne's Scarlet, Brabant Bellefleur, King of Tompkin's County, Mère de Ménage, Hoary Morning, Winter Peach, and Fraise d'Hoffingear added much to their attractiveness. The whole of the fruits were wonderfully clean and bright, both apples and pears. A silver-gilt Hogg medal also fell to the King's Acre Nursery Company, whose well-disposed collection contained fine baskets of Baxter's Pearmain, Admiration, Lawry's Cornish Giant, Schoolmaster, James Grieve, Blenheim Pippin, Allington Pippin, Rival, Sandringham, and Blue Pearmain. Messrs. J. Cheal and Sons, Crawley, and Messrs. W. Seabrook and Sons, Chelmsford, were also exhibitors in this class.

In the class for 20ft. run of fruit Messrs. Laxton Brothers, Bedford, secured the silver Hogg medal, and set up some splendid bas-

(Continued on page 766.)

SOME OF THE NEWER CULINARY APPLES.

Anyone accustomed to examine the catalogues of the leading firms of fruit tree specialists will not have failed to observe the very praiseworthy efforts that, in recent years, have been made to bring more into order the unduly extended lists of varieties of hardy fruits. This applies more particularly to apples. To assert that all, or even most, of the old varieties of these are inferior would be altogether too sweeping, but all the same there are great numbers still cultivated merely encumberers of the situation that should long ago have given place to others of well tried merit. That small, badly shaped, or inferior flavoured apples are now unremunerative to cultivate becomes more and more in evidence yearly, and as time goes on, and the splendid varieties that have been introduced in quite recent years become better known, a rigid selection and weeding out of old-time favourites must assuredly take place, and in many gardens and orchards the process would be highly beneficial. Subjoined are a few notes upon some of the newer culinary fruits, and their qualities for use, bearing and keeping qualities, as demonstrated in a Northern garden.

James Welsh.

This is an early apple of much promise, being of excellent quality for cooking, and the tree very healthy in growth. Like many of the early varieties the fruit buds are produced principally upon the points of the shoots, hence in pruning a thinning out of these where thickly placed is preferable to much reduction in the length of the branches, except of any that are inclined to gain an undue lead of others. The fruit is conical in shape, medium to large in size, the flesh white, firm in texture, and richly flavoured when cooked. The bearing qualities of the tree are all that could be desired; left to itself, too many fruits are produced for all to attain full size, hence the necessity for the thinning of these in good time. As a bush or pyramid, with the last-named attention being paid to the crop, the paradise stock may with advantage be employed, but for standards, where this course becomes wellnigh impracticable, the crab stock would prove more satisfactory.

Baillie Neilson.

A broad, rather flat fruit, in use from October onwards. Against a wall the fruits attain a beautiful yellow colour, which, however, is equally as prominent a feature this season in the open. The tree is very prolific, bearing freely when quite young. Though not a large fruit, and perhaps a trifle too broad compared with height to make a good market fruit to please all tastes, yet it is a grand variety for a private garden.

Early Victoria.

This very early variety is sure to replace several of the older sorts that for long have been held in esteem, as it possesses all the desired qualities as a cooking fruit, and has a very taking appearance. It succeeds well on either stock, and crops freely as a cordon or as bush or espalier trained.

Rivers' Early.

This is a noteworthy addition to the Codlin class, and one of the earliest to arrive at maturity; in fact, the fruits may be used whenever large enough to undergo the necessary ordeal of preparation in the kitchen. Size, colour, and firmness of flesh are well combined in this, and as cordons against walls, or the espalier railing, the strikingly beautiful, and for the season, large fruits, always secure admiration.

Norfolk Beauty.

Another season, and certainly a most favourable one for the apple crop, gives convincing proof that this is one of the most worthy additions to the list of midseason apples. Compared with Warner's King it is of better shape, quite as large individually, and equally as prolific, while it has the advantage of being a better and longer keeper, and does not show dark spots or markings under the skin, which so often occurs with the last-named after being stored for a time. I consider this a most desirable fruit, in use from September to Christmas.

Charles Ross.

Though classed as a dessert apple, this is more fit for culinary use in Scotland. For dessert size is against it, although it is of noble appearance, and worthy of cultivation as a show fruit. This year it is equally as large and well shaped as Peasgood's Nonsuch, and the latter is finer, more free from flaws, and of better colour from purely open-air trees than ever I saw it before, yet it is run very close indeed by the one under notice.

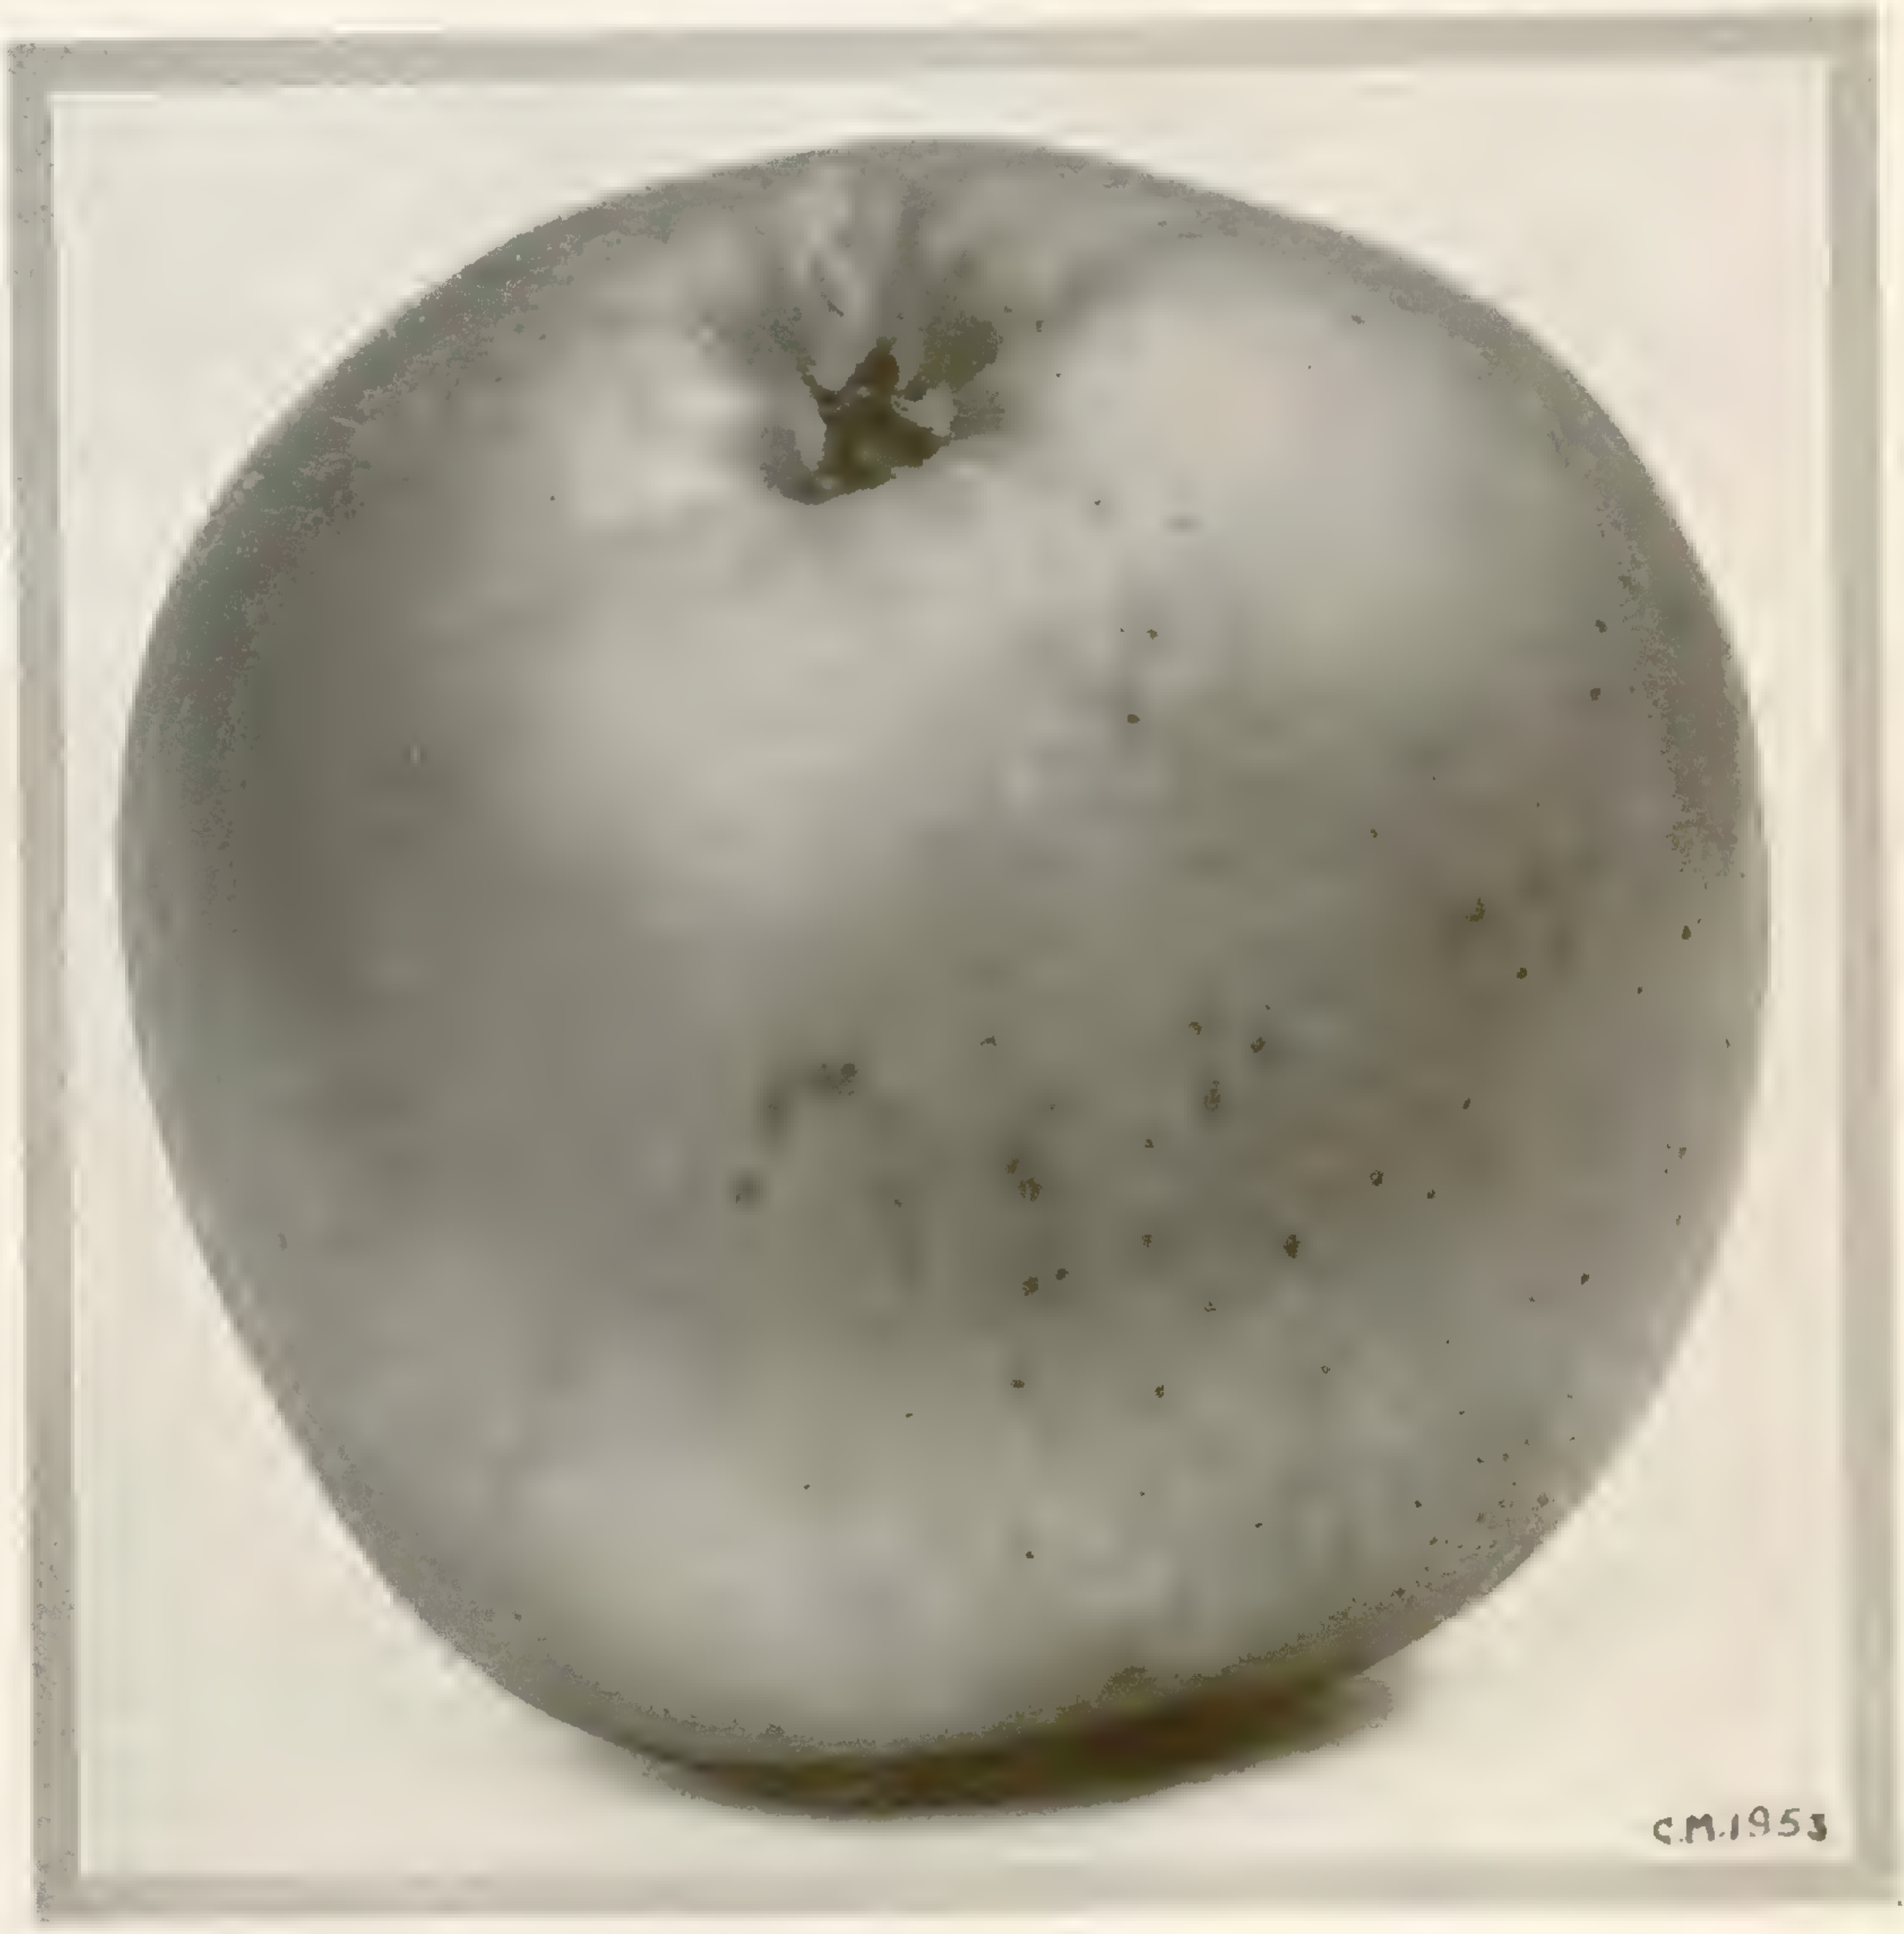
Newton Wonder.

For very late keeping this is sure to be valued when better known. The trees are of open, spreading habit of growth, and, trained in bush form, become in course of a few years very handsome objects, more particularly so when laden with shapely, high-coloured fruits. These should be left as long as possible upon the trees, and when gathering great care should be taken to avoid bruising the fruit, which, however, is not easily done, as for weight and solidity at the time this apple is almost unsurpassed. Kept in a cool room or store it may be depended upon to provide a supply either for culinary use or dessert when most other varieties are long since past. I have found this to be one of the very latest keeping apples, and it possesses all the good points looked for in a first-class fruit.

Edward the Seventh.

This is very large, and of bright yellow colour when fully matured, and one that seems to thrive under any form of training. So far it has not proved so fruitful in its earlier stages as some others planted at the same time in similar conditions, a defect, however, that may be overcome as time goes on.

JAMES DAY.



APPLE JAMES WELSH.

A culinary variety of great merit introduced by Messrs. Dickson and Co., of Edinburgh.

Eriostemons.—The Eriostemons are a very ornamental class of evergreen shrubs, all natives of Australia, and consequently they need in this country the protection of a greenhouse. They are exceedingly floriferous, so that most of them will bloom in a perfectly satisfactory manner as neat little bushes in pots five inches in diameter. Under more liberal treatment they will, however, attain a considerably larger size. There is a fairly long list of species and varieties, but through them all there runs a strong family likeness, they being for the most part of a dense twiggy growth, while the starry flowers are either white or pinkish. Eriostemons thrive in a mixture of loam, peat, and sand, and may be stood out of doors during the summer months.—W. T.

A FEW GOOD LATE DESSERT PEARS.

To have late pears in good condition and fit for the table throughout the winter and well on into March and April should be the aim of all who have to keep up a constant supply of dessert fruits. But this can on'y be done by allowing all late pears to hang on the trees as long as possible, and the grower will be called upon to exercise much patience, especially where tits are troublesome, the impulse being to get the crop stored before the greater part is lost. The penalty of early gathering, however, will be immature and flavourless fruit, doomed to shrivelling or decay.

Doyenne du Comice, rightly described as the best pear, may be considered late, as its season can be extended well on to Christmas by careful finishing and storing it. This variety, in constitution, fertility, and quality, is unsurpassed, making excellent trees in all forms, except perhaps as standards, few pears being rea!ly adaptable to this form. Le Lecteur, one of the newer varieties, will follow close upon Doyenne du Comice, and is really of first-class quality, resembling a small Pitmaston Duchess, except that the skin is of a greener tint. This variety is unfortunately not a heavy cropper, but coming into use when pears are getting scarce, room should, if possible, be found for a tree or two on an east or west wa'l. Glou Morceau is another pear worthy of a good position, as a well-finished fruit in January is delicious, and being a regular cropper and of excellent constitution this variety should be grown if a warm position can be given up to it; no other pear I know can quite take its place.

Josephine de Malines, one of the best known of all late pears, is another indispensable variety, its cropping capabilities and quality being good. It will do well grown as a bush or pyramid, often carrying heavy crops of rather small fruits. The trees need liberal feeding, and should be judiciously thinned to secure good quality. Duchesse de Bordeaux is a pear not so generally grown as it ought to be; all through February, and well into March, this variety, by being introduced into gentle heat in batches, according to demand, may be had in perfection. In such cases I have found it best to wrap late pears in paper and pack them as if for transit, placing the box in a temperature of about 55 degrees, where the fruits will gradually ripen.

Of great importance is the storing of the fruits when gathered; a dark place that is uniformly cool and moist is most suitable for late pears. I usually lay a coup'e of thicknesses of ordinary brown paper on the lattice-work stages, or shelves, and at the first spell of very sharp weather large sheets of the same kind of paper are laid evenly over the fruit, this being kept in position throughout the rest of the season.

James Whittle.

Cheveney Gardens.

Nerines.—Every autumn the nerines assert themselves as among the finest of all greenhouse bulbs that flower at this season. Of them all, the first place must, I think be assigned to a good form of Nerine Fothergilli, as the heads of flowers are large and bold, and the colour a dazzling scarlet.—W. T.

Plumbago Larpentæ.—Handicapped now by the terrible name of Ceratostigma plumbaginoides this charming blue-flowered member of the Leadwort family seems everywhere to have flowered this year with unwonted freedom, probably the past summer called up recollections of its Chinese home.—W. T.

CULTURE OF FIGS IN POTS.

The culture of figs in pots is not a new idea by any means. I remember it to have been most successfully practised quite thirty years back. Then it was Brown Turkey that was chiefly grown under this system. Since that time, and during the latter part of the occupation of the Chiswick Gardens by the Royal Horticultural Society, a very fine collection of figs was got together. This was the means of bringing into more prominent notice varieties which have proved most valuable acquisitions for the dessert. In addition, the trade have been the means of disseminating several excellent figs, notably so in the case of Negro Largo, which, I believe, was distributed by Messrs. James Veitch and Sons, of Chelsea, who also introduced Violet Sepor and those two fine early kinds, St. John and Pingo de Mel. These latter two are so much alike that only one of the two need be grown.

Undoubtedly the fine collection of figs at Chiswick, now transferred to the Wisley Gardens, has been the means of fostering the pot culture of this valuable fruit to a great extent. There is, however, still room for yet more extended culture under this system. It does not appear to be recognised by many growers how this may be accomplished. Yet it is comparatively easy to have a good supply over an extended season. All growers who cultivate the fig under glass upon the planted-out system know what a dense shade is imparted. The growth, when the trees have the run of a border, is often over-luxuriant, and the return in fruits not always so commensurate as it should be with the space occupied. Under pot culture, however, many kinds are far more prolific, notable so in the case of Negro Largo, Bourjassotte Gris, and St. John. The restriction of the roots when in pots tends to fertility, to more sturdy growth, and with leaves of lesser dimensions.

It will be readily conceded that the individual fruits are finer, on the whole, from planted-out examples, but these fruits, if larger, rarely, if ever, surpass pot-grown examples in point of flavour. Given a well-ripened fruit of either Negro Largo or Bourjasotte Gris, it is most difficult to beat for flavour, the saccharine juices being so fully developed. The pot system is a most distinct gain, for economy in space can thus be carried out to advantage. At the very most pot plants need not occupy the space at command for more than six months. Thus with two sets of plants the same house may be advantageously worked, or for six months it can be occupied by other crops. As a case in point we give up one house to extra early forcing, starting on November 1, or thereabouts, picking our first fruits on or about the middle of March. After this crop is gathered thé growth is completed, and the trees hardened, so that early in May they can be stood in a cooler house, and then the space thus vacated can be given up to another set of figs that have been retarded, or to a crop of melons if this be deemed expedient. The early lot of trees, after a few weeks, are stood outside, and thus become thoroughly well ripened.

It may be asked, "Do the trees stand this kind of treatment?" To this my reply is: We have plenty of examples that have been thus cultivated for ten years past, and the largest are only in ten-inch pots, with very few exceptions. It is a good plan to add a few young plants to the stock every year. The fig is easily propagated from eyes, or from the points of the shoots, or by means of cuttings of the young wood, if occasion arise. This process should commence, with the two former methods, early in January, and with the latter later in the spring. This season, for example, we started propagation the first week in January, and we picked our first fruits about a month ago from these young plants, one of which is illustrated in the present issue. These will continue to yield a good supply for another month or six weeks.

The following are a good half-dozen figs for pot culture: St. John, for first early use; Brown Turkey, to follow; then White Ischia, a delicious little fig; Grosse Violette de Bordeaux, a free cropper; Bourjassotte Gris and Negro Largo bringing up the rear, both being of the finest flavour. As a very late addition, D'Agen is an acquisition.

Jas. Hudson, V.M.H.

AUTUMN SALADS.

The great value of vegetables eaten in a raw state has been fully demonstrated during the past few months. The demand has been so large, and the supply, unfortunately, has been so inadequate, mainly owing to the intense heat and continued drought, that fabulous prices have been realised in many of our large centres, especially for lettuces. With the exception of tomatoes and cucumbers, both of which the season has suited remarkably well, the various subjects, such as lettuce, endive, etc., have been most difficult to obtain.

From a dietetic point of view the value of salads can hardly be overestimated, and as a relish they form an exceedingly tempting dish. Again, when these are most in demand it is quite possible for those with only ordinary means at command to grow a selection of suitable kinds in an ordinary season. Later supplies, of course, are different, and in the majority of large households salads are now required almost daily; these cannot be provided without the use of artificial heat and the necessary pits or frames.

It will be quite unnecessary for me here to detail the cultivation of cucumbers, beetroot, lettuce, tomatoes, etc., but I will deal with each subject briefly from the point of view of their use as salads. Before doing so however, I would just like to mention the good work the Royal Horticultural Society, as well as other leading societies, is doing in offering prizes for, and thus furthering the interests in, salads, not only among the exhibitors, but also the general public. A well-arranged and finely-grown collection is an object of considerable beauty, and sure to find plenty of admirers.

Lettuces are unquestionably the most important of all vegetables cultivated for salad purposes, and strenuous means should be adopted in every garden of any pretensions to provide them in some form on any and every day in the year, and with the aid of cold frames this can easily be accomplished, due regard having been paid to the varieties best suited for the various seasons of the year, of which there are now ample. The secret of success, however is making frequent small sowings throughout the year. During spring, summer, and autumn seeds should be sown at interva's of ten days, both of cabbage and cos varieties. Generally speaking, the best white cos varieties are held in the highest esteem, though in some cases cabbage varieties are preferred, but it is well to be provided with both. Lettuces should be pricked out quite early, immediately the second leaf is made, on fairly rich ground, making them firm, and guarding against slugs and birds. Abundance of water should be given during dry weather, and most varieties re-

SWEET PEAS.

THE EXHIBITOR'S HOUSE FOR TRUE STOCKS OF ENGLISH GROWN SWEET PEA SEED.

AWARDED 90 GOLD MEDALS.

Raiser of the following well known varieties:—Clara Curtis, Mrs. Hardcastle Sykes, Mrs. Henry Bell, Queen of Norway, Tom Bolton, Red Chief, Charles Foster, Marchioness of Tweeddale, Bolton's Pink, and many more of the leading varieties.

My New Set of NOVELTIES for 1912 are all good and distinct, and must be included in all up-to-date collections.

AFTERGLOW.

Awarded SILVER MEDAL, Ulverston, for Best Novelty, 1911.

A most distinct flower, and quite a new distinct break in Sweet Peas, a very vigorous grower, nearly always four true Spencer blooms on a stem. The base of the standard is a bright violet blue shading to a glowing rosy amethyst, wings electric blue. "Afterglow" is a variety I can strongly recommend for growing under glass for exhibition and without doubt the most distinct and telling novelty seen in 1911. "Afterglow" caused more attraction at the N.S.P.S. Exhibition than any other variety. No collection will be complete without it. **Per packet, 10 seeds, 1s.**

DOROTHY.

A giant rosy lilac self, which will be in great demand for exhibition. The colour is quite distinct from anything seen in Sweet Peas, and greatly admired wherever exhibited, this is sure to be a very popular variety on account of its pleasing and taking colour, besides being such a vigorous grower, the flowers are of extraordinary size, and well frilled, of the true Spencer type, with a large percentage of four-flowered sprays. **Per packet, 10 seeds, 1s.**

R. F. FELTON.

AWARD OF MERIT, R.H.S., 1911.

I have no hesitation in saying that it is absolutely the finest and the strongest growing Lavender yet introduced for exhibition or garden decoration. Habit of growth very similar to Elsie Herbert; always plenty of fours of the true Spencer type. **Per packet, 6 seeds, 1s.**

FLORRIE.

A very delightful, well-shaped flower of the true Spencer type. The colour is a rosy crimson-lake, the back of the standard being overlaid with a pleasing red chocolate, the inside of the standard and wings being shaded with soft lilac. The plant is a strong grower, producing its flowers on long stout stems, grand for exhibition, requiring a little shading. **Per packet, 10 seeds, 1s.**

PRINCE GEORGE.

AWARD OF MERIT, R.A.S., 1911.

This is an extremely handsome and distinct flower, and has caused great excitement amongst lovers and admirers of the Sweet Pea. The standard is a warm lilac-rose, base of standard solferino red, wings violet-rose; it is a strong grower, and always abundance of four of bloom-sprays; a gem for exhibitors; very scarce. **Per packet, 6 seeds, 1s.**

The above are all Fixed Novelties.

Please send for Autumn List of all the Latest Varieties, post free.

PLANTING SEASON.

By Appointment.

WM. PAUL & SON,
WALTHAM CROSS, Ltd.

Nurseries twelve miles from London; south entrance four minutes' walk from Waltham Cross Station (Great Eastern Railway); west entrance five minutes' walk from Tramway Terminus.

SPECIALITIES:

ROSES in all forms, from open ground and in pots. Roses in pots, both dwarfs and climbers, extra fine this season.
FRUIT TREES, for the Orchard Garden, and Forcing House.
HARDY TREES, for Street, Park, and General Planting.
SHRUBS, Evergreen and Deciduous, for General Planting.
HARDY CLIMBING PLANTS for all purposes.
RHODODENDRONS, CAMELLIAS, AND AZALEAS. Rhododendrons from loam, extra fine this season.
HERBACEOUS PLANTS in great variety.
BULBS AND SEEDS and all Garden Sundries.

PRICE LISTS ON APPLICATION.
Inspection Invited.

Upwards of 1,000 Gold Medals, First Prizes, and other Awards at Leading Exhibitions during the past 50 years.

Sole Postal Address—

quire a distance of a foot apart to do well. A capital place for growing summer and autumn lettuces is on the ridges between celery and leeks, but a small plantation should always be made during July and August on a north aspect.

Endive requires much the same kind of treatment as lettuce, except that the first sowing should not be made before July, and the last about the first week in September. Earlier sowings will invariably prematurely run to flower. Both Batavian and curled varieties should be cultivated, and the late sowings be lifted and planted in cold frames for late autumn and winter use.

Chicory is one of the most wholesome, and probably the most serviceable and useful of plants cultivated for autumn and winter salads. Seeds should be sown at intervals during the spring and summer on deeply tilled soil, and the plants be thinned to ten inches apart; when full grown they are lifted, and forced as required in a dark position in the mushroom house or cellar.

PEAR DUCHESSE DE BORDEAUX.

An excellent late dessert pear, the tree bears freely, and the medium sized fruits are richly flavoured.

The cultivation of celery is too well known to need discussion here. Suffice it to say the very best varieties only should be grown. Abundance of water must be supplied, both to the roots and overhead, and blanching should be done for all early batches by the use of strips of brown paper, added at intervals.

Medium-sized beetroots should be the aim of every cultivator, and I am glad to know that this is the aim much more than was the case a few years ago. Beet should not be sown too early, and the crop should be lifted immediately it is fit for table, and stored in a cool place, when it will be found to keep perfectly until the following spring. There are many excellent varieties both of the black and red types, and the Egyptian or turnip-rooted form is invaluable for very early supplies.

The contrast between well-grown radishes selected and used at the proper time and those generally seen on the market is most apparent. In quite the majority of cases radishes are allowed to become too old before they are eaten. Good light ground should be selected, and frequent sowings made. From four to six weeks, according to the season, will be found quite long enough for radishes to come into use. The French Breakfast is still the best for general purposes.

Mustard and cress are possibly the simplest of all things to cultivate; nevertheless there is a right and a wrong way to deal with them, and to maintain an unremitting supply is not always so easy as it appears. During summer and autumn they should be grown in a shady position, and kept constantly damped. The seeds should be pressed in firmly, but never covered.

Cucumbers, during the summer and autumn, can be successfully and easily cultivated in portable frames on a mild hotbed. Make choice of a well-known variety of a prolific character, and of medium length. The growths should be regulated, and kept fairly thinned out, the roots well supplied with water to prevent bitterness in the fruits, and no fruits should be left on the plant after once fit for use.

To ensure a regular supply of tomatoes it will be necessary to cultivate them under glass, but in a summer like the past, by putting out good strong plants at the end of May little difficulty will be found in providing large crops of excellent quality either in an open sunny position or against a south wall. The growths should be kept well thinned, and the roots supplied both with water and liquid manure after the fruits have set; the fruits should be removed immediately they show signs of colouring, and placed in a warm position. Sunrise is the best variety I am acquainted with.

Aldenham Gardens. E. **Beckett.**

SUCCESSIONAL PEACHES FOR OPEN WALLS.

Although peaches are successfully grown in many gardens upon open walls, this method of culture might be profitably extended, even in situations not altogether favourable, provided the necessary precautions are taken in order to counteract the existing evils.

With reference to this it may be said that at The Hendre some of the conditions are far from being ideal for outdoor peach culture, and yet, by taking extra pains in some of the details of management, satisfactory crops are invariably secured. Last year, nevertheless, though we had full crops of fruit, the flavour, owing to the state of the weather, was poor in quality, and we had rather light crops this year.

The chief of the unfavourable conditions that we have to surmount are a low situation, where spring frosts prevail, and a heavy, tenacious, cold soil. In dealing with these, in order to secure healthy root action and the formation of fruitful wood, it is essential to pay careful attention to the drainage of the borders, and otherwise improve them by adding suitablomaterials, and also to lift the trees periodically and prune the roots. It is also necessary to efficiently protect the blossoms and young fruits from frosts, and under all conditions, whether favourable cr unfavourable to peach culture, it is especially important to, as far as possible, keep the trees free from attacks of injurious insects and such fungi as promote leaf curl, mildew, etc. Further, the great benefits to be derived from thinning and training the young shoots without letting them become crowded must on no account be lost sight of. However, the fear that I am digressing somewhat from my subject for-tree is compact, and bears good crops in the majority of seasons. Kerry Pippin succeeds well with me; the tree fruits well, and when the crop is gathered at intervals the season is greatly prolonged. I consider the flavour of this apple excellent, and rank it among the very best of our early dessert sorts. Worcester Pearmain grows freely, and the fruit puts on good colour; the tree is neat, and crops with great freedom. Lady Sudeley and James Grieve are excellent apples, the latter being of special value as a dessert fruit, while the flavour leaves little to be desired. King of the Pippins and Cox's Orange Pippin crop heavily on the bush; Ribston Pippin is not quite so free, but one of the best, and should find room in every collection. Egremont Russet is a neat grower, and fruits well in most seasons. Scarlet Nonpareil, Duke of Devonshire, and Lord Hindlip are capital varieties for supplying late fruits, but the crop should be left on the trees till very late, otherwise it will not keep fresh and plump.

Of cooking apples some capital varieties will be found in the following selection: Grenadier, Ecklinville Seedling, Peasgood's Nonsuch, Golden Noble, Bismarck, Warner's King, Lane's Prince Albert, Chelmsford Wonder, Bramley's Seedling, Newton Wonder, Byford Wonder, and Sandringham.

Although there are numerous other excellent varieties, those I have mentioned will succeed, and give every satisfaction in almost any form—whether bush, pyramid, or standard. When planting young trees the soil in which they are to be grown should be well broken up, and if not suitable some good fertile loam should be obtained and mixed in with the staple. Manure, in cases of poor soil, should be added; but if the loam is good, very little manure will be needed until after the trees have made good headway, when some artificial feeding must be given to keep the growth in a healthy fruiting state. Another point in connection with young trees is to allow ample room for each tree to grow. I consider 12ft. to 14ft. apart for most varieties is about the right distance to plant, so that both light and air may reach the interior of the bushes, and better results will certainly follow.

H. Markham.

ONE OF THE SPAN-ROOF FIG HOUSES AT GUNNERSBURY HOUSE.
The trees on the left-hand side of the pathway are all about eight months old, and those on the right have been in bearing some years.

CULINARY PLUMS.

None of our hardy fruits, except, may be, the apple, are of more value than plums, for they are capable of being used in a variety of ways. But in order that their usefulness may extend over as long a period as possible in a fresh state, it will be necessary to grow several varieties ripening successively, as there are but very few that will keep for any length of time when fully ripe. The list of varieties to choose from is rather an extensive one, and those who have only a limited space at their disposal would do well to confine themselves to a few of the most prolific.

Some years ago I planted a collection of all the varieties I could procure with a view of testing their merits; some of them were a complete failure, others of but little value from a commercial point of view, while others seldom failed to give us fruit, more or less, according to the season.

Not only is it advisable to plant in variety, but it is well to plant in various positions if possible, such, for example, as planting some of the early kinds on a south wall and some of the late ones on a northern aspect in the more southern counties. As is generally known, plums thrive better in rather a dry soil than a deep heavy loam or stiff clay, for when grown in the latter they are apt to make too much coarse growth, and are therefore on that account less productive. Plums, as a rule, are hardy, though, flowering at an early period of the year, they are very very apt to suffer from late spring frosts when in bloom, especially when grown in low-lying places; on higher ground and in lighter soils they do not seem to suffer quite so much in this way, especially if shelter be afforded from the north and east.

When planting an orchard of plum trees due consideration should be given to the varieties, as some grow much stronger than others; therefore, the more robust kinds should be kept by themselves, and, if possible, the hardiest sorts, such as damsons, should be planted round the outsides to form shelter. Some recommend planting a belt of trees for this purpose, but unless these are a sufficient distance away they are apt to overshadow the fruit trees, preventing the wood from maturing properly, and therefore rendering them less fruitful. The distance the trees should be planted apart must, in a measure, be determined by whether it is intended to cultivate the land between them or not, but undoubtedly the most profitable mode is to plant about eighteen feet apart and grow another crop between the trees.

In making a selection for private use it is well to have a few trees of early, mid-season, and late kinds, rather than a lot of one sort, as they will then ripen in succession. Of those ripening in July there are not many, but we should certainly plant a tree of Reine Claud Violette, or Purple Gage, as it is sometimes called. If one of these occupies a position on a south wall the fruits will open early, but as the tree is perfectly hardy in most places it will succeed well as a standard, bush, or cordon. Early Rivers is also a good variety, is most prolific, and may be grown as a bush or standard. Then we have the Early Green Gage, and to succeed these there is a variety known by the name of Stint, which is very prolific. The fruit is small, of a reddish-purple colour, and very juicy. The tree is rather a slender grower, and therefore needs pruning rather hard when grown as a bush or standard, otherwise the branches have not sufficient strength to support themselves in an upright position.

Of plums ripening in August we have a greater variety to choose from, but it is not well to plant more than sufficient trees of each to keep up a supply, unless it is intended to market the fruit, and then bushes or standards are preferable to wall trees, as these latter should be of choicer kinds. Belle de Louvain is a large handsome variety that should find a place in all gardens. As a bush or standard it is most prolific, producing fruit when most other kinds fail. Czar is a large oval variety having a reddish-purple skin; it is a free bearer and of good flavour, and succeeds well either as a standard, bush, or cordon.

A POT SPECIMEN OF THE WHITE ISCHIA FIG.

As grown by Mr. J. Hudson, V.M.H. The tree when photographed was eight months old, four feet in diameter, and carrying a crop, some of the fruits being ripe.

Prince Englebert is a large dark purple variety, oval in shape, and of good flavour, in fact, it is one of the finest kinds that ripen at this period. Pershore is a variety largely grown in Worcestershire, especially round Pershore, where it originated. The fruit is rather above medium size, having a tough skin, which makes it so valuable as a market fruit.

There are a number of plums that ripen during September, including the various damsons, though in some places these will hang on the trees until well into October. For cooking, bottling, and preserving, no kind is more useful than the damson, which is hardy, and will grow almost anywhere, and on that account shou'd be planted in the hedge-rows for shelter. The Bush plum, or, as it is sometimes called, the Wellington, is a very free variety for culinary purposes, and, as the skin is tough, it is not so liable to be eaten by wasps as some others. Monarch is worthy of a place in all gardens, and whether grown as a bush, standard, cordon, or against a wall, it is alike useful. The fruit is large, of a roundish, oval shape, and the skin is covered with a thick bloom, which makes it attractive; it hangs well on the trees, not being so liable to rot as some kinds. Victoria is undoubtedly one of the most popular varieties in cultivation, and one that usually commands a good price in the market. Either as a wall tree, bush, standard, or cordon, it is alike valuable, for it rarely fails to produce a crop of fruit, even when others fail. Washington is a fine variety, but the fruit is apt to crack in wet seasons when grown on standards or bushes, but as a variety for a west wall it is excellent. When young the tree is rather a robust grower, therefore should not be planted in too rich soil. White Magnum Bonum is an old variety that still deserves a place, and when grown as a bush or standard will usually give a crop.

Of varieties that are in use during October and November there are not many, still there are some that do well, especially in the more southern counties. Archduke is one of these; the tree is hardy and most prolific, either as a bush, cordon, or standard; fruits large, hanging well on the trees. Grand Duke when grown against a west wall will produce fruit of extraordinary size. It is like the Magnum Bonum in shape, but the colour is a deep purple. It does well either as a pyramid or standard. President is a variety of more recent introduction. I planted some trees the first year that it was sent out, and was much pleased with it; the fruits are large, carrying a deep blue bloom, and hang well on the trees.

There are a few varieties that are not generally grown that hang well and retain their freshness after the leaves have fallen. Wyedale is one of these; the fruit somewhat resembles that of the Shropshire damson, but the skin is tough, the fruit retaining its briskness sometimes until the middle of November. Late Orange is also another good kind that hangs well, especially when grown against a wall. Late Black Orleans, when grown as a bush in a sheltered place, will also give fruits very late in the season.

In some parts of the country I have seen two varieties of the Bullace growing wild; they ripen their fruits late in October or early in November, when they are much appreciated for tarts. There has of late years been an improvement among these due to crossing them with late varieties of plums. One known as The Langley is a most profuse bearer, and it is a cross between the Farleigh damson and Late Black Orleans plum. This is a most useful kind, as it keeps well until late in the year, and those who require such fruits would do well to plant a few trees in the hedge-rows or put them in odd places where other varieties will not thrive, as it is a most ornamental plant when the fruits are ripe, these hanging in clusters along the slender stems, even after the leaves have fallen. H. C. Prinsep.

CRINUM POWELLI ALBA.

I recently saw a very fine batch of crinums growing and flowering freely in a garden near the sea on the coast of Hampshire. The soil is a deep loam, peaty and gravelly in places. But it does not lie much above the level of high tides, and even in a dry season there must be a great amount of moisture in the subsoil. Although all the crinums were flowering well, the one named above was the most attractive at the time of my visit, as it was so pure in colour.

The bulbs and stems were exceptionally strong, the leaves broad, long, deep green in colour, and numerous on every plant. They thrive best in a rich loam, medium as regards texture, and as they produce many offsets it is a very easy matter to increase the stock. Readers who may have some gently sloping and sheltered ground near a pond or stream, may deeply dig up and enrich such soil, and then make a colony of crinums there. The plants do very well in such moist places, and become strong in an incredibly short time. The position should be such a one as to enable the cultivator to supply the plants with abundance of water during the growing season. The flowering season is throughout July and August.

Geo. Garner.

APPLE CRIMSON BRAMLEY'S SEEDLING.

Messrs. H. Merryweather and Sons, of Southwell, Notts, did a great public service in introducing that splendid apple known as Bramley's Seedling. This free growing and abundant cropping variety is a great favourite, and its merits as a culinary apple have been often discussed in these pages, always to its advantage. Now, however, we are to have a new form of the old favourite, and Crimson Bramley's Seedling is an exact counterpart of the type in all except colour. It is a sport from Bramley's Seedling, and resembles the original in size, shape, and habit of growth, the only real difference being that the fruits are coloured almost all over with bright crimson, and thus a very attractive appearance is added to great usefulness. When the crop is approaching maturity a tree of Crimson Bramley's Seedling presents a very handsome picture. The newcomer seems quite likely to make as good a name for itself as its less showy progenitor has.

THE HARVEST OF THE ORCHARD.

By "orchard" I do not mean any of the comparatively modern enclosures under cultivation, in which standard trees are interspersed with pyramids and have small fruits between; where only a few selected varieties of commercial value are grown, and the whole thing is run on business lines; but to an orchard such as it is known in the West Country, where apples and pears were grown for centuries before the modern plantation was devised, and the like of which may be seen attached to scores of farmsteads in the western counties. From the point of view of the modern up-to-date commercial fruit grower who makes this his business, and has nothing to do with anything else, the farm orchard of the West Country is something to ridicule, a place where apples and pears are not cultivated, but just grow according to their own sweet will, and demonstrate what ought not to be rather than what ought to be done in the way of cultivation. As a matter of fact, the typical West Country orchard seems to have little in common with modern methods of commercial fruit culture, and it is, just what it always was, a kind of a side branch of farming, on which, in the majority of cases, very little money is spent in the way of cultivation.

Yet, in the West Country, the orchard, subjected to ridicule as it is, the happy hunting ground of writers on fruit culture, who have rarely a good word to say for it, is a valuable asset to both landlord and tenant in the counties where orcharding is part of the agricultural industry. As evidence in support of this statement, one has only to attend a property sale at which land is disposed of under the hammer. One lot is knocked down, perhaps, at forty pounds an acre, good pasture ground may be, but when the next, which is precisely the same kind of land only that it is described as orcharding, and is furnished with trees, is put up, the bidding becomes more brisk, and probably will run up to a hundred pounds an acre before the hammer falls. This is not fiction, mind you, but fact, and only recently a gentleman of my acquaintance bought a piece of grazing land at forty pounds an acre, and another piece, only divided by a hedge, at a hundred, the difference being that the latter was furnished with fruit trees and described as an orchard.

As with selling so with letting, the farm with a certain number of acres of good orcharding in the West Country is let at a much higher rental than another holding which might be equally good except for the orchards, and when selling out, on an average, double the amount is allowed for land furnished with established trees as for that which is not classed as orcharding. Yet to the eye of the fruit expert these orchards do not look much; they appear, in many cases, to be neglected, and display a want of attention and a marked absence of anything in the way of cultivation. In fact, one wonders what they would be worth if they were what we consider orchards ought to be, but that is part of another story.

Just so, but I am writing of the harvest of the typical West Country farm orchard, and it comes when the glow of autumn steals over the country, when the blackberries ripen on the thick surrounding hedges and present a means of bringing some acceptable grist to the mill of the cottage folk, who look to blackberry picking as a means by which the family income can be supplemented to some extent.

Let us, then, step into one of the scores of West Country orchards at harvest time, which is earlier this year than usual, as the result of the tropical summer. We enter the orchard by way of a gate through the stack yard, for the farmer, who in bygone times was responsible for the planting of the trees in the first place, exercised sensible judgment in establishing his orchard not far from the homestead and the cider mill. Probably he did this because the orchard is, strictly speaking, neither pasture nor meadow; though it does duty as both; but it is a handy enclosure, close to home, convenient for ewes and lambs in the early spring, where calves can be run and kept under notice, and pigs can forage about in search of food that never would be found by anything but a member of the swine family.

In autumn days, however, when the harvest of the orchard is being gathered, neither sheep, pigs, calves, or other stock are allowed access for reasons that are obvious, and the grass that grows luxuriantly underneath the trees is left to flourish until the last of the apples are gathered.

APPLE CRIMSON BRAMLEY'S SEEDLING.

A valuable culinary variety, possessing the merits of Bramley's Seedling, but differing from it in being bright crimson. Introduced by Messrs. H. Merryweather and Sons, Lim.

The first thing that strikes you on entering the orchard is the method, or rather lack of method, in arrangement. It would appear as if the trees had just been dropped in places where there was room for them, and in places, too, where there was not room, for many of the orchards are hopelessly overcrowded, and, though at the original planting there might have been some attempt at orderly arrangement, this has long since been broken up by sticking in trees here and there from time to time where there appeared to be a little vacant space.

As with the arrangement so with the trees. There are some stalwart specimens, with big, spreading limbs, almost like forest trees; others which look as if they had been dying for half a century and yet would not give up the struggle, and others again with trunks lying flat on the ground, evidence that at some time or other they had been blown over. Nobody had taken the trouble to pull these back into an upright position, so they have decided to grow just where they fell, and their want of perpendicular seems to have little effect on their cropping powers. There are trees of all ages, too, in the typical orchard, including old patriarchs with thick stems and massive limbs, but more or less decrepit; trees in the vigour of their prime; others that have been remade by grafting; and young trees that have been planted in recent years to fill up gaps. A heterogeneous collection they appear to be, old, middle-aged, and young all mixed up together with very little order or system in arrangement, and not much evidence of cultivation; but, in spite of all this, do not forget that their presence adds a matter of fifty pounds an acre to the selling value of the land.

As for the varieties, well, I should like to see a collection of apples from a West Country orchard placed before the Fruit Committee of the R.H.S. to be named! The experts round the table would have to give it up, and yet the farmer knows his apples just as he knows his cattle or his horses. There are several types of fruit in the orchard, including, may be, a few old Blenheims and other well-known varieties, the fruit from which is picked and sold by itself or kept for household purposes; and amongst the younger trees you see a fair representation of Bramley's Seedling, Warner's King, and other well-known apples of commercial fame, for it must be said of the farmer that in his planting during recent years he has selected varieties which experience has taught him fetch the best prices in the market

The modern varieties seem but few, however, and who, then, are the customers for the fruit of the orchard at harvest time? The known apples of recognised commercial value find their way to market, and doubtless they would fetch more if they were packed in a less rough and ready manner, and more discrimination was made between good, bad, and indifferent specimens; and then the jam maker has his toll of the orchard, offering, may be, his four pounds a ton for the fruit, and it is surprising in these days how many apples are used for preserving, though it is a rare thing to see apple jam offered for sale!

Finally, you come to the cider fruit, and underneath the trees you see big heaps of apples, some yellow, others green, and others again red and tempting, but appearances are deceiving, and the names are unfamiliar, for the farmer, as he walks from tree to tree will tell you that this is a Killboy, that an Ansell, the next a Slack-my-girdle, the next a Kingston Black, followed by another and another, but the names are all foreign to you, unless you are a native, because they are all varieties of local origin, raised mostly in the dead and gone past from pips thrown out from the cider mill. You may, perhaps, question the value of these cider apples, but the trees are big, the apples, though small, simply hang in wreaths, the crop of a full-developed specimen is enormous in a season when the particular variety "is in," and this year, with cider fruits ranging from three to four pounds a ton, the return is very considerable.

This season the harvest of the orchard is of more than usual importance, for, though at the moment of writing, the trade in table fruit is by no means brisk from the point of view of the seller, cider casks are empty, and the West Country farmer is realising that, after all, it is not only table fruits that pay. And those heaps of red-cheeked apples in the orchard at harvest time, what becomes of them? Some go into the mill to be ground up for replenishing the cider hogsheads for domestic purposes, and others are collected in sacks, and sold to the people who make cider for commercial purposes. This year, owing to the reasons explained, there is a keen demand for them, the possibilities of cider fruits are realised, and though from £3 to £4 a ton does not seem much, think of what a big tree will produce, and remember that a good orchard puts a matter of fifty pounds an acre on to the selling value of land in the West Country. H.

CARMICHAELIA AUSTRALIS.

The order Leguminosæ contains a number of out-of-the-way shrubs which are hardy in the warmer parts of the British Isles, and are well worth growing by people who form collections of rare and curious shrubs. The plant under notice is included amongst such, and though it has long been grown in botanical gardens, it is, comparatively speaking, unknown in gardens generally. A native of New Zealand, it grows into a bush two to three feet high, with slender, rush-like branches, which are but sparingly clothed with leaves. From buds on these branches, however, numerous pea-shaped lilac-coloured flowers appear in July, which are in such numbers as to almost hide the branches. It is rather difficult to manage, particularly if it has to be transplanted after it has attained a moderate size, therefore an effort must be made to plant it in a permanent position when quite small. Sandy loam, in which a little peat has been mixed, appears to suit it better than an all-loam rooting medium, whilst heavy cold soil is undesirable. Seedlings may be raised from home-saved seed, and it is also possible to raise a stock from cuttings, these to be inserted in sandy soil in a close case in July. D

Roses may be grown to perfection by following the instructions given in ROSES AND THEIR CULTIVATION, **by T. W. Sanders. A selection is given, with description** of all the best varieties, and full details for culture outdoor and under glass. Price 2s. 6d. net, by **post in box 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.**

CHERRIES.

Varieties of cherries have of late years become numerous, so there is a good selection to choose from for the various purposes to which the fruits are adapted. At one time the only two late varieties were Morello and Late Duke, which were only used for cooking, being too acid for dessert. The cherry was formerly considered purely a summer fruit, but since the days of cheap horticultural buildings, a more extended knowledge of cultivation, and a greater number of varieties, their season of usefulness in a fresh state has been considerably extended, and they may now be had from April to October in perfection. None of our hardy fruits are better adapted for culture under glass, whether early or late kinds, their size and flavour being very much enhanced by this method, provided a suitable selection is made for that purpose.

Some of the varieties do well in pots, while others succeed better as cordons or trained trees against the walls of houses, but whichever mode is adopted care must be taken not to overcrowd the growths. When grown in pots, either as cordons, bush, or gridiron trained, they usually give satisfaction, and where a constant supply of the luscious fruits is desired throughout the season, it is a good plan to have a house set apart for them. Grown in this manner, the fruits are not only larger and of better flavour, but, owing to immunity from early spring frosts when the trees are in bloom, and from the attacks of birds, a full crop may generally be gathered from a limited space. It is, however, not all varieties that are suitable for pot culture, several not fruiting well until the trees obtain some age.

Those who are desirous of having a fine, large, well-flavoured black variety would do well to secure a tree or two of Black Tartarian. This is rather tender, but when grown under glass, either trained against a wall, or in a pot, it will produce fruit most abundantly. The foliage being very large, the shoots should not be overcrowded. Elton is another fine old variety that succeeds well under glass. Frogmore Early Bigarreau, when thoroughly ripened, is an exceedingly showy variety of a pale yellow colour, mottled with red. Bigarreau is also a fine variety that succeeds well under glass, and so do Bigarreau Napoleon, Geant de Hedelfinger, Bigarreau de Schreken, Early Rivers, and Governor Wood. There are others, but these are among the best.

Not only is it desirable to grow some of the finest varieties under glass, but a place should be reserved for them on the various walls in the open. Some of the earliest kinds grown on a south wall will succeed those under glass, while the mid-season and late kinds, if planted against a north wall, will prolong the season considerably. Trees for a south wall should include Early Rivers, Bigarreau de Schreken, Bigarreau, Noir de Schmidt, Empress Eugenie, Guigne d'Annonay, Reine Hortense, and a new variety named The Noble. To prolong the season as much as possible, some of the later kinds should be planted against a north wall. We have had Florence in grand condition when trained on this aspect, as late as September, while Guigne de Winkler will hang well until October; the same may be said of Late Duke and Late Black Bigarreau, and in some seasons St. Margaret's is also very fine grown thus, and so are Aston and Belle Magnifique.

In many places cherries do well as standards, but birds have become so numerous that it is difficult to preserve the fruit from them until it is thoroughly ripe, but where the country is open, standards do well, especially of such varieties as May Duke, Black Eagle, Aston, Black Heart, White Heart, Morello, and Kentish.

Some nurserymen make a special feature of growing fruit trees in pots, and those who are contemplating an orchard house would not do wrong to purchase the trees already established, as a season would thus be gained. It is, however, not essential for them to do so, as those lifted from the open ground, if not too large for pots, may be grown for a season after potting in the open to get established. Cherries, as most people know, bloom early in the season, before the weather is very warm; the bloom buds develop gradually, therefore when grown under glass, it would be courting failure to try and push them on too rapidly at this stage. It does not take the early varieties long to ripen their fruits after stoning; therefore it is not difficult to calculate the time trees started at a certain date should have fruit ready to gather. It is by means of a regular temperature that the fruit is brought to the highest state of perfection, and this, together with constant attention to cultural requirements, will give the finest results. On no account should the trees be allowed to suffer for want of water at the roots. The foliage must also be kept clean by fumigating and syringing until the fruits begin to ripen, when an excess of moisture in the atmosphere would cause splitting. Some of the varieties of cherries produce very large foliage, and with such kinds it will be necessary to keep the shoots a sufficient distance apart to allow air and light to circulate freely among them. Some varieties, Early Rivers, for instance, that make long-jointed growths, must be pruned rather hard to cause them to make more fruit buds; others, like the Black Eagle, should be allowed to extend their shoots somewhat, and when carrying a full crop of fruit should be encouraged to make a proportionately extended growth to keep the trees in a flourishing condition. After the fruits are gathered the foliage should be kept clean to induce the formation of fruit buds more freely.

It is a common mistake to have trees on walls trained with a centre shoot. Where the cultivator cannot train a tree properly he should grow nothing but single cordons. There is quite as much pleasure in seeing a well-trained tree as in producing the finest fruit, yet comparatively few gardeners nowadays appear to know much about training. This is one of the lost arts in gardening. Not one in fifty of the present-day gardeners could train a peach, cherry, or plum tree as it should be trained, for the simple reason that they have never been taught how to commence the operation. They have not the faintest idea where a shoot should be cut back to, or on which side the leading bud should be to produce an evenly balanced specimen. True, a tree may neither produce finer fruit or a heavier crop because the shoots are nailed symmetrically to the wall, but the work not only gives great pleasure to the owner and the person in charge, but allows of a more even circulation of air amongst the shoots and branches, and consequently a more regular crop. Training is an art which does mend Nature, changes it rather, and those who are adepts at it would do well to teach the rising generation of gardeners how such work was done in their day and in the times before them. It is not enough to say that insect pests must be got rid of; means should be taken to prevent them making their appearance, and when the trees are dormant is the best season for doing this. We pay special attention to the cleansing of stove plants, look well after insects on the chrysanthemums and like subjects, never permit the mildew on carnations to make headway, yet we are at a loss to know how it is that there are small holes in the foliage of our fruit trees, or that they are attacked with silver leaf, gumming, or canker. To grow fruit of the finest quality the trees must be free of all these troubles; therefore the cultivator must make himself acquainted with their origin. What is silver-leaf? Well, it is a fungus that attacks fruit trees, plums, and cherries in particular. If the cultivator will take the trouble to examine the roots of such trees he will find them in a most unhealthy condition; they will not have those fine flourishing fibres that are to be found on healthy trees, but will be covered with small nodules a few inches apart. When trees are in this condition, it is a sign there is something wrong with the drainage, that the soil has become sour and requires attention. Small holes are often caused in the leaves by the shot-hole fungus, and canker often comes through poverty in the soil; in each and every case it is essential that the cultivator be in a position to cope with the evil ere it is too late.

P. H. C.

GUNNERAS.

The plant of Gunnera manicata, so finely figured in the Gardeners' Magazine of September 2, was placed in its present position in March, 1909. It was a side crown from one of the large specimens. There are numerous larger examples than the one illustrated, but it has leaves 8ft. across and a height of 10ft. The largest leaf we have grown was 10ft. across, and a dozen men could easily have found shelter from rain under it.

Gunneras do not in many cases receive as much attention as they require. They need a moist position, and, if possible, one near a stream or lake, but in the event of such positions not being available, a good-sized hole should be dug at the back of the plant and clayed up, so that it will hold water, and this should be kept full, so that a gentle and gradual supply of moisture will be provided for the roots. Good dressings of cow manure should be given, with an occasional dose of nitrate of soda during the spring. We have many large groups which are most imposing all the summer.

Gunnera scabra is smaller than G. manicata, and the leaf stalks are bright red. It likes plenty of moisture and looks extremely well in boggy borders and in damp valleys. G. magellanica is a small creeping species, which thrives in bog soil or peat; it is quite hardy and is a great contrast in size to the former, as it only measures two inches across the leaves. It spreads rapidly by prostrate rhizomes which cover the ground and form a fine green carpet. This species is found in the Falkland Islands and is sometimes called G. Falklandica.

Another and still smaller species is Gunnera monoica, found, I believe, in New Zealand. This requires a shady, moist position. Still a very scarce plant in this country, it is a very pretty one, and the foliage is less than one inch across. It must at all times be kept cool, but in sharp weather a little covering should be placed over its foliage, such as some dry bracken or heather; or a small thatched hurdle may be used, as, unlike the large-leaved species, this one is evergreen. We have plants growing with sarracenias, a position they seem to like well.

It may be noted that all the gunneras require a slight protection in the spring, as they are apt to be cut by sharp frosts. Our plan of protection is simple. When the foliage of the large types is cut down in early winter some dry bracken is placed over the crowns and one or more of the large leaves put over the bracken. This protection is not moved until March, when it is eased and gradually reduced until the weather permits entire removal.

W. A. Cook.

LIME.

Among the mineral constituents of plant food none is more valuable or more widely distributed than lime. It exists in chalk, limestone rocks, marble, marl, calcareous spar, bones, etc., either as carbonate of calcium or phosphate of calcium. In its natural condition it is slow in action, but when converted into quicklime, and either ground or slacked, it is much more readily available to growing crops. In this condition, too, its neutralising properties are most active, and when a sour soil is being dealt with or a crop languishing for want of this particular food is under consideration, no better form of lime could be employed.

As a more slowly acting form of lime is desirable for some purposes, chalk, air-slacked lime, finely-ground bones, and basic slag will best meet these requirements. In the formation of vine borders old plaster or mortar is preferable to any of the foregoing, as it is not only slow in action, but also contains a percentage of soluble potash and silicates, both of which are valuable to the vine. For general purposes chalk, quicklime, either air or water slacked, will be found admirable where the aim is simply to provide a supply of this ingredient of a fertile soil. Ground quicklime is the most active of all the forms, and on this account it should not be employed until there is growth in the crop on the land to which it is applied. In its caustic condition it quickly breaks up the nitrogenous organic compounds in the soil, converting the nitrogen into nitrate of lime, which is a readily soluble, and easily washed away compound. Spring is, therefore, the best season of the year to apply the more caustic forms of lime. Chalk, lime rubble, old plaster, bones, and all the slowly decomposing lime compounds should be applied in autumn, or early winter to afford time for their disintegration.

In some neighbourhoods a very dense clay receives the name of marl, and is much used for top-dressings of various kinds. The effects of such top-dressings are nil, but still they are given. There is yet room for the County Council's education in both agriculture and horticulture in order that a standard of intelligence may be reached to enable the interested to discriminate between the false and the true. Marl is only valuable for heavy soils lacking in lime, of which it contains 20 to 25 per cent. Being a mixture of clay and lime it is admirably adapted for improving the physical and chemical properties of all sandy formations. All our hardy fruit trees and bushes are lime lovers, particularly stone fruits, and, amongst these, especially apricots.

Again, when we scan the country with our mind's eye, and note the diversity of plant life on the various formations, we cannot help profiting by the result. On the limestone we find lily of the valley, daffodils, anemones, violets, campanulas, centranthus, wallflowers, clematis, cyclamen, helleborus, lupins, primroses, and many other useful flowers luxuriating. The scilla, too, is a limestone plant, and this, and those named should have a liberal quantity of lime mixed with the soil in which they are cultivated if there is any lack of this all-important soil disintegrator and plant food constituent.

Pedestrian.

A TASTEFULLY ARRANGED COLLECTION OF SALADING.

For which Mr. E. Beckett, V.M.H., was awarded the first prize at the exhibition of vegetables held by the Royal Horticultural Society, September 26.

Erica gracilis.—This is one of the most popular of market heaths, and also one of the easiest of cultivation. It has a dense twiggy growth, and the slender shoots are thickly studded with tiny rosy-purple blossoms. Of this heath perfect little specimens may be often seen in the florists' shops of London, and even on the costermongers' barrows. The white variety, nivalis, is more constant in colour than was at one time the case, and very pretty and distinct it is. It is sufficiently meritorious to admit of it being generally grown.—W. T.

WORK FOR THE WEEK.

◆

ORCHIDS.

SEEDLING ODONTOGLOSSUMS. — The hot weather of the past summer, although beneficial to many young orchids, has been most trying for odontoglossum seedlings. The seeds sown in many cases in the early spring were most promising, and every indication of a rapid germination was shown, but no doubt owing to a great extent to the dryness of the outside atmosphere, the plantlets, which in the early stages gave so much promise, have been practically at a standstill, and it is only since the recent rains that renewed vitality has been apparent. This has caused more irregularity in the seed beds than usual. The season has arrived for the consideration of such young stock, and with outside conditions favourable, any seedlings that are sufficiently forward to need removal may now be dealt with without delay. I have for many years urged that where there is room the best method is to transfer the young plants to pots of a suitable size to contain them properly, as in their early stages of development they can have their requirements more easily provided when treated separately than can possibly be the case where several are planted together in the same pot. There are scarcely two young plants in a batch of seedlings that have the same vigour; some grow much more rapidly than others, and the weakest plants often perish when all are treated together in the same pot.

HOUSE ROOM.—I am well aware of the difficulties to be met in regard to room after seedling raising has been in practice for a few years. The expense of extra houses and extra labour incurred is generally found a stumbling block, and thus raisers are often compelled to sacrifice a principle found most practical, so as to economise space. I often think of the time when orchid houses were being built extensively and filled with expensive imported plants. How things have changed. We are now able to provide for our requirements from hybridisation at the expense only of labour incurred.

POTTING.—The pots used for seedlings should be clean and filled to about half their depth with clean broken crocks. The compost should be of about equal portions of chopped peat, oak or beech leaves, and sphagnum moss; the latter should be well washed and finely chopped, or it will quickly outgrow and bury the young plants. The leaves should be sterilised to destroy any insects, worms, or fungoid pests before they are used. Add sufficient sand and finely-broken crocks to render the compost porous. The pots should be filled with this compost, and watered some hours previously to use, as this permits the water to drain away before potting the young plant.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

GLORIOSAS.—These will have nearly completed their season of flowering, and attention must be given to the ripening of the tubers. Gradually reduce root moisture, fully expose the foliage, and afford cooler surroundings. After the foliage has become thoroughly ripened off the tubers may be stored in dry sand throughout the winter months. A dry position in a warm greenhouse with a minimum temperature of 50 degrees will suffice for the resting period.

ACHIMENES.—These have ripened their foliage, and the tubers may be now stored underneath the greenhouse stage if a dry position is available, or, should the pots be required for immediate use, they may be successfully stored away in boxes filled with sand and placed in some dry position where frost is excluded.

CALADIUMS.—The latest batch of these ornamental foliage plants will soon be presenting a shabby appearance. As the foliage shows signs of decay less moisture will greatly assist the ripening process. Although a temperature of 55 degrees will generally suffice to winter caladium tubers, I find the more delicate or rare varieties are better stored in the stove where a temperature of 65 degrees is maintained throughout their resting season; C. argyrites and C. minus erubescens are liable to decay if stored in a temperature below 60 degrees. Wherever convenient they should be kept in their pots until the time arrives for starting the tubers into growth again.

EUCHARIS AMAZONICA.—In some gardens it is often particularly desirable to have an abundant supply of blooms for Christmas or thereabouts, and then such choice blooms as eucharis cannot fail to command admiration. Pots of eucharis bulbs that have been resting somewhat in the intermediate stove since they completed their summer growth will now be showing flower spikes, and the most forward plants may be selected and placed in a temperature of 70 degrees, and, where space is available, plunged up to the pot rim in tan bark or cocoanut-fibre refuse. Give a thorough watering with tepid water, and afford a moist atmosphere by occasionally spraying between the plants, and, on favourable opportunities, overhead. After flowering is over the plants will commence to grow freely, and as the foliage attains its full development the ripening off and resting process may be repeated. At no season should the plants be subjected to excessive dryness at their roots, and as they are gross feeders they ought to be always allowed ample pot room. Should, however, circumstances prevent repotting after flowering, and immediately before growth commences, the bulbs may be greatly assisted by frequent applications of farmyard liquid manure and soot water. Where repotting and regular feeding are neglected the deterioration of the stock will result. Mealy bug and scale are often most troublesome, and these pests must be kept in check by frequently sponging and syringing the foliage with some approved insecticide.

VENTILATION.—Very little ventilation will now be required, and as the season advances syringing overhead must be reduced. Artificial heating will now be more needed as the nights become colder, but excessive heating of the hot-water pipes must be guarded against. The temperature of the stove may now range between 65 and 70 degrees, with a few degrees lower on extremely cold nights.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

BEGONIAS. — The tuberous-rooted begonias should be lifted before they are cut down by frosts. It is desirable to allow all growth and foliage to remain on the tubers when lifting, and to store them in a dry airy shed until this decays sufficiently to drop off of its own accord. When this takes place the tubers should be cleaned over, placed in trays, and stored in a cool, dry, airy, frost-proof room for the winter. Here they will remain in good condition until required for starting into growth again. An occasional examination will be necessary from time to time during the winter to prevent any decay or rot spreading, but if the tubers are perfectly dry when put away there will not be much loss. The fibrous-rooted varieties will require boxing when lifted and wintering in a cool greenhouse, where they will keep in good condition until required for division in the spring.

SALVIA PATENS.—Sand will be found an excellent material for storing the tubers in during the resting period, providing the stock is placed in a frost-proof shed. It is a beautiful plant, and every care should be taken to keep the stock sound after lifting. Cuttings, which were put in earlier, and have made small tubers, should be left undisturbed until the early part of the year.

CANNAS.—These are not very difficult to deal with, as they keep in good condition when laid out on the floor of a shed, free from frosts. If there is any doubt about their safety, a few leaves thrown over them will afford all the protection needed.

DAHLIAS may be safely wintered in boxes by shaking leaf-soil amongst the tubers after they are packed in, and placing the boxes where no frost can reach them. When the tubers are lifted the labels must be securely tied on the stems with strong twine, and in many cases it will be necessary to afford new labels before storing.

ROSES.—Old plants which have been in the same position a few years, and are looking somewhat worn out, will regain some of their lost vigour if lifted and replanted. The soil should be taken out of the beds and new soil provided, replacing the plants as quickly as possible. All decaying and dead wood should be cut out, and the roots trimmed a little with a sharp knife.

LAWNS.—Where these have become weedy attention should be afforded them as early as possible. Plantains may be removed with a two-pronged digger, and if large holes are caused by their removal these must be filled in with soil. An application of lawn sand will usually destroy the daisies, but it should be used when the weather is dry.—E. C. Pooley, Gnaton Gardens.

FRUITS UNDER GLASS.

EARLY VINERIES.—In many gardens chrysanthemums are temporarily housed in these structures, and in such cases the part of the border near the pipes must not suffer from lack of moisture. It is not necessary to keep the vine roots wet at this time of the year, but it is quite necessary to prevent them from getting dry, because many of the small or fibrous roots may become injured. See that all necessary root pruning is finished, and at the fall of the leaves all painting or alteration of hot-water pipes should be pushed forward. If the vines have been badly infested with any pest, and subsequently cleansed as directed in a former calender, a couple of coats of paint in the vinery will pretty effectually eradicate it.

SUCCESSIONAL HOUSES containing ripe fruit should now have a little warmth at night, with a current of air at all times; and if the grapes are far advanced towards maturity, they should be cut and placed in bottles of water in the grape room. The laterals should then be shortened to admit of thorough ripening, and the remaining foliage must have a thorough cleaning. At the same time, the roots may require a good watering to help plump up the buds for next season's crop.

LATE GRAPES. — Muscats and Lady Downes, Princess of Wales and Alicante have never been better than this year, but they should have careful treatment if the fruit is to keep well. They must be kept at a very even temperature with a little heat in the pipes when the weather is damp at night. Keep all the laterals from touching the glass, as the moisture from the glass collects on them, and is carried down the shoot into the bunch. Keep the roots just moist, and examine the bunches for decayed berries at least twice a week. Keep the temperature at about 55 to 60 degrees if the grapes are ripe, if not, a few more degrees must be given.

POT STRAWBERRIES.—If the autumn proves wet, means should be taken to prevent the strawberry plants from receiving too much moisture. Some lights should be put over them to keep the rain off.

LATE MELONS.—Give these a temperature of 70 degrees in order to ripen the fruits thoroughly, and keep them dry at the roots, as there should be sufficient moisture in the soil to ripen the crop.

PEACH HOUSES.—Early peaches and nectarines will now be shedding their leaves, and the fall should be assisted by means of a bundle of birch twigs brushed lightly over them. One good recommendation for pot trees is that they are turned out and their places can be filled with flowering plants for a month or two.—W. A. Cook, Leonardslee Gardens.

HARDY PLANT CHAT.

The Amellus Asters.

It is highly pleasing to all of us who have for many years admired the starworts of the type of Aster Amellus to observe the varieties which are now coming so freely to the front, and to witness the increasing popularity of these fine forms, which, in many ways, are so valuable in the garden. An opportunity of seeing a good collection of the newer ones leads one to think that the glorious effects which might be produced in the autumn by groups of these in the hardy plant border have not yet been realised. Some who advocate the formal system of planting could employ them with magnificent effect for bedding or for broad lines in the more artificial autumn effects. What we seem to want now is a very good white one, and it is just within the bounds of probability that we shall have this shortly among the many fine seedlings now being sent out and in the raisers' possession for increase. But we need not wait for this, as we have a great diversity of shade and colour. Beauté Parfait, with fine violet-coloured flowers, is very handsome; the reddish-violet Charles Davis is of a shade which will be useful; and the large-flowered Ultramarine needs only to be seen to be admired for its fine ultramarine violet blooms. Riverslea, no novelty, is yet able to hold its own with its deep violet flowers; and I still like Stella, although its flowers, of a soft slaty blue, are too light and too starry for great effect. Preciosa also maintains its position with its large violet-blue blooms; and the late flowering of Framfieldense makes its violet-blue flowers all the more welcome, seeing that they are about a fortnight after the others. Major, lavender-blue, is also excellent. Of the pink and rose shades, so useful, we have Perry's Favourite, a beautiful rose-coloured Amellus Aster, and Distinction, with fine masses of rose-lilac blooms. These are some of a good number I have seen in first-class condition this autumn.

Aconitum cæruleum.

I should much like to know if it is absolutely certain that this new monkshood is really, as has been said, a seedling of Aconitum Wilsoni. I am disposed to accept the statement that it is, until I have evidence to the contrary, although I am assured by a good hardy plantsman that it is the same as one sent out some time ago as A. septentrionale, which, by the way, I have not seen for a long time, so that I cannot compare the two. But Mr. G. Gibson, of Leeming Bar, who is sending the new one out would, I think, be well enough acquainted with A. septentrionale to know if his one was the same. The colouring is, so far as my recollection of A. septentrionale goes, much the same—a light violet-blue—but the habit of this new one is apparently the same as that of A. Wilsoni, of which it is said to be a seedling. There is no inherent impossibility in this, as the latter probably varies at home in shade of colour, and the sport from seed into a lighter colour under cultivation is quite a probable thing. I am told that some doubt A. cæruleum remaining true to colour, but there is no reason why divided plants should revert to the original colouring, and plants of this class are generally remarkably constant when raised, as this one has been, if propagated by division afterwards. A. Wilsoni is so useful for autumn bloom that the lighter-coloured counterpart is welcome.

Potentilla atrosanguinea Gibson's Scarlet.

The mention of Mr. Gibson reminds me of a potentilla, called Gibson's Scarlet, which attracted my notice a short time ago, when the plant began to find its way into gardens. It is undoubtedly a very fine flower, the colouring being the most brilliant of all the shades of scarlet we have among the potentillas. Vivid scarlet—the description given of the tint—is by no means an exaggeration of the colour, and we have few brighter things in its way. As it only grows about a foot high, it is a good thing for the border, but I think it shows its real value on the larger rockeries. Like many other potentillas, it objects to being in a place where it is burnt up for want of moisture, and a cool position gives it even greater brightness than when it is exposed to the full glare of the sun.

S. Arnott.

VARIEGATED HART'S-TONGUES.

It has often been doubted whether there are really any thoroughly constant variegated varieties of hart's-tongue, so many instances having occurred of reversion on the one hand, and, on the other, of induced and temporary variegation, due to unfavourable conditions of culture, or exposure to sunshine. Finds have been repeatedly recorded of well-marked variegation, but subsequently it has always been difficult to find surviving specimens in collections, and the opinion has therefore become fairly general that the phenomenon is only temporarily manifested, and is not a constant feature capable of being permanently maintained, and even transmitted through the spores.

Variegation in any case is a very rare occurrence in our native species, though in exotic ferns, such as Pteris cretica albo lineata, Pteris argyrea, and P. tricolor, we have really definite cases. In British ferns we have Polystichum angulare inequale variegatum of Padley, which has its fronds constantly pervaded with white pinnules, giving it a distinctly speckled appearance, the "inequale" feature, which is not marked enough to detract from its beauty, being due to the diminished size of the white pinnules, owing, presumably, to paucity of chlorophyll. This fern succeeded in imparting its form of variegation exactly to a polydactylous angulare with which it was crossed. Another, and more beautiful, constantly variegated fern is the rare aposporous P. angulare pulcherrimum of Moly, in which the large falcate pinnules are symmetrically coloured a bright golden-yellow on the lower half, and normal green above. This has yielded true offspring by apospory in Dr. F. W. Stansfield's hands, though the bulk of such offspring presented the usual ragged and imperfect forms, common, apparently, to all the progeny of the aposporous "angulares."

An athyrium, offspring, we believe of A. ff. percristatum Cousins, has its fronds mottled with very light green, almost white, and normal green in an erratic marbled fashion. This was noted by the writer in a garden at Kew, where numerous ferns from his own collection had found a home, hence the presumption of Cousinsi origin. In Mr. Cranfield's collection, largely increased by his acquisition of the remains of Mr. Moly's, there is an angulare, the history of which is not recorded, with fronds showing pure snow-white portions.

To return now to the question of the hart's-tongue, our object is to place on record a curious case of apparently contagious variegation of a probably permanent character, which has occurred recently under our own observation. A year or two ago, when fern hunting in Devonshire with Mr. Cranfield, we both found, on different sides of the same lane, specimens of otherwise normal hart's-tongues, all the fronds of which were irregularly striped with dark green on a yellowish ground, a feature which, both in his case and ours, has proved constant. In the same week the writer came across three other hart's-tongues of the purely normal green colour, but one bore muricate narrowed fronds, and the other two, though separately found, had their fronds contracted and deeply crenated for a short distance near the basal lobes. All four plants were installed in a nine-inch square pan, and placed near a well-lighted north window. As a result they thrived so well as to form good-sized plants, and fill the pan tightly with their intermingled roots.

Last spring, owing to their need of more root room, they were turned out en masse into the garden, and the square solid mass, undisturbed, was dropped, plants and all, into the soil, only the pan being removed. At that time the variegated specimen occupying the centre alone showed its striped character, the others being normally green, as found. To our intense surprise, however, when the new growth arose, which it vigorously did with all four plants, as it matured, all four presented the same distinct striped markings on a light yellow ground, precisely like the central one, and at the time of writing the four plants represent a clump of variegated hart's-tongues, though the three originally plain ones still show the characteristic variations above described, thus entirely precluding the assumption that they had perished, and that the entire variegated clump consisted of the originally variegated find alone.

In this connection we may mention that the late Mr. G. B. Wollaston, of Chiselhurst, one of our foremost pioneers of the British fern cult, had also a collection of many curiously variegated plants, ranging from common weeds to umbrageous trees, and he was quite confident that variegation was in many cases imparted from one plant to another if grown so that the roots became closely intermingled, a theory which we hardly felt inclined at that time to accept. The case, however, which we have cited goes very far to prove that, at any rate, there is something in it, since it will be noted that it is not merely a case of that tendency to produce yellow fronds due to exposure to hot sun which the hart's-tongue often shows, but one in which the distinctly striped character of the central plant is displayed clearly in the associated varietal ones, which were perfectly green when discovered, while other varieties close by, but beyond reach of the presumably infecting roots, are normally coloured.

We have thought it well to record this case in detail as it opens up a most interesting field for experiment. Mr. Wollaston was a very keen observer, but, unfortunately, did very little in the way of publishing records of systematic investigation for demonstrable proofs, but we retain a very vivid recollection of his pointing out to us numerous instances of variegation which he asserted had arisen by sowing seeds of other non-variegated plants, even of trees, in beds of variegated cress and similar small vegetation, such seeds eventually producing growths variegated on the same lines, though derived from plants of normally coloured foliage. Experiment on these lines is not difficult, but it is all-essential that they be made on definitely recorded lines to be of value.

C. T. Druery, V.M.H., F.L.S.

GREAT EXHIBITION OF BRITISH-GROWN FRUIT.

(Continued from page 754.)

kets of Newton Wonder, Rival, Wealthy, Peasgood's Nonsuch, Bramley's Seedling, and Ribston Pippin apples, and fine examples of Marguerite Marillat, Gross Calebasse, Doyenne du Comice, Directeur Alphand, Princess, Uvedale's St. Germain, Doyenne Boussoch, Beurre Clairgeau, Conference, Louise Bonne of Jersey, and Marie Louise d'Uccle pears. Mr. R. C. Notcutt, Woodbridge, was awarded a silver Knightian medal for a good collection, in which populaar apples were staged in large baskets.

For a display 12ft. by 6ft., Messrs. G. Cooling and Sons, Bath, gained the silver Knightian medal with a very nice collection, wherein a good basket of Pitmaston Duchess pears was a fine feature; Messrs. Daysh and Wright, Queen's Park, Alton, gained a silver Banksian medal; Messrs. Paul and Son, Cheshunt; Messrs. W. Spooner and Son, Hounslow; and Messrs. John Peed and Son, Norwood, were other exhibitors in this class.

There was but one entry of nine vines in pots, and this from Messrs. T. Rivers and Sons, Sawbridgeworth, amply demonstrated this excellent and useful method of culture. The vines carried a good crop, and the varieties were Alicante, Golden Queen, and Gros Colmar.

For orchard house fruit and trees Messrs. T. Rivers and Son, Sawbridgeworth, won the gold medal with a grand lot of trees, splendidly fruited; particularly good were the crops of Pitmaston Duchess, Durondeau, St. Edmund, and Conference pears, Gascoyne's Scarlet, The Houblon, Jas. Grieve, and King of Tompkin's County apples; and President plums. Among the picked fruits we noted large and superbly-coloured specimens of Emperor Alexander, Cox's Orange Pippin, Lady Henniker, Peasgood's Nonsuch, and Reinette Descardre, and Doyenne du Comice, Magnate, Marguerite Marillat, Duchesse d'Angoulême, and Souv. du Congrès pears; Salway peaches, and Coe's Golden Drop plums. The silver-gilt Hogg medal fell to the King's Acre Nurseries, Lim., Hereford, for a group of very heavily-cropped apples and pears; among the former were examples of Gloria Mundi, Allington Pippin, Twenty-ounce, and Cox's Orange Pippin apples; while of pears the trees of Glou Morceau, Beurre Diel, Le Lectier, and Marie Benoist were especially attractive. Along the front were dishes and baskets of picked and selected fruits of popular apples and pears, many of them very highly coloured.

MARKET GROWERS' CLASSES.

In this division the best score of baskets of cooking and dessert varieties shown by market growers came from Mr. R. A. Whiting, Faversham, who was awarded a gold medal for a magnificent set, in which we noted Warner's King, Peasgood's Nonsuch, Stone's, Lord Derby, Rival, Cox's Orange Pippin, Allington Pippin, Royal Jubilee, Houblon, Blenheim Pippin, Charles Ross, and King of the Pippins; Mr. H. T. Mason, Hampton Hill, Middlesex, was second, and gained a silver-gilt Hogg medal for a grand set that included magnificent baskets of Cox's Orange, and Allington Pippins, and Coronation; third prize fell to Mr. E. W. Caddick, Caradoc, Ross, for a good set; the silver-gilt Banksian medal was awarded.

The silver-gilt medal of the Fruiterers' Company for a dozen baskets of apples was won by Mr. A. E. Mason with a grand set of Peasgood's Nonsuch, King of the Pippins, Allington Pippin, Yellow Ingestre, The Queen, Newton Wonder, Cox's Orange Pippin, Lane's Prince Albert, Bismarck, Jas. Grieve, Beauty of Kent, and Ribston Pippin; the Horticultural College, Swanley, second, winning a silver Knightian medal. Mr. H. Lumley Webb, Sittingbourne, was third, and secured a silver Banksian medal.

SINGLE DISH CLASSES—DESSERT APPLES.

In the following sections the schedule gives a list of varieties to be shown. A single dish of six fruits is required, and two prizes, respectively 7s. and 5s., are offered. We give the name of the variety and of the first prizewinner, and also the number of dishes staged in competition:

Adams' Pearmain, Mr. T. H. Bolton, gardener to the Earl of Devon, Powderham Castle, Exeter; nine entries. Allington Pippin, Mr. J. C. Sutton, Chevening; twenty-three entries. American Mother, Mr. J. Bond, Wye; fifteen entries. Belle de Boskoop, Mr. A. Basile, Woburn Park Gardens, Weybridge; four entries. Ben's Red, Mr. E. King, gardener to R. Lamber, Esq., Aylesford, Kent; two entries. Blenheim Orange, Mr. C. O. Walters, Ickleton House, Wantage; twenty-eight entries. Charles Ross, Mr. F. King, gardener to Rev. H. A. Bull, Westgate; nine entries. Christmas Pearmain, Mr. B. J. Mercer, gardener to H. G. Kleinwort, Esq., Wierton Place, Maidstone; nine entries; Claygate Pearmain, Mr. H. C. Gardner, gardener to Lord Foley, Ruxley Lodge, Claygate; eleven entries. Coronation, Mr. J. Copp, Ferndale, Teignmouth; three entries. Cox's Orange Pippin, Rev. G. H. Engleheart, Denton, Hants; thirty-one entries. Duke of Devonshire, Mr. G. Davison, Westwick Gardens, Norwich; seven entries. Egremont Russet, Mr. J. Bond; nine entries. Houblon, Mr. J. E. Hathaway, Baldersley Park Gardens, Thirsk; two entries.

James Grieve, Mr. F. P. Norbury, Malvern; seven entries. King of Tompkin's County, Mr. F. Brock, Goodwood; seven entries. Lord Hindlip, Mr. R. M. Whiting, Credenhill, Hereford; three entries. Margil, Mr. C. O. Walters, Wantage; five entries. Ribston Pippin, Mr. Herbert Edgell, Hickling, Norfolk; fifteen entries. Rival, Mr. A. Basile, Weybridge; nine entries. Ross Nonpareil, Mr. E. King, Aylesford; one entry. St. Edmund Pippin, Mr. T. Turton, Sherborne Castle Gardens, Dorset; three entries. St. Everard, no entries. Wealthy, Mr. A. Basile, Weybridge; eight entries. William Crump, Mr. H. Brotherston, gardener to the Earl of Lytton, Knebworth, Herts; two entries. Any other early variety, Mr. T. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, with fine King of the Pippins; twenty-four entries. Any other late variety, Mr. A. Andrews, Campsea Ash Gardens, Suffolk, with Fearn's Pippin, grandly coloured; thirty-two entries.

SINGLE DISH CLASSES—CULINARY APPLES.

Annie Elizabeth, Mr. B. J. Mercer; fifteen entries. Beauty of Kent, Mr. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate; seven entries. Bismarck, Mr. J. Vivian, Hayle, Cornwall; twelve entries. Bramley's Seedling, Mr. J. Vivian; twenty entries. Byford Wonder, Mr. J. Lee, Higher Bebington; four entries. Dumelow's Seedling, Mr. C. Page, Dropmore Gardens, Maidenhead; eleven entries. Ecklinville, Mr. J. Bond, seven entries. Edward VII., Mr. R. M. Whiting; three entries. Emneth Early, no entries. Emperor Alexander, Mr. J. Vivian; eight entries. Gascoyne's Scarlet, Mr. G. Davison; eight entries. Golden Noble, Mr. T. Turton; nine entries. Grenadier, Mr. J. Vivian; four entries. Hambling's Seedling, Mr. T. E. Tomalin, Piltown; five entries.

Lady Henniker, Mr. A. Basile; fourteen entries. Lane's Prince Albert, Mr. Thos. Stevenson, Addlestone; fourteen entries. Lord Derby, Mr. B. J. Mercer; eleven entries. Mère de Ménage, Mr. J. Vivian; eight entries. Newton Wonder, Mr. A. Andrews; seventeen entries. Norfolk Beauty, Mr. W. Allan, Gunton Park Gardens, Norwich; four entries. Peasgood's Nonsuch, Mr. A. Andrews; six entries. Pott's Seedling, Mrs. F. W. Platt, View Road, Highgate; three entries. Rev. W. Wilks, no entries. Royal Jubilee, Mr. J. Taylor, Hardwicke Gardens, Shrewsbury; ten entries. Scarlet Victoria, no entries. Stirling Castle, Mr. J. Copp; three entries. The Queen, Mr. J. Bond; eight entries. Tower of Glamis, Mr. T. E. Tomalin; seven entries. Warner's King, Mr. A. Andrews; ten entries. Any other variety, Mr. Gooding, gardener to W. B. M. Bird, Esq., Eartham, Chichester; with Clark's Seedling.

DESSERT PEARS—SINGLE DISHES.

Beurre Alexander Lucas, Mr. A. Basile; five entries. Beurre d'Amanlis, one entry, fruits unfit, no prize awarded. Beurre d'Anjou, Mr. A. Tidy, Cobham Park Gardens; two entries. Beurre d'Avalon, no entries. Beurre Bosc, Mr. A. Basile; five entries. Beurre de Naghan, no entries. Beurre Dumont, Mr. A. Basile; one entry. Beurre Hardy, Mr. A. Allan, Hillingdon Court Gardens, Uxbridge; four entries. Beurre Perran, no entries. Beurre Superfin, Mr. A. Basile; four entries. Blickling, Mr. A. Allan, one entry. Charles Ernest, Mr. A. Basile; four entries. Comte de Lamy, Mr. T. W. Herbert, gardener to J. T. Charlesworth, Esq., Nutfield Court, Surrey; four entries. Conference, Mr. G. Davison; seven entries. Directeur Hardy, Mr. W. Messenger; two entries. Doyenne du Comice, Mr. G. Davison; seven entries. Durondeau, Mr. G. Davison; nine entries. Emile d'Heyst, Mr. S. Barker, Clumber Gardens; eight entries. Fondante d'Automne, Mr. W. Allan; three entries.

Fondante de Thiriot, Mr. A. Allan; two entries. Glou Morceau, Mr. W. Allan; six entries. Josephine de Malines, Mr. G. Davison; ten entries. Le Brun, Mr. A. Basile; one entry. Le Lectier, Mr. Jas. Vert; six entries. Louise Bonne of Jersey, Mr. J. Bond; eight entries. Marie Benoist, Mr. W. Messenger; two entries. Marie Louise, Mr. W. Allan; six entries. Nouvelle Fulvie, Mr. Jas. Hill, Wimborne, Dorset; six entries. Olivier des Serres, Mr. A. Allan; eleven entries. Pitmaston Duchess, Mr. E. King; ten entries. President Barabe, Mr. W. Allan; four entries. Santa Claus, no entries. Souv. du Congrès, Mr. C. Page; six entries.

Thompson, Mr. C. Page; six entries. Triomphe de Vienne, Mr. J. Bond; three entries. Winter Nelis, Mr. H. C. Gardner; nine entries. Any other early variety, Mr. E. Colman, gardener to B. E. Richardson, Esq., Stanstead Abbotts, with Mdme. Treyve; nine entries. Any other late variety, Mr. A. Basile, Weybridge, with Roosevelt, a large, green, brown-speckled fruit of fine appearance; nine entries.

AFFILIATED SOCIETIES.

In the Affiliated Societies Class, the East Anglian Horticultural Club, secretary, Mr. W. L. Wallis, Royal Arcade, Norwich, won the first prize and silver cup, offered for a collection of six dishes each of dessert and culinary apples and pears; the club sent grand dishes of Warner's King, Peasgood's Nonsuch, Bramley's Seedling, Chas. Ross, Houblon, Allington Pippin, and Cox's Orange Pippin apples, and Pitmaston Duchess, Durondeau, Doyenne du Comice, and Hacon's Incomparable pears; the second prize, a silver cup and silver-gilt Knightian medal, fell to the Ipswich Gardeners' Association, secretary, Mr. F. W. Salmon, Brook Hall, Ipswich; the Colchester Gardeners' Association, secretary, Mr. Tanner, East Street, Colchester, gained a silver Knightian medal; six entries.

COLLECTION OF HARDY FRUITS.

Premier award for a collection of hardy fruits, arranged on a space 12ft. by 3ft., fell to Mr. J. Whittle, who added another silver Hogg medal to his collection. Apples and pears were splendidly shown, and there were peaches, blackberries, damsons, prunes, fine plums, nectarines, and quinces, all capitally arranged; Mr. W. H. Bacon gained second prize, and showed Morello cherries, figs, nectarines, plums, peaches, pears, and apples.

FRUIT GROWING.—Full instructions as to planting, pruning, and management of fruit trees are given in PROFITABLE FRUIT GROWING (Ninth Edition) —a gold medal essay by John Wright, V.M.H.—price 1s., or by post 1s. 3d. from GARDENERS' MAGAZINE Office, 148 and 149, Aldersgate Street, London.

BRIGHTON DOME AND CORN EXCHANGE.

29TH GRAND CHRYSANTHEMUM SHOW.
SPECIAL ATTRACTIONS.
ENTRIES CLOSE OCTOBER 25.
Mr. ALFRED GASTON,
Secretary.
Brighton and Sussex Horticultural Society,
Springfield Road, Brighton.

THE BOURNEMOUTH HORTICULTURAL SOCIETY

EXHIBITIONS.
AUTUMN SHOW, OCT. 31st and Nov. 1st, 1911.
SPRING SHOW, MARCH 26th and 27th, 1912.

For schedules and particulars apply to
C. W. BARRETT, Sec., "Lucerne,"
Fenton Road, West Southbourne, Bournemouth.

THE NATIONAL CHRYSANTHEMUM SOCIETY.
GREAT AUTUMN SHOW
will be held
at the CRYSTAL PALACE,
On NOVEMBER 1st, 2nd, and 3rd, 1911.
Entries close October 25th. Write at once for Schedule and full particulars to
RICHARD A. WITTY, 72, Savernake Road, Gospel Oak, London, N.W.

KENT COUNTY CHRYSANTHEMUM SOCIETY.
The 24th GRAND ANNUAL EXHIBITION will be held in the CONCERT HALL, BLACKHEATH, on TUESDAY and WEDNESDAY, October 24th and 25th, 1911.
Schedules and all particulars of the Hon. Sec., F. FOX, The Gardens, The Cedars, Lee, S.E.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

The committees sat on the morning of October 10, but they had very few subjects to deal with; the following awards were made:

FLORAL COMMITTEE.

Award of Merit. — To chrysanthemum Cranford Yellow, a splendid large early-flowering variety from Mr. W. Roots, Holly Cot, Uxbridge; and to decorative dahlia Brentwood Yellow, from Mr. J. T. West, Brentwood, Essex.

ORCHID COMMITTEE.

First-class Certificates.—To Cypripedium Lucifer, a handsome variety from Mr. Alexander, grower to Lieut.-Colonel Sir G. Holford, Westonbirt, Gloucester; to Cypripedium Royal George, one of the very largest and finest of modern hybrids, from Messrs. Armstrong and Brown, Tunbridge Wells; and to Odontioda Euterpe, from Messrs. Charlesworth and Co., Haywards Heath. We understand that Cypripedium Royal George has passed into the collection of Francis Wellesley, Esq., Westfield, Woking.

SCIENTIFIC COMMITTEE, September 26.

Present, Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Dr. A. B. Rendle, F.R.S., Dr. A. J. Voelcker, M.A., F.I.C., Sir Everard im Thurn, K.C.B., J. T. Bennett-Poë, M.A., J. Fraser, F.L.S., J. W. Odell, J. O'Brien, V.M.H., E. M. Holmes, F.L.S., and F. J. Chittenden, F.L.S. (hon. secretary).

OXALIS ORTGIESI.—Mr. J. W. Odell showed a well-grown specimen of this Peruvian species from a cool house at Stanmore in a very floriferous condition. See "Gartenflora" (1875), t. 817.

GALLS ON WILLOW, ETC. — Mr. J. Fraser showed a number of galls on willows and roses and leaves of Ulmus major galled by Schizoneura ulmi, which produces large pouch-like growths on the leaves.

DISEASED PLANTS. — Dr. Voelcker showed specimens of celery attacked by the fungus Septoria petroselini var. Api. This disease appears to be becoming increasingly prevalent each year, and, as pointed out earlier in the year in the minutes of this committee, a considerable number of samples of "seed" of celery are attacked. Probably spraying with Bordeaux mixture or with potassium sulphide from early stages in the plant's growth onwards would keep the disease in check. He also showed cabbage leaves badly attacked by the fungus Phyllosticta brassicæ, causing spotting of the leaves so as to render the plants useless.

REMARKABLE FRUITING OF ÆGLE SEPIARA.—Mr. Bowles showed branches of Ægle sepiara fruiting remarkably abundantly. In most seasons in his garden the earliest flowers are staminate, followed a little later by some pistillate ones, some of which produce fruits, and the crop is a small one. This season, however, most of the flowers were hermaphrodite and practically all produced fruits.

WITCHES' BROOM ON SCOTS FIR.—A remarkable witches' broom on Scots pine was sent by G. W. Ricketts, Esq., of Foulis Court, Eastleigh. It was a dense growth about twelve inches in diameter. The growth was probably due in the first place to the attack on the tree of a species of Æcidium, and it had continued for several years, the leaves on the attacked portion being smaller in size than those on the normal shoots.

RUBUS INNOMINATUS (S. MOORE).—Some fruiting shoots of this newly-introduced rubus, from China, were shown by the Hon. Vicary Gibbs, under the name of Rubus Kuntzeanus. The fruits are insipid, small, and amber and black in colour. The two names are synonymous.

National Sweet Pea Society.

The following account of the proceedings of the N.S.P.S. Floral Committee for 1911 has been sent us for publication by the hon. secretary, Mr. Chas. H. Curtis:

AWARDS.

First-Class Certificates.—To Trial No. 119 (Thomas Stevenson, Dobbies', sent by Messrs. Dobbie and Co. The silver medal was awarded, provisionally, to this trial). Trial No. 111 (Barbara, sent by Mr. Robert Holmes, Tuckswood Farm, Norwich; raised by Mr. H. A. Perkin, Reigate).

Awards of Merit.—To Trial No. 33 (F. Seymour Davis, sent by Mr. F. Seymour Davis, Farnham). Trial No. 43 (Mauve Queen, sent by Messrs. Dobbie and Co., Edinburgh). Trial No. 138 (Red Star, sent by Mr. A. Malcolm, Duns, Berwick). Trial No. 211 (May Campbell, sent by Messrs. Dobbie and Co., Edinburgh). Trial No. 212 (Mrs. B. Gilbert, sent by Messrs. Gilbert and Son, Dyke, Bourne).

RECOMMENDATIONS.

The Floral Committee strongly recommends:

(1) That twenty seeds be sent for each individual trial in 1912, fifteen plants to be set out in a row twelve feet long.

(2) That raisers be notified if less than fifteen germinate, and a request made for more seeds.

(3) That failing seeds, seedlings about three inches high be accepted to make up the number of plants.

(4) That on the first visit to the trials in 1912, varieties be selected for voting upon at the subsequent visit; no voting to take place at the first visit.

(5) That a duplicate set of trials be conducted in 1912, on heavy soil, at least 100 miles north of London; and, in the event of this recommendation being adopted, the Floral Committee pay one visit only to each set, point each stock, and make its awards on the results thus arrived at. Under these conditions a scale of points would be prepared prior to the first visit and all stocks obtaining a certain aggregate of points would be voted upon.

(6) That the raiser's description be furnished in the case of varieties which gain awards, and that such description be included in the proceedings of the Floral Committee.

(The General Committee of the N.S.P.S. approves the foregoing recommendations, and will endeavour to give effect to them.)

Bournemouth Gardeners' Association.

There was a very fine exhibition of apples and gourds at the fortnightly meeting on Tuesday, October 3. Mr. Nippard, head gardener to J. J. Norton, Esq., Ashton Court, staged some beautiful dishes of apples. One perfect specimen of Peasgood's Nonsuch weighed one pound five and a-half ounces: it was of even shape and well coloured. He had also grand dishes of Cox's Orange Pippin, Gascoyne's Scarlet, Bismarck, and Warner's King. Mr. Charles Pearce, gardener to Mrs. Ormond, had very fine specimens of Cellini, and Mr. W. Reeves staged various gourds and cucumbers. The snake cucumber, red and yellow Turk's Cap, Hedgehog, Ostrich, yellow and green top pear and orange gourds, were all very pretty. The same exhibitor staged Emperor Alexander and Lord Derby apples.

The subject for discussion was "Seeds versus Cuttings." It was very ably opened by Mr. Nippard, who said that no doubt many kinds of plants were stronger, and in every way better, when raised from seed; but there were other kinds which could not very well be raised from seeds, and these must be propagated by cuttings. He referred to Mr. Crook's contention that Salvia patens would not do at all well after being propagated by cuttings for three years, and that it was advisable to raise fresh stock by seeds every third year, and, in turn, to propagate again by cuttings from it. Having instanced several other cases, and admitting that seedlings were more vigorous than cuttings, Mr. Nippard said that zonal pelargoniums, fuchsias, and several other kinds of plants had, of course, been propagated by cuttings for many years, and yet the stock retained its vigour. Chrysanthemums from cuttings, and rhubarb and seakale from thongs, deteriorated, and it was necessary to raise new stock from seeds occasionally. Potatoes also became diseased and worn-out, whereas crotons, dracænas, and Begonia Gloire de Lorraine, kept their vigour when propagated by cuttings and stem slips for a long time. A very good discussion then followed, in which Messrs. Pearce, Stevenson, Garner, King, Heath, Reeves, and others took part, and all felt that the subject was one that could not be exhausted at one, or even two, meetings, and that it needed to be thoughtfully dealt with. Hearty votes of thanks were accorded both Mr. Nippard and the chairman, Mr. Taylor.

Scottish Horticultural Association.

The October meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 3rd inst. Mr. Massie, the president, was in the chair, and there was an attendance of 105 members.

A conference and discussion on early-flowering chrysanthemums was the subject, and a fairly good representation of these was on the table, the contributors being Messrs. Dobbie and Co., Messrs. Todd and Co., Mr. John Downie, and Mr. James Bruce. Mr. Berry, of the Edinburgh and East of Scotland College of Agriculture, opened the discussion, and the other speakers were Messrs. Cuthbertson, Todd, D. W. Thomson, Bruce, Wood, Smale, Fraser, Proctor, Porter, Taylor and Miss Burton. There was difference of opinion regarding the merits of the single early flowering kinds, but all agreed that they were not so fine as the late flowering singles grown under glass. Mr. Todd thought early flowering chrysanthemums were a nuisance as early as June; the middle of September was soon enough for them; and both he and Mr. Cuthbertson drew attention to the earlier large flowering varieties, which were being so extensively cultivated by some growers near London for market use, Mr. Cuthbertson remarking that he had seen a break of a dozen acres of these so arranged in blocks that, by means of light framework, they could be covered with glass. As was to be expected, there was some difference of opinion as regards the time of taking the cuttings and putting out the plants, Mr.

Smale mentioning that he had seen a very fine lot this season which had been planted out in the beginning of June. The general opinion, however, seemed to be that the end of April or beginning of May was the best time to plant out.

In a communication from Mr. W. Wells, Merstham, he stated that early-flowering chrysanthemums were a total failure this season in the South of England, and he mentioned the interesting fact that the variety Leslie was the only one which had not been injured by the heat and drought. The speakers received a hearty vote of thanks on the motion of the Chairman, and a similar compliment was paid to the exhibitors. On the suggestion of Mr. Cuthbertson, the members and others were invited to send in to the secretary the names of what they considered the best twelve early-flowering chrysanthemums, and that these be tabulated and published. The other exhibits consisted of new collarette dahlias, and a new early flowering chrysanthemum named Cynthia, from Messrs. Dobbie and Co. The following awards were made by the Adjudicating Committee: First Class Certificate to collarette dahlias, Holyrood and Prince Charlie; and Certificates of Merit to collarette dahlias Diadem, Prince de Venosa, and Maurice Rivoire. At the meeting on November 7, Mr. W. Roadley, Comb Bank Nursery, Edinburgh, will read a paper on "Propagation." Six new members were elected.

METEOROLOGICAL OBSERVATIONS.

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price **10/6.** Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

SELF-SOWN CRYSANTHEMUMS.—R. C., Wokingham: Strong, sturdy seedlings from self-sown seeds will stand the winter quite well in most cases. If the position is suitable simply thin out the seedlings to a foot or eighteen inches apart, but if it is desirable that these annual chrysanthemums should flower in another spot, then transplant them at once, lifting each one with a trowel so as to retain as much soil as possible about the roots. Plant firmly and water in if the soil is at all dry.

EVERGREEN CLIMBER FOR CONSERVATORY WALL.—W. N. C., Colchester: There are many subjects suitable for the wall at the back of a lean-to conservatory, facing due south, but which would be best for the hot position suggested depends largely upon the size of the conservatory. Lonicera sempervirens, Clematis indivisa lobata, Cestrum aurantiacum, and C. Newelli are all excellent. We have a weakness for pelargoniums on such positions, because the narrow borders and the sunny aspect tend to prevent gross growth, and at the same time produce freedom of flowering. Many of the older zonal varieties may be trained to cover such a wall, and they will give blooms all the year round; ivy-leaved varieties may also be used, notably Galilee and Souv. de Chas. Turner. If a flowering plant is not essential, then the neat little Ficus repens will do very well, as in a few years it will clothe the wall with a close, dense mass of small green leaves, and only need an occasional clipping to keep it neat.

MARGUERITE CARNATIONS.—L. C., Rugeley: The plan of lifting, potting, and housing marguerite carnations after they have been flowering for a considerable period is not an altogether satisfactory one, because the lifting is a considerable check to plants that are usually full of growth in late autumn. This succulent growth is not likely to stand the confinement of a warm greenhouse, although we have seen such lifted plants producing a number of flowers in some places. A better plan is to sow some seeds late in the spring, pot the seedlings as necessary, eventually placing them in 48's or 32's, and plunging them out of doors. So treated, growth will not be excessive, and it will yield blossoms well into the winter if a warm greenhouse temperature is provided.

SECKLE PEAR.—E. B., Elstow: The free-bearing October dessert pear named Seckle is of American origin. The late Mr. Chas. Downing, a great American pot pomological authority, states that "The precise origin of the Seckle pear is unknown. The following morceau of its history may be relied on as authentic, it having been related by the late venerable Bishop White, whose tenacity of memory is well known: About 1765, when the Bishop was a lad, there was a well-known sportsman and cattle dealer in Philadelphia who was familiarly known as Dutch Jacob. Every season, early in the autumn, on returning from his shooting excursion, Dutch Jacob regaled his neighbours with pears of an unusually delicious flavour, the secret of whose place of growth, however, he would never satisfy their curiosity by divulging. At length, the Holland Land Company, owning a considerable tract south of the city, disposed of it in parcels, and Dutch Jacob then secured the ground on which his favourite pear tree stood—a strip of land near the Delaware. Not long afterwards it became the farm of Mr. Seckle, who introduced this remarkable fruit to public notice, and it received his name." The Seckle pear was sent to this country in 1819 by Dr. Hosack, of Philadelphia, along with several other fruits, to the garden of the Horticultural Society, then at Ealing.

BUSHEY PARK AVENUE.—L. A. G., Andoversford: Writing from memory, and at the moment of going to press, we believe the fine old avenue through Bushey Park consists of a double row of horse chestnuts on each side of the broad roadway, and a double line of lime trees on the outer side of each double row of chestnuts. We agree that an avenue of purple beeches would be novel, but we have some doubt as to its ultimate success, because, unless the position and surroundings are light and bright, such an avenue would be rather sombre. We should prefer an avenue of common beech, because of its grace and its fine autumn colouring.

BEST OUTDOOR PEACHES.—D. A. S., Epsom: In the present issue we publish an excellent article on outdoor peaches from the pen of Mr. Thomas Coomber, The Hendre Gardens, Monmouth. Mr. Coomber is an especially clever fruit grower, and he manages outdoor peaches uncommonly well in a garden where situation and soil are both against their culture, therefore his opinion of the merits of varieties is worthy of every consideration.

SALTWORT.—R. O., Guernsey: The low-growing, rigid herbaceous plant known as Saltwort is Salsola Kali. It is widely distributed along the sandy seashores of the British Isles, Channel Islands, the Mediterranean coasts, and even in India, South America, and Australia. It is a salt-loving plant, and rarely thrives away from the seaside. It has no value as a garden plant, but years ago it used to be collected in districts where found plentiful, and burnt to produce the ash known as Barilla, which, however, may also consist of the ash of seaweeds. Salsola soda, an annual species found in the Mediterranean region, is a source of carbonate of soda, and was a plant of some importance economically before the manufacture of soda from common salt. It is probably from the Arabic word "Kali," given to the ashes of soda or salt plants, that the general term of "alkali" has been derived.

SWEET PEAS.—F. C. C., Arundel: "Sweet Peas and Their Cultivation," by Mr. C. H. Curtis, and published at 1s. 2d., or 1s. 8d. post free, from the Gardeners' Magazine Office, 148 and 149, Aldersgate Street, E.C., is the most useful and interesting book on the subject. A new edition will be published shortly with many new illustrations, and an up-to-date selection of varieties.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

S. H., Cuckfield.—Luculia gratissima.

M. C. W., Reigate.—Trichosanthes anguina.

W. H. L. H., Leeds.—Apparently a piece of an Aloe leaf.

P. R., Amesbury.—1, Köelreuteria paniculata; 2, Rubus phœnicolasius.

W. F. R. C.—Very poor specimen; probably a small Solanum melongena.

S. C. J., Chester.—1, Hoya carnosa; 2, Cissus discolor; 3, Vitis labrusca; 4, Monstera deliciosa.

NAMES OF FRUIT.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

C. N., Buckden.—1, Golden Noble; 2, Worcester Pearmain.

F. E. S., Hertford.—1, Durondeau; 2, Warner's King.

C. F. M., Eltham.—1, Beauty of Kent; 2, Worcester Pearmain; 3, not recognised.

G. G. B., Basingstoke.—1, Warner's King; 2, Lane's Prince Albert; 3, King of the Pippins.

R. B., Worksop.—1, Gloria Mundi; 2, Cox's Orange Pippin; 3, Newton Wonder; 4, Dumelow's Seedling.

R. T., Newbury.—1 and 2, quite smashed up in the post; 3, Marie Louise; 4, Durondeau; 5, Beurre Clairgeau.

GARDENING ENGAGEMENT.

Mr. David Airdrie has been appointed land steward at Shield Hall, the Lanarkshire estate of Sir Nathaniel Dunlop, where extensive improvements, including planting and hothouse construction, are in contemplation. Mr. Airdrie is well kown in Scottish horticultural circles, and while at Larbert House he was a frequent exhibitor of grapes at the Royal Caledonian Horticultural Society's shows.

CATALOGUES RECEIVED.

GEORGE BUNYARD AND CO., LIM., MAIDSTONE.—The new catalogue of fruit trees and roses for 1911-12-13 is as complete and up-to-date as its predecessors. It opens with a handsome plate of Baumann's Winter Reinette apple, reproduced from a photograph in colour.

BARR AND SONS, COVENT GARDEN, W.C.—Daffodils, from the cheapest sorts for woodland and lawn planting, up to the newest and most expensive for the fancier are listed in this new catalogue. On the front page is the important announcement that the firm's nurseries are now at Taplow, Bucks, instead of at Ditton.

AMOS PERRY, ENFIELD.—A selection of choice climbing plants and shrubs is given in connection with a comprehensive catalogue of bulbs and tubers. In a separate catalogue of a dozen pages delphiniums are described at length, and a coloured plate of five distinct varieties is inserted.

H. CANNELL AND SONS, SWANLEY.—Autumn catalogues are almost as numerous as autumn leaves, and they come in company with the later bulb lists. One, devoted to fruit trees, roses, trees, and shrubs, and hardy flowers, reaches us from Swanley, and it is an excellent guide to all these subjects.

WHITELEGGE AND PAGE, CHISLEHURST, KENT.—In this catalogue of French, Dutch, and Japanese bulbs a most rigid selection of varieties is shown, consequently the amateur is not puzzled as to which are the best in the various colour groups of tulips, hyacinths, etc.

FORTHCOMING ENGAGEMENTS.

WEDNESDAY, October 18.—North of England Horticultural Society, at the Town Hall, Leeds; Exhibition with Lecture by Mr. H. Somers Rivers on "Fruit Growing in Orchard Houses," the latter to commence at 3.30 p.m.

MONDAY, October 23.—National Chrysanthemum Society; Floral Committee at 3 o'clock at Essex Hall, Strand; General Committee at 7 o'clock at Carr's Restaurant, Strand.

Situations Wanted.

GARDENER (Head Working).—H. ESSAM can with confidence recommend his Foreman, where several are kept; life experience in all branches; age 31; married when suited; excellent references. Address, Closes Hall, Gisburn, Clitheroe.

GARDENER (Head or Single-handed); life experience, Flower, Fruit, and Vegetables; married, no family; age 27; good references; life abstainer. VINALL, Terry Villa, Knaphill, Woking.

GARDENER (Head Working).—Mr. WATSON can highly recommond C. WALLIS, where two or three are kept; been here six years as Second of five; age 31; married, two children. The Gardens, Bushey Down, Tooting Common.

GARDENER (Head of two or more) seeks RE-ENGAGEMENT; life experience, Inside and Out; 23 years Head in last place; good references. J. KIGHTLEY, Roade, Northamptonshire.

GARDENER (Head Working) seeks RE-ENGAGEMENT; thoroughly experienced all branches; 5 years as Head; energetic; highest references; age 32; married. WARNER, Road Manor Gardens, Bath.

HEAD GARDENER, where several are kept, seeks SITUATION; well up in Gardening in all its branches, and understands Stock; 9 years' excellent character and several good testimonials of previous places. F. J. ASHDOWN, Chiddingfold, Surrey.

GARDENER (Head Working) seeks SITUATION, with 2 or 3 under; life experience with Vines, Peaches, Melons, Flowers, and Vegetables; married, one child. J. PETTY, Marchwood, Southampton.

GARDENER (Head), life thorough experience, Fruits, Flowers, Vines, Peaches; Inside and Out; thoroughly understands Roses, Herbaceous Borders, Lawns, Trees, Flowering Shrubs; excellent character; 4 years Outside Foreman; 3 years Head Working Gardener; left through death; married; age 33; three children. HUDSON, Cupid Green, Hemel Hempstead.

GARDENER (Head, where several are kept); thoroughly experienced in all branches Inside and Out; Grapes, Peaches, Melons, Stove and Greenhouse Plants; 4½ and 11 years' excellent references as head; married, family out. E. STONE, 13, Coulston Road, Addiscombe, Croydon, Surrey.

GARDENER (Head Working); 17 years' experience in all branches; 5 years Head; age 34; married, one child; good references. SELLER, 49, Carnot Street, Leeman Road, York.

GARDENER (Head Working).—CAPTAIN USHER highly recommends R. Appleby as above; life experience in all branches; thoroughly understands Planning and Laying Out; also Land and Stock; many years' excellent character. Address APPLEBY, c/o Mrs. Eggleton, Haslemere, Mill Down Road, Goring-on-Thames.

GARDENER (Head Working).—Mr. R. W. Williamson, of the Croft, Didsbury, near Manchester, strongly recommends his late gardener, HENRY ARNOLD, who has been with him for over 20 years, is well experienced in gardening in all its branches, and is specially trained in rockery construction and cultivation of alpines.

GARDENER (Head Working) requires SITUATION; thoroughly experienced all branches; married, no family, highly recommended; disengaged. W. H., 3, Gipsy Lane, Wokingham.

GARDENER (Head Working, where one or 2 kept); 16 years in present situation; 5 years as Second; age 31; single. Apply A. GIBBS, 8, Pope Road, Bromley, Kent.

GARDENER (Single-handed, or where help is given); 17 years' experience, Inside and Out; age 32; married, no family; good references. G. EUDEN, 11, Clifton Road, Spring Grove, Isleworth.

GARDENER (Single-handed, or where help is given); 12 years' practical experience; 4 years in last situation, good references; single; age 36; abstainer. J. CHAPMAN, Ferry Hill, Chatteris, Cambs.

GARDENER, 40; Single-handed preferred; thoroughly experienced; excellent character; active worker; Inside and Out, with early vegetables; abstainer, married. A. BISHOP, Windmill Hill, near Hailsham.

GARDENER (good Single-handed or otherwise); life experience; good all-round Man in all branches; aged 45; married, one child; would take very moderate wage with cottage for a comfortable place. Excellent testimonials; willing to be useful. F. OSBORNE, 48, Bradshaw Road, Watford.

GARDENER (Second, Inside or Inside and Out), 16 years' good all-round experience; age 31, excellent references. W. PACKHAM, The Gardens, Moonhill Place, Cuckfield, Sussex.

JOURNEYMAN (Third), three years present situation, age 20. SYDNEY DRURY, Ivy Hatch, near Sevenoaks.

JOURNEYMAN seeks SITUATION, Inside and Outside, eight years' experience, good references; age 24. HALES, St. Dunstans Gardens, Regent's Park, N.W.

MR. H. EDWARDS, Norton Priory Gardens, Chichester, will be pleased to recommend CHARLES GUDDLE as Journeyman, Inside and Out; has been six years as Journeyman on Pleasure Grounds and in Kitchen Garden, strong, willing, and anxious to improve himself. Home Counties preferred; age 20.

D. SKINNER, Head Gardener Lord Barrymore's Estate, Cordangan Gardens, Tipperary, Ireland, strongly recommends M. Coffey to any Gardener requiring good Man for Pleasure Grounds and Kitchen Garden; age 24; married. Please address, COFFEY, 35, Bridgewater Street, Deansgate, Manchester.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Reproduction.

The study of the many methods of reproduction which have been evolved since organic life was first originated upon the earth's surface is an absorbing one indeed. Originally, i.e., as exemplified in its presumably primal form of mere multiplication and separation of individual cells, it appears simple enough, though, in point of fact it is inconceivably complex.

The cell, the primary basis of all life, consists but of a mere sac or minute bladder filled with a somewhat viscous fluid, in which is suspended a microscopic body termed the nucleus, and it is really within that tiny body that all the vital energy of the organism is pent up. If we watch it we may see that tiny dot split up into two, the two portions will then separate, and between them a wall will be created, the divided cell then perfecting each division into a perfect cell, so that instead of one there are two. In some of the lowest organisms these separate, and in this way the simplest types are reproduced, or, rather, multiplied. In the more highly organised beings the cells do not thus separate, but are aggregated together to form the limbs, bones, and muscles, etc., of the animal kingdom, and the roots, branches, fruits, etc., of the vegetable kingdom, the cells, though multiplying in the same way, having the power of altering their character and secretions so as to suit the various structures they form or offices they fulfil. This sort of multiplication, however, cannot be termed reproductive, since it merely tends to perfect the individual organism but not to increase its numbers. At some early period in the great scheme of evolution the mere multiplication by fission or separation of the individual cell units was abandoned where the structures became complex and their functions distinct. The original simple cell, as we may see to this day in the Amœba, could perform all its vital functions of reaching, absorbing, and digesting food, and when it divided as described, both individuals possessed of a nucleus could do the same. The highly organised individual, however, provided with a special stomach, and means of locomotion, etc., would obviously, if divided, be incomplete, although it might, to some extent, be capable of self-repair, as we see in the Hydra, and even more highly organised creatures. Early, however, in evolutionary history, the great principle of reproduction by the conjunction of the separate potencies of two individuals came in as a mighty factor in the upward march of life. It was ordained that both in the plant and animal world, as a rule, there should be an alliance effected in such a way that the new generation should not practically be parts of the same individual, as is the case by mere fission or severance of parts, but an actual combination of two separate ones, and this led to the establishment in course of time of two different sexes. In this way differences, constitutional and other, induced by different environments, became commingled, and by such commingling of varied potencies an immense impulse was undoubtedly given to that variation in the offspring, which has led up to the wonderfully diverse forms of orders, genera, species, and varieties with which we are partly familiar in these days. In the plant world, with which we are more particularly concerned, we are blest with a far greater facility for reproduction than exists in the animal world, at least, in that part of it with which we are more immediately in touch (cattle, sheep, etc.), since plants still retain the power of yielding new individuals by fission of their parts (cuttings, buds, etc.), owing to their simpler structure. In a plant every twig is a potentially independent individual by possessing the power of generating roots at its base if severed and planted; and, in some cases, as in begonia leaves, or where the bark of a tree is wounded, it is clear that the formative cells at any point are capable of abjuring their usual local functions and adopting reproductive ones instead, in case of need. In the familiar animal world we have nothing akin to this; the lizard may regrow a snapped tail, but the snapped tail will never produce a new lizard. It is, however, in the direction of that sexual reproduction to which we have alluded that we are most indebted to plant evolution. Here we have the marvellous separation of the two potencies into those of the pollen grain and those of the ovary, and their eventual conjunction by a thousand and one different contrivances in the flowers themselves, and the ministrations of the moth, the bee, and many other insects, and also of wind, and even of water. By such conjunction it has been abundantly proved by Darwin and others that not only is the constitution of the offspring strengthened, but also the number, and every horticulturist nowadays recognises the fact that it is to the æsthetic or other tastes of the insect tribe, the Pucks and Cupids of the floral world, so to speak, that we owe the lustre and brilliancy of our flowers, and their diversity of form and arrangement. These were the cross-fertilisers of old, as man has become the cross-fertiliser par excellence of comparatively recent times, and by his better-considered efforts has enriched the world of floral beauty with a myraid gems which Nature unaided would certainly never have fashioned.

MR. JAMES DIXON.
Winner of the Scottish Challenge Trophy for Grapes, both in 1910 and 1911.

Mr. James Dixon, head gardener to Lord Rowallan, at Rowallan, Kilmaurs, in Ayrshire, is well known throughout the South of Scotland as an especially skilful cultivator, and he has achieved great success in late years as a grower and exhibitor of grapes. Before going to Rowallan Mr. Dixon served for several years in the vineries and fruit houses at Ardgowan, the fine

Renfrewshire seat of Sir Hugh Shaw Stewart, where Mr. Thomas Lunt, recently retired, was the extremely capable and highly respected head gardener for well over fifty years. Mr. Dixon has been six years at Rowallan, and in November next it will be five years ago since he planted the two vineries there, one with Muscat of Alexandria, and one with mixed varieties of the highest class. Two years after planting the vines Mr. Dixon commenced to exhibit, and won a first and two second prizes at Glasgow. The year following he secured the leading grape prizes at Glasgow, and in 1910 he began the season by winning five firsts at Dundee, following this with two firsts at Glasgow, and finally securing the Scottish Challenge Cup at Edinburgh, all with grapes from the two vineries. In the present year Mr. Dixon commenced to show grapes at Shrewsbury, and in the great class there he was second prize winner, only missing the chief award by one point, i.e., he was half a point behind the winner. At Dundee he won the Corporation Cup for six bunches of grapes, and a first prize for four bunches; at Glasgow he secured a silver cup and first prize for eight bunches, and, as previously announced in these columns, he again won the Scottish Challenge Cup at Edinburgh, being the first to win that trophy two years in succession. Judging from this catalogue of wins it might be taken for granted that Mr. J. Dixon was a grape specialist only, but this would be quite wrong, because his skill is seen in all departments of the beautiful garden of which he has charge.

Important to Secretaries of Horticultural Societies. — The edition of the "Gardening Year Book" for 1912 is in an advanced stage of preparation, and secretaries of botanical and horticultural societies and gardeners' associations are earnestly requested to return the notices properly corrected which they have received, with as little delay as possible, so that any changes which have been made in the names or addresses of the secretaries may be duly recorded in the list of Horticultural and Botanical Societies of the United Kingdom. We shall also be glad to receive from our readers notification of any such changes as have come under their notice.

Awards to New Roses.—Occasionally writers on floricultural matters, who might be expected to appreciate the importance of an adherence to the regulations made for the guidance of exhibitors of novelties, give expression to peculiar views with regard to methods of procedure. We have a proof of this in the criticism of the National Rose Society, because a new rose possessing unquestionable merit did not receive an award on the occasion of the society's autumn exhibition, held in September. The rules made by the society for governing the awards to new roses stipulate that not fewer than six trusses shall be staged, and that, in conjunction with the blooms, "a ground plant of the variety must also be shown." The requirements of the society are very clearly stated, and the object in requiring a ground plant is, of course, to enable those responsible for making the awards to form an opinion on the growth of the variety. As we understand the case, the exhibitors of the rose staged finely-developed blooms, and with them they showed, under a misapprehension, a plant that had been grown in a pot. In consequence of their failure to comply with the rules, the committee for making the awards to new roses were, much to their regret, unable to deal with the variety, which has unquestionably merit of a high order. It has been suggested that the National Rose Society, to be truly national, must take into consideration roses from under glass as well as those grown in the open. The nationality or otherwise of the society has nothing to do with the matter. The society has framed a set of rules that exhibitors have for some years observed, and it should be obvious that they cannot be altered except in a constitutional manner. The writer we have in view recognises this after indulging in a criticism of the National Rose Society, and endeavours to show how that body may rehabilitate itself in his estimation. He advises that the society should immediately convene a special meeting, and alter the rule "relating to gold medals," and that, as soon as the rule is altered, make amends to the raiser by awarding him the gold medal. It is impossible to take a writer seriously who makes such proposals; otherwise we should ask him, Which rule is the society to alter? We know something of the constitution of the National Rose Society, but we have no knowledge of a rule relating to gold medals. To suggest that the Council should call 5,000 members together for the purpose of altering a rule that does not exist, to enable them to confer a gold medal on a rose that has not been judged officially, is perhaps the most absurd proposal that has yet been made by a writer on floricultural matters.

Alterations in the Rock Garden at Kew.—About midway through the Kew Rock Garden and on the western side considerable alterations are in progress. From the portion that is being dealt with the old tree stumps that served as supports have been removed, and a high mound has been thrown up; on this, arranged so as to form the best possible homes for rock and alpine plants, a quantity of finely weathered stone, imported from Cheddar, is being placed. To the south of this mound a very deep bay has been cut out, and one side of this will provide a fine site for plants that thrive in the full sunshine, while the other side will provide a cool spot for such things as ramondias. Mr. Irving hopes to make a stone path between the two banks of saxifragas and sedums, and carry this across the central path and round the newly-formed bay or recess, so that visitors may, in single file, be able to closely inspect the plants. Very great improvements have been effected in the reconstruction of the Rock Garden during recent years, and the plants have shown their appreciation of the new sites. A good deal of renovation remains to be done, and it is hoped that the work will be carried on each autumn until the whole is finished.

Dundee Flower Show was a financial as well as a horticultural success this year, and enabled the treasurer to show a balance of £45 8s. 6d. on the right side at the close of the year's work. The total income was £1,016 10s., and the expenditure £971 1s. 6d. The takings at the show were £639 17s. 9d. Mr. W. S. Melville has been re-elected president for the ensuing year, and Mr. W. F. Hill, of Barrack Street, continues as secretary. The show dates for 1912 are September 5, 6, and 7, to coincide with the visit of the British Asociation; £300 will be offered in prizes.

The Fragrant Sweet Pea.—The popularity of sweet peas is beyond all question, and probably no book has done more to extend the culture of these lovely and fragrant flowers than "Sweet Peas and Their Cultivation." This was the first of the books dealing with the subject, and it has now reached its fourth edition. The new issue is as interesting and instructive as the previous ones; indeed, it is more so, as further cultural details have been added, the selections of varieties for various purposes have been brought quite up to date, a new chapter deals with the extension and methods of cultivation for the cut flower markets, while numerous new illustrations constitute a special attraction. To the raiser, exhibitor, or modest amateur cultivator, the book is a mine of information. Mr. Chas. H. Curtis, the author, cultivates sweet peas largely, and his position of hon. secretary to the National Sweet Pea Society is a guarantee of the correctness of the information he offers, and an indication of his wide experience in all matters pertaining to sweet peas.

September in the North.—The past month has been the driest September experienced in the North of Scotland (writes our Aberdeen correspondent) for the past forty years, with one exception, that of 1895, when the rainfall was just the same—about two inches. This is an inch and a half below the average for the month during the period under review, the largest fall being fully six inches, which fell in September, 1872. The month, therefore, has been decidedly a dry one, but has been rather cloudy and mild. Seldom, if ever, has so little water been seen in the streams and rivulets, and in some localities the scarcity of water has been much felt, for there has been a deficiency of rain in the North this year every month except May and June. In May, indeed, the excess was so small as to be barely measurable. As a rule June is our driest month, but this year, oddly enough, it has up till this period of the year been the month in which we have had the most rain, although the weather in it was seldom at all wet, for most of the rain fell on one day, the 24th. During the last week of the month just closed the barometer was considerably above its normal height, and rather unsteady. The temperature fell steadily during this period, and the last three days of the month were cold and squally. The sunshine in some districts exceeded the average by about ten hours. The cereal crops have been secured in capital order, and the quality is excellent. The field turnips, however, are suffering for want of rain, many of the leaves turning yellow; the crop is likely to be a light one, but may make up a good deal yet should the weather prove more favourable.

Chrysanthemum Culture was the subject of an instructive lecture given by Mr. F. Phillips, of Reigate, before the members of the Croydon Gardeners' Association on the occasion of the last fortnightly meeting. There was a large attendance of members, who listened with much interest to the advice given by Mr. Phillips, on the numerous details requiring attention in the various stages through which plants grown for the production of exhibition have to pass. The cultivation of bush plants for conservatory and greenhouse decoration was also referred to at some length by Mr. Phillips, who received a hearty vote of thanks at the close of his lecture.

Liebig and Soil Fertility.—At a recent meeting at Oxford, Sir W. A. Tilden, F.R.S., gave an address on Liebig and his influence on the progress of modern chemistry. In turning to the investigations of the problems of plant life and soil fertility with which Liebig's name should ever be associated, Sir W. A. Tilden said the questions the famous chemist set himself to answer were: Whence do plants get their carbon and nitrogen, which, together with hydrogen and oxygen and water, form the material of their tissues? What is the use of the mineral substances found in the ash left on burning vegetable matter? Why are different soils adapted to different crops, and what is it that gives fertility to a soil? The state of knowledge on such subjects is indicated roughly by the summary which had been provided by the lectures of Sir Humphry Davy in 1813. During the subsequent twenty-five years very little had been done in the way of experiment, but it would be only fair to mention the name of the great French agricultural chemist Boussingault as one of the pioneers a little in advance of Liebig in the study of such questions. Briefly, the position was somewhat as follows: it was known that plants decompose the carbonic acid of the air, using the carbon and letting the oxygen go free, but it was commonly supposed that the brown or black substance in the soil, which is usually called humus, and is the result of the decay of preceding vegetable growth, was the chief source of the carbon in growing vegetables. Liebig pointed out that this was impossible, because it failed to show from what source the original plants from the decay of which humus was formed derived their carbon. Liebig was the first to study carefully the mineral constituents of plants and to recognise the importance of certain substances, especially potash and phosphates. The services which Liebig rendered to the world in connection with plant physiology and cultural methods are, however, less to be recognised in the shape of positive contributions to knowledge than in the example set and in the influence of that example in stimulating systematic investigation.

Yorkshire Railway Station Gardens.—The offer of prizes for the best-kept station gardens on the Pickering and Seamer branch of the North-Eastern Railway, had an excellent effect, and the staff at each station enters heartily into the work of making its own charge as beautiful as possible. Thorntondale, Sawdon, and Snainton Stations all receive first prizes; Pickering and Ebberston gain second prizes; while Forge Valley and Wykeham Stations each obtain third prizes. Throughout the season the stations from Pickering to Forge Valley have been a continual delight to travellers, and a great credit to every stationmaster and staff.

Canadian Fruit Crop.—We are informed by Lord Strathcona, High Commissioner for Canada, that he has received the Fruit Crop Report for the current year from the Canadian Department of Agriculture. The drought has reduced the crop, the loss being in quantity in some districts and in quality in others. In Nova Scotia and Prince Edward Island the apples are below the average in size. A feature of the reports of the Department's correspondents has been the number of allusions to the beneficial effect of clean cultivation and spraying, and another frequent comment is that the codling moth is not prevalent except in unsprayed orchards. The conclusion drawn from the reports of the correspondents is that even in years like this of insufficient rainfall and "off-years" in the apple crop, at least a medium crop can be expected in all orchards that are properly sprayed and cultivated.

International Horticultural Exhibition, 1912.—A meeting was held at the Hotel Windsor, Victoria Street, on the 10th inst., for the purpose of electing a committee for the County of Surrey to help in promoting the interests of the exhibition. Those present included: Sir Trevor Lawrence, Bart., President of the Royal Horticultural Society; Sir Albert Rollit, a member of the Board of Directors charged with the management of the exhibition; Messrs. F. A. Wellesley, E. G. Mocatta, W. A. Bilney, A. Hartman, T. Want, Leopold Salomon, J. Cheal, J. Goatley, J. Collins, M. Mills, R. B. Leach, G. Carpenter, J. Summers, W. P. Bound, A. Smith, Thomas Stevenson (hon. secretary), and others. Sir Trevor Lawrence, who presided, was subsequently elected president of the committee; he made a very interesting speech on the work which was being done in all quarters on behalf of the exhibition, and moved a resolution pledging the committee to do its utmost to forward this work.

Melons and Their Cultivation.—At the fortnightly meeting of the Reading Gardeners' Association, Mr. H. Goodger, head gardener to Mrs. Collins, Stoneham House, Tilehurst, lectured on "Melons and Their Cultivation." That so successful a cultivator of these luscious fruits gave advice of much value on the various essentials to success goes without saying; but it may be mentioned that he stated with reference to varieties that he chiefly depended upon Sutton's Ringleader, Superlative, Hero of Lockinge, and Eastnor Castle in maintaining successional supplies extending over a long period.

Exportation of Potatoes to South Africa.—The Board of Agriculture and Fisheries desire to give publicity to the new regulations issued by the Government of the Union of South Africa, whereby potatoes will be admitted from any part of the British Isles, provided that each consignment is accompanied by a declaration from the consignor stating where the potatoes were grown, and also a certificate from the Board of Agriculture and Fisheries declaring that so far as they are aware no outbreak of wart disease (black scab) of potatoes has occurred within a radius of five miles from the locality where the potatoes were grown. Applicants for the Board's certificate must forward a declaration signed by the grower of the potatoes stating where the potatoes were grown, and giving the name of the parish and county in which the farm is situated. The grower must also declare that no case of wart disease has occurred on his premises.

Weight of Apples.—Miss E. G. Badcock, of Westhay Kingston, Taunton, writes, with reference to some fine apples she has gathered: "It may interest your readers to know that from two trees of A 1 and one of Lord Derby we picked one apple weighing 20oz., another 18oz., and two or three of 1lb. These trees had no special treatment, as we had no intention of showing." Miss Badcock's note would have been still more interesting had she stated whether the larger of the fruits had been gathered from the trees of A 1—a variety, by the way, that has no place in the lists of apples to which we have access—or from the tree of Lord Derby.

Production of Potatoes in Cellars.—We have been reading in several weekly journals that a new method of raising new potatoes in cellars is attracting much attention in France at the present time. The method referred to, as proved by the context, may be receiving attention on the other side of the Channel, but it is certainly not new. It has been practised at Park Place, Henley, for a long time past, and nearly twenty years ago Mr. George Stanton, who is now the agent of the Park Place estate, described in these pages his practice in the production of supplies of "new" potatoes from tubers of the previous year placed in caves. Mr. Stanton also kindly supplied us with photographs which were reproduced and used for the purpose of illustrating his article.

FEEDING PERPETUAL CARNATIONS IN AUTUMN.

The development of all human, animal, or plant life depends, to a very large extent, upon the food supply. The long past ages have proved this fact conclusively. Therefore, when we are studying a florist's flower, such as our modern perpetual carnation, we naturally wonder to what degree the food supply has influenced its development. Certainly all can appreciate to a greater or lesser degree the necessity of correct and careful artificial feeding by studying the importance placed upon it by our best raisers and growers.

In the first place, we must realise that there is no other plant just like the perpetual carnation, which lives the strenuous life, growing without rest for the twelve months of the year, so that if it is unduly forced or fed during any one season, this is only done at the expense of the succeeding season. This is particularly so in the case of the autumn, when the plants should be kept in perfect condition to withstand the most trying period of their life, viz., the winter.

It must be evident to all that any ordinary fertiliser will not do. It is not reasonable to expect that we can have one fertiliser for all plants in the way that patent medicine vendors have one remedy for all ills. A fertiliser may be excellent for vines, but it does not follow that it will suit ericas or perpetual carnations equally well, for in the case of the carnation it is most essential that all its parts should be developed slowly and evenly.

If, for instance, you use in the autumn a very highly concentrated nitrogenous manure, which would be very excellent for many subjects, you would, in the case of perpetual carnations, make the young growths very soft, and thus weaken the stem and calyx, whilst the root action would be forced for the time being. The flowers also would not last when cut, but, worst of all, there would be a reaction, which would take place at the dullest season of the year, thus rendering your plants almost useless.

It has been a hobby of mine for years, this study of fertilisers for perpetual carnations, and, while space will not allow me to go closely into the matter, I can say I have been perfectly convinced that the only suitable fertilisers for perpetual carnations are mainly composed of organic matter, and for that reason I have for years compounded my own carnation food.

The advantage of an inorganic fertiliser is that all the food is not immediately available to the plant, but is given off gradually while the slow decomposing process is going on. This has a wonderful invigorating action upon the roots, and hence upon the whole plant if the parts of the fertiliser are evenly balanced. In the case of the perpetual carnation nitrogen should not predominate over the other essential parts.

A good sample of steamed bone flour is the best source of phosphates, and is one of the best manures for autumn use. We prefer hardwood ashes as a source of potash, while dried sheep-manure or blood and soot are excellent sources of nitrogen. Of course, you could obtain these manurial parts from cheaper sources, but I am a strong believer in the best for carnations.

I am not an advocate of liquid natural or yard manures, simply because none of us really know their strength from day to day. They are also, as a rule, too rich in nitrogen for carnations. In fact, I greatly prefer top-dressing, particularly in the autumn.

The question will arise in the minds of some: Do I favour autumn feeding for perpetual carnations? My reply is: Yes; if plants are well established, and require additional food, and providing one has the right sort, in small quantities. For if you do not feed your plants they become hard and checked.

In short, perpetual carnations can be fed during any season of the year, providing small quantities are given, but the food must be a veritable diet, and not merely a stimulant. Montagu C. Allwood.

NATIONAL SWEET PEA SOCIETY.

Classification of Sweet Peas.

The Floral Committee presents the following as an up-to-date selection of varieties. The varieties in each colour class are placed in order of merit:

* Indicates a grandiflora variety; all others are waved.

Bicolor.
Mrs. Cuthbertson
Arthur Unwin
Mrs. Andrew Ireland
Colleen

Blue.
Flora Norton Spencer
Mrs. G. Charles
*Lord Nelson

Blush.
Mrs. Hardcastle Sykes
Princess Victoria

Carmine.
John Ingman

Cerise.
Cherry Ripe
Chrissie Unwin
*Coccinea

Cream, Buff, and Ivory.
Clara Curtis
Paradise Ivory
Isobel Malcolm

Cream-Pink (Pale).
Mrs. Routzahu
Mrs. Hugh Dickson
Gladys Burt

Cream-Pink (Deep).
Doris Usher
Mrs. R. Hallam
Constance Oliver

Crimson.
Sunproof Crimson
Maud Holmes
King Edward Spencer

Fancy.
Afterglow
Charles Foster
Prince George

Lavender.
Masterpiece
Asta Ohn
Florence Nightingale

Lilac or Pale Mauve
Mauve Queen
Winsome
Mrs. R. H. Carrad

Magenta.
Menie Christie

Marbled & Watered
May Campbell
*Helen Pierce

Maroon.
Nubian
Tom Bolton
Black Knight Spencer

Maroon-Purple.
Arthur Green
Mrs. J. M. Gerhold

Maroon-Red.
Red Chief.

Mauve.
Queen of Norway
Tennant Spencer
Wenvoe Castle
Helio-Paradise.

Orange-Pink.
Edrom Beauty
Helen Grosvenor
Helen Lewis

Orange-Scarlet.
Thomas Stevenson
Dazzler
Edna Unwin

Picotee Edged.
(Cream Ground.)
Mrs. C. W. Breadmore
Evelyn Hemus

Picotee Edged.
(White Ground.)
Elsie Herbert
Marchioness of Tweeddale
Mrs. Townsend

Pink.
Elfrida Pearson
Hercules
Countess Spencer

Rose.
Rosabelle
Marie Corelli
Marjorie Willis

Salmon Shades.
Stirling Stent
Barbara
Melba
Earl Spencer

Scarlet.
Red Star
Scarlet Emperor
George Stark

Striped and Flaked.
(Purple and Blue.)
Loyalty
Suffragette

Striped and Flaked.
(Chocolate on Grey Ground.)
W. R. Beaver
Senator Spencer

Striped and Flaked.
(Red and Rose.)
Mrs. W. J. Unwin
America Spencer
Aurora Spencer

White.
Etta Dyke
Nora Unwin
*Dorothy Eckford

Too-much-alike Varieties.

The following varieties have been bracketed as too-much-alike. "Not more than one of the bracketed varieties shall be shown on the same competitive stand at any exhibition of the National Sweet Pea Society." The names are placed in alphabetical order. For Order of Merit see "Classification of Sweet Peas":

Blue.
Anglian Blue
Flora Norton Spencer
Kathleen McGowan
Shawondasee
Zephyr

Blush.
Bobby K.
Countess of Northbrook
Florence Morse Spencer
Lady Evelyn Eyre
Mrs. Hardcastle Sykes
Princess Victoria

Blush Spencer
Lady Althorp
Mrs. T. G. Baker
Paradise Regained
Sankey Spencer

Carmine.
E. J. Castle
George Herbert
John Ingman
Mrs. W. King
Paradise Carmine
Spencer Carmine

Cream, Buff, & Ivory
(Grandiflora.)
Harold
James Grieve
Mrs. Collier
Mrs. A. Malcolm
Yellow Hammer

(Waved.)
Clara Curtis
Giant Cream Waved
Mrs. Miller
Paradise Cream
Primrose Paradise
Primrose Spencer
Primrose Waved
Princess Juliana
Waved Cream (Malcolm's)

Paradise Beauty
Paradise Ivory
Queenie
Sea Foam
Lady Knox.

Cream-Pink.
A. B. Bantock
Earl of Plymouth
Holdfast Belle
Juliet
Mrs. Alec Ware
Mrs. Henry Bell
Mrs. Hugh Dickson
Mrs. Routzahn
Mrs. S. S. Champion
Queen (Sutton's)
Queen Mary
Romani Rauni
Seashell
W. T. Hutchins

Cream-Pink (deep).
Anglian Pink
Doris Usher
Lancashire
Minnie Furnell
Miriam Beaver
Mrs. Gibbs Box
Mrs. R. Hallam
Syeira Lee

Constance Oliver
Nell Gwynne

Crimson.
Dodwell F. Browne
G. C. Waud

Marie Louise Pears for Stewing.—I can quite understand many readers objecting to the use of this grand pear for stewing purposes. But where there are many specimens of the variety, and special stewing pears are required, there is not a single variety that excels it. A lady once remarked to me, "Why always use the poorer and more gritty pears for stewing, when Marie Louise makes the best stewing pear there is." I confess I had never tried the variety in this way, but did so at once. The lady was quite right; I, personally, never tasted stewed pears to equal them. Probably many readers have had experience of the use of good dessert varieties for stewing?—G. B.

Gesnera Orange King.—Two or three times during the present autumn good examples of this pretty gesnera have been shown at the meetings of the Royal Horticultural Society. The foliage is of that pretty reddish tint, with a velvety lustre. which prevails to a greater or lesser extent in many of the garden varieties of gesnera. The flowers, borne in a large pyramidal, terminal panicle, are, as indicated by the name. of a bright orange colour. This gesnera is well worthy of a note, not only for its own intrinsic merit, but for directing attention to the great value of many gesneriaceous plants for the embellishment of our glass structures during the autumn months.—W. T.

Retarded Bulbs of Lilium longiflorum giganteum.—Quite recently I saw two large batches of Lilium longiflorum giganteum and L. longiflorum respectively. Both were grown from retarded bulbs, but the latter were poor indeed compared with the former. Every bulb of giganteum had done well, and produced a strong spike of lovely large blooms. but only a few bulbs of longiflorum had grown fairly well, and were bearing one and two blooms each. The cultivator assured me that it was not an isolated case, and that L. longiflorum. with him, had always failed, whereas the retarded bulbs of L. l. giganteum had always succeeded under similar treatment.—G. B.

EXHIBITING ROSES IN BASKETS.

Within the past two or three years the National Rose Society has introduced the method of exhibiting roses in plain round baskets, and the success achieved in so doing has far surpassed expectations. So far this method of showing roses has been limited to perpetual-flowering decorative roses, with a view to bringing into greater predominance varieties that are more remarkable for continuity of flowering and effectiveness than for the size and form of individual blooms. The importance of such roses being constantly kept before rose lovers who grow them exclusively for beautifying their gardens is so great that we do not suggest there should be an alteration in the classes of roses that may be shown in this manner at the exhibitions of the National Rose Society; but there can be no doubt that the exhibition varieties would present an attractive appearnce arranged in round baskets. We therefore suggest that classes be provided for baskets of roses at local shows without reference to any particular class or section. This method of staging appears to be especially adapted to the requirements of large numbers of exhibitors of roses at such shows, and the provision of classes for them in the schedules of societies in provincial centres would, we have good reason to believe, prove, in the majority of cases, a distinct advantage. The baskets herewith illustrated were shown at the National Rose Society's Metropolitan exhibition in July last, in the nurserymen's class for five baskets, and both formed part of winning collections. Sea Bird, shown by Mr. Hugh Dickson, of Belfast, is a charming pure white hybrid tea, and the Lyon Rose, exhibited by Messrs. Spooner and Son, of Woking, was represented in such excellent condition as to show the bright and distinctive colouring characteristic of the variety at its best.

G.M.1848.
G.M.1848.

AN ATTRACTIVE BASKET OF THE LYON ROSE.
Exhibited by Messrs. W. Spooner and Son at the N.R.S. Metropolitan Show in July last. The colour bright orange-red.

ROSES FOR FORCING.

There is no flower grown in this country that is such a universal favourite as the rose, for not only is its delightful fragrance appreciated at all seasons of the year, but more especially so during the winter and early spring months, when flowers are scarce. The blooms are doubly valuable when well grown, and on stems of sufficient length and strength to carry them upright. To grow roses well in pots needs more than ordinary attention, for the plants are gross feeders; therefore, unless well looked after, will soon become a prey to all sorts of diseases, for their roots being so restricted cannot go in search of food. It is useless to attempt forcing roses unless the plants are well established, and when grown in pots, either for conservatory decorations or for providing cut blooms, they should have been potted at least one year previous to forcing, and if planted out they should have a season in which to recover themselves after being shifted.

Roses in Pots.

Those who are desirous of having early blooms, and have not hitherto made preparations would do well to purchase plants already established in pots, but in most private gardens of any pretensions there is usually a batch grown for this purpose. The present is a good time to examine them, repot, prune, and so prepare them in readiness for introduction to gentle heat. The soil used should be a good, sound, rich, turfy loam, to which may be added sufficient half-inch bones, broken charcoal, and lime rubble to make the whole porous, so that water may pass through freely. When potting, remove only the loose old soil, so as not to injure the roots, and give pots large enough to provide for sufficient food to carry the plants through the season, for, as before remarked, roses are gross feeders.

Pot rather firmly, especially if the soil is of a light nature. When potted stand them on a bed of ashes until they are placed in the forcing house. Those intended to bloom early should be pruned at once, while those not required to be housed until the new year may be left unpruned awhile. I have always found it a bad plan to hurry the plants much, for when forced excessively the petals are soft and the flowers of little use, either for cutting or conservatory decoration. Make up a gentle hotbed in the forcing-house, and at this season of the year there are usually ample leaves, which, if collected when dry, will retain heat for a considerable time. The temperature of the hotbed should not exceed 70 degrees at the base of the pots; if higher do not plunge the pots, but stand them on the surface until the temperature has somewhat declined. The beds should be examined daily in order to ascertain if the temperature is likely to rise too high, for as the roots of roses are tender, they will easily scald. When the temperature of the bed is safe, the pots may be plunged therein up to their rims.

Pruning is a simple operation, but as all cannot be pruned alike it requires a great deal of practice to know how each individual variety should be pruned, but it may be safe to say the strong-growing kinds ought not to be cut back so hard as the weakly ones. Remove all growths that are too thin to produce blooms, and encourage those that are well ripened, having good plump buds. It is quite impossible to lay down any hard and fast rules for pruning, but if a full crop of blooms is to be produced do not prune too heavily.

When the plants are first put into the forcing house, do not excite growth too quickly: a little air should be admitted night and day, whenever the weather is favourable, but should cold winds prevail great care must be exercised in this respect, as the young foliage, being very tender, is apt to get mildewed should there be cold draughts. Syringe in the afternoon to keep the foliage clean, and should green fly make its appearance fumigate at once, for this pest should by no means be allowed to increase. Mildew is a great trouble among forced roses, and should never be allowed to spread. On its first appearance syringe the plants with liver of sulphur in a very diluted form, half an ounce to a gallon of soft water.

As growth develops it will soon be seen which shoots are carrying bloom buds, and as soon as these buds are large enough, thin them out to one on each stem, so that they may become fully developed, for unless the flowers are of fair size they will be of but little use for decorative purposes. The best kinds of roses for forcing are those of distinct colour, as these may be used to the best advantage either for home decorations, bouquets, or the like. Choose those that are free bloomers and of good substance rather than those of exquisite form for exhibition. Some of the finest roses seen on the exhibition stands are of little use for general purposes. It is better to grow a few plants of each of the finest roses rather than a number of varieties, one or two plants only of each. For example, it is far better to grow a dozen plants of Richmond than half a dozen each of that and Liberty, as the colour is very similar, but the former is by far the best grower, and produces finer flowers. Again, for a white variety, there is no necessity to grow more than two or three sorts. What could be better than the White Maman Cochet? It is a grand rose, of good form, and an excellent grower. One may gather from this and come again another day. The old Niphetos, though it has been grown for far more than half a century, still holds its own for forcing, as it is so beautiful in the bud. Of pinks and salmon-pinks there are many, such as Caroline Testout, Dorothy, Mamam Cochet, Mdme. Lambard, and the like; they are all good and continuous bloomers. Those who prefer a flesh-coloured rose could not do better than grow Catherine Mermet, Bridesmaid, or Georges Nabonnand. As there is such a variety of shades in roses, and individuals have their particular fancies as to colour, it is necessary in some instances to grow a special variety.

But my object is to point the way to produce a quantity of bloom rather than to recommend certain varieties. At one time there was thought to be no red rose like General Jacqueminot for forcing, but others have now taken its place. As a white variety Frau Karl Druschki is perfect in form, and though it grows well in the open and blooms most profusely, it has not done so well when forced, being subject to mildew. The best kinds for producing a wealth of bloom are Teas and Hybrid Teas, and there is sufficient variety in these to please the most fastidious, both in colouring and shape. They are not so subject to mildew as the H.P.'s, and the foliage is far more pleasing, but most of them are strong growers, and therefore need feeding when in active growth, especially when the pots become filled with roots. Plunged in a bed of leaves the soil does not soon get dry, and as there is a gentle warmth therein the roots will soon find their way through the bottom of the pots and feed. It is astonishing how fast the plants will grow, and what a wealth of bloom they will produce if well attended to in the way of watering and keeping them clean, but if neglected they soon become a prey to red spider and other pests.

What is a good manure? Where it can be procured, that from the farmyard is undoubtedly the best, but as this cannot always be had, dried blood or guano may be used as substitutes. These are most powerful fertilisers, and should be used with caution: it is better to err on the side of giving too little than too much. Sulphate of ammonia is also a powerful stimulant, and if a little of this be dissolved in the water it is astonishing the colour it puts into the foliage: but this must not be over done. There are many concentrated manures sent out by different firms that are also highly beneficial, but care is needed in using them. Soot water is also very useful.

H. C. Prinsep.

PREPARATION OF ROSE BEDS.

It was at one time generally supposed that the only soil in which it was possible to grow roses to perfection was one of a stiff clayey nature. That idea has been exploded, for it has been proved by the magnificent blooms we see at the various summer and autumn shows that such soil is not essential to success. These flowers have come from different parts of the country, and have been produced by plants growing in practically every kind of soil except sand. I am well aware that a fairly good soil has had something to do with their production, as also have climatic conditions, but really the main factor has been the provision of properly prepared beds for the plants. The proper preparation of the beds in the first place is of far more importance than anything else, and no amount of manure or care expended on the plants afterwards can remedy the fault of a badly made bed.

To state the case briefly, a properly prepared rose bed is one so made as to ensure efficient drainage, a free root run that is warm and enriched, and with soil so treated as to conserve the moisture in such manner as to provide a supply during drought, though at the same time not interfering with the escape of superfluous water. I have long since come to the conclusion that one need not trouble much about the aspect when making rose beds. Provided they are not overshadowed by large trees, and are sheltered a little from the N. and N.E. winds, the roses planted in them are sure to thrive. The first thing we have to look to is drainage. If the ground is on a slope, it will only be necessary to cut a trench about 3ft. deep across the lower end, and lay in a row of 3in. drain pipes, covering them with old brick rubbish, coke, or clinkers. If it is not possible to carry the outlet into a ditch, a hole must be dug at the lower end to take the discharge. Where the ground is fairly level, and an outlet can be arranged, a row of pipes down the centre of the bed will be sufficient, but where no outlet can be provided the only way out of the difficulty is to raise the bed twelve to eighteen inches above the ground level.

The drainage having had provision made for it, the next step is the preparation of the soil by trenching to the depth of at least thirty inches, the object being to improve its moisture-retaining properties. If the subsoil is clay, begin the operation by digging out a section of the top spit three feet wide and fifteen inches deep, and wheel it away to the end of the piece of ground that is being worked. The lower spit should then be thoroughly broken up to the depth of another fifteen inches, and a layer, six inches in thickness, of well-decayed straw or peat moss stable manure incorporated with it. It is preferable to use stable manure instead of that from the farmyard on a clay soil, which is naturally wet and cold, as it enables us to enrich and lighten it without souring. A little basic slag, 3oz. to the square yard, should be added. We then proceed with the next breadth, and after we have placed about six inches of soil on top of the first trench, a thin layer more of manure may be added, together with any road-sweepings—not from tarred roads—decayed leaves, and burnt earth, so as to provide a free, warm root run that will induce the roots to spread out instead of running down. As the bed is being built up to the required height, add a third of a pint of $\frac{1}{4}$in. bones to the square yard. The first breadth being completed, the process may be repeated until the bed is of the required size.

Where the subsoil is gravel or chalk, and the ground naturally drained, the object will be to make the soil more retentive of moisture, and to enable us to do that we must use farmyard manure instead of that from the stable. If there is not sufficient depth of soil, do not be afraid to break up the chalk, only take care to work in planty of manure with it, and, if possible, use also some good stiff, clayey loam. For the middle layer, instead of using road sand, obtain some top spit from an old pasture, and work in with it decayed manure. Then bring the bed up to the required height with the natural soil.

Where it is intended to plant roses singly on lawns, the soil—if clay—should be removed to the depth of three or four feet, and a layer, nine or ten inches in thickness, of clinkers or brick rubbish put in before the bed is made up.

On no account let any manure come into contact with the top soil to a depth of at least six inches. Keep it as sweet as you can, so that when the trees are planted, the roots will be able to travel to the warm middle layer of the bed, and as they develop draw upon the nourishment therein provided.

APPLE COX'S ORANGE PIPPIN.

Some cultivators are not very successful with this fine apple, and they tell others that they will also be disappointed in the variety. I have personally heard far more praise than condemnation of Cox's Orange Pippin, and as far as my own experience goes, have found it a free-fruiting variety, free in growth and free from canker.

I think that some growers fail through allowing the roots to get away so much into loose, rich soil. When this happens, the shoots made are very strong and do not well and satisfactorily ripen in an ordinary season; then there is loss of time and space, and some labour is entailed in the work of root-pruning.

Some years ago I planted a few dozen of apple trees in a row on the north side of four vegetable plots, so they had a good, sunny position. All did well, including Cox's Orange Pippin. The soil was good and the trees made satisfactory growth; indeed, the variety named would have grown too grossly only for the fact that the roots were specially cut back when the digging of the vegetable ground was done. Other trees, grown in very firm soil and in a fairly restricted area, also did well.

BEES, LTD., 175E, LIVERPOOL.

A FEW OF THE NEWER ROSES.

After such an abnormal season through which we have just passed it is exceedingly difficult, not to say unfair, to offer any definite opinion on the qualities of the newer roses. We ought rather to "Wait and see." But one feels that when a particular variety has been more or less satisfactory throughout the year 1911, it cannot be an inferior one. Added to this there is another difficulty, one cannot deal with even half the number of new roses that during the last year or two have been put on the market. To do so is quite beyond my power, and would occupy more space in these columns than is at my disposal. Besides, what is the good of it? One has grown but few of them, and can only rely on the descriptions given in the trade catalogues. No, the task is too onerous. Let us, therefore, confine our attention to some few of the vast number, some that have been tested in our garden and done well during the past season. The first three in the following list come from Alex. Dickson and Sons, of Newtownards.

Dr. O'Donel Browne (H.T., 1908).—Carmine-rose, large massive flowers, full, well formed, very sweetly scented. Too strong for decorative purposes, but excellent for exhibition. Blooming continuously early and late.

George C. Waud (H.T., 1908).—An attractive colour, deep salmon-pink, with orange shading. Free flowering, spreading habit, suitable for bedding.

Countess of Ilchester (H.T., 1909).—Carmine-pink, spreading habit, very free flowering, good early and late. Good for bedding.

Of the firm of Hugh Dickson, Belfast, three good roses may be mentioned:

Leslie Holland (H.T., 1911).—A beautiful rose, deep scarlet, perfect in form, excellent for exhibition, and probably equally as good for bedding. Very sweetly scented. It is, if anything, too free flowering, and for all purposes must be well thinned. This is one of the best roses of the year.

Countess of Shaftesbury (H.T., 1911).—Here we have another free-flowering, sweet-scented rose. One would say it will take a leading position in the garden. It is perfect in shape; colour, carmine, shaded pink, distinct.

Cynthia Forde (H.T., 1909).—Colour, light rosy-pink. A capital bedding rose, and when more known will be popular in the garden. What General McArthur is amongst reds that will Cynthia Forde be amongst pinks.

S. McGredy and Son, of Portadown, have given us two valuable roses:

Mrs. Arthur Coxhead (H.T., 1910).—This is the sweetest scented rose sent out since the decline in the hybrid perpetuals, a true damask perfume. The flowers are large, handsome, and stand erect. The suspicion of purple in the shading of crimson is a defect. Nevertheless it is a grand rose both for exhibition and the garden; so free flowering, so impervious to wet, and giving as good flowers, if not better, now in mid-October, as in the height of the season. Despite its colour, I think one may confidently say it is the best new rose of the year.

Mrs. Alfred Tate (H.T., 1909).—A very good distinct decorative rose. Coppery-red, shaded fawn, elegant long pointed buds, semi-single, very free, continuous in flowering, good in autumn. One of the best.

From Messrs. Benjamin R. Cant comes:

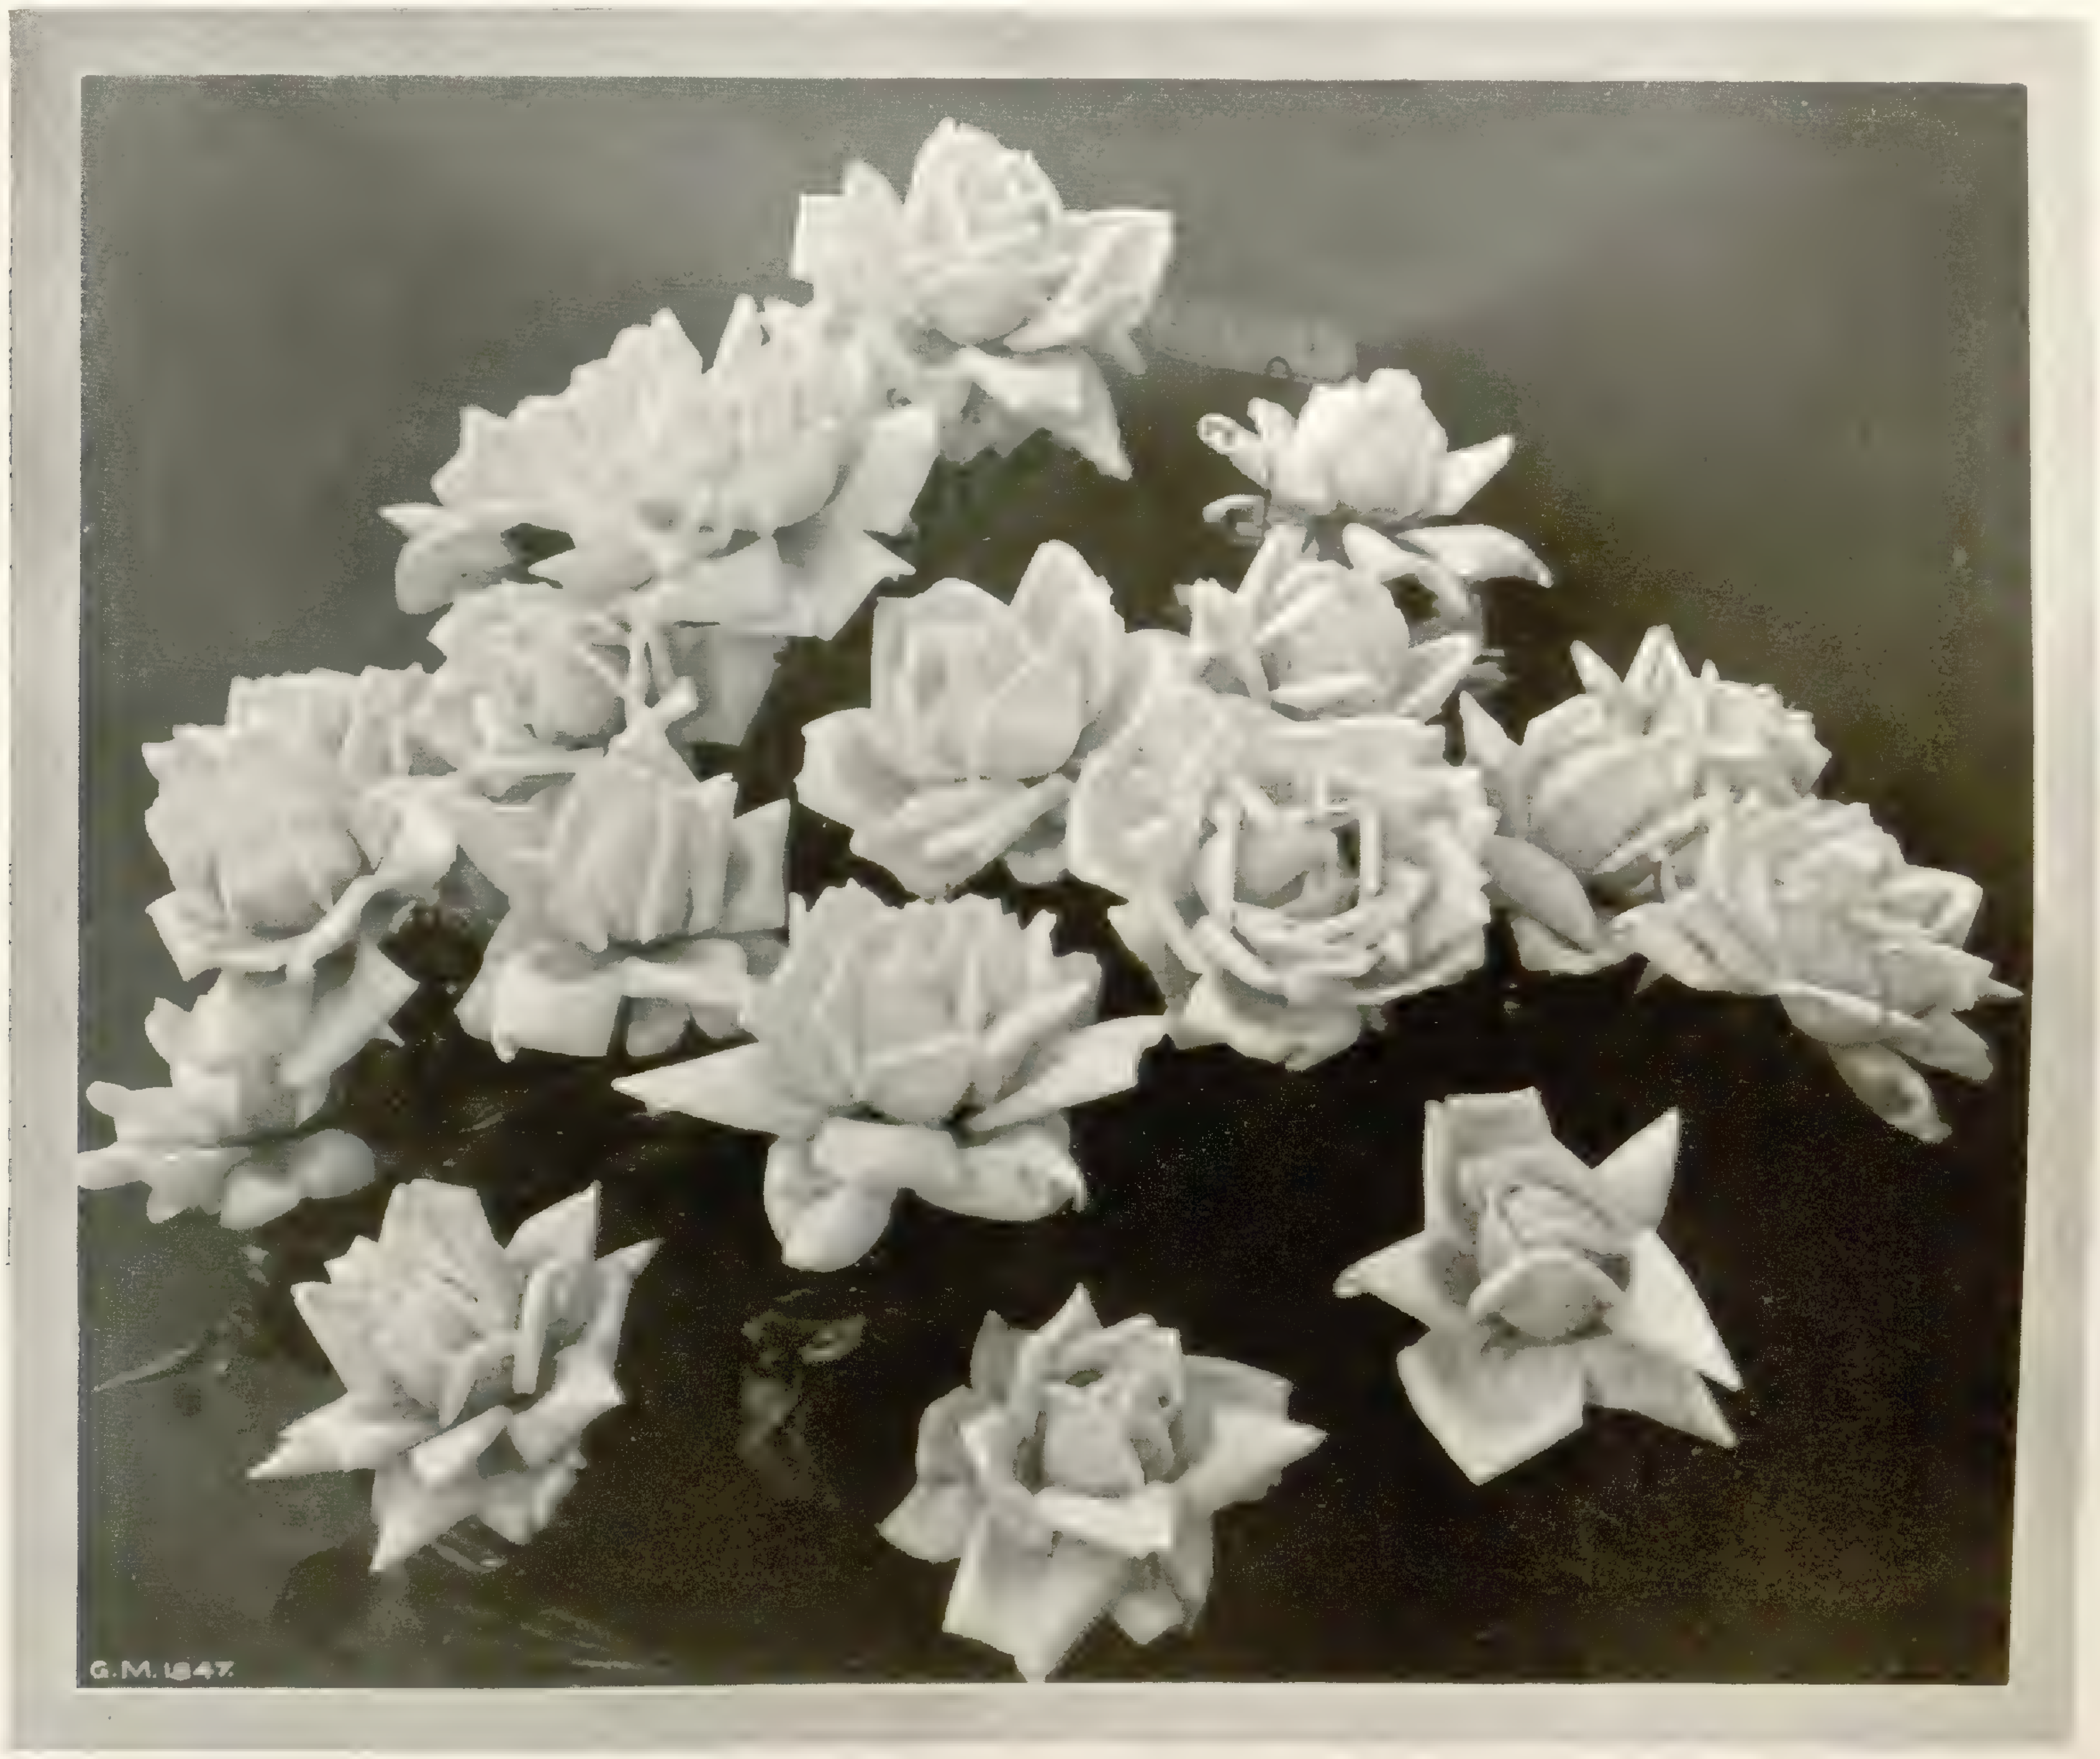
Claudius (H.T., 1910).—Colour, carmine-rose, globular pointed, very free flowering, blooming until late in autumn, sweet scented, suitable for exhibition and garden.

Of the Continental raisers the firm of Pernet-Ducher takes a leading position, and there are many new roses coming from this grower which will be attractive. Of such varieties as Viscountess Enfield, Beaute de Lyon, and Lieut. Chaure it is as yet too early to speak, but two deserve special notice here:

Rayon d'Or (Pernetiana, 1910).—This is too well known to need description. It is the deepest yellow rose we have, and all other yellows pale before it. Freedom in flowering will make it a desirable bedding variety, provided its constitution is good.

Chateau de Clos Vougeot (H.T., 1909).—Colour, deep scarlet. Probably the darkest hybrid tea we have. Growth branching. Very free flowering, sweet scented. In character more of a China than a hybrid tea. Can be highly recommended for massing.

Joseph H. Pemberton.



A BEAUTIFUL BASKET OF ROSE SEABIRD.

Exhibited by Mr. Hugh Dickson at the N.R.S. Metropolitan Show in July last. This variety belongs to the hybrid tea section, and has white flowers.

THE TWELVE BEST WICHURAIANA ROSES.

Everybody knows the story of the resourceful undergraduate who, on being asked to give the names of the major and minor prophets, answered: "Rather than draw invidious distinctions between these holy men I give a list of the Kings of Israel and Judah."

My apology for telling so old a story is that, having undertaken to write of the twelve best Wichuraiana roses, I find the task of selection very difficult, and when I see that in the "Rose Annual" for 1909 Dr. Williams writes of there being already "close on a hundred beautiful hybrids of Rosa Wichuraiana," I feel tempted to take refuge, to some extent, in the undergraduate's subterfuge, and "rather than draw invidious distinctions" to give a descriptive list of these roses, nearly all of which have some merit, leaving my readers to choose for themselves.

History does not tell us in what light the examiners treated our undergraduate's answer. I doubt whether he would come off with flying colours, and I feel quite sure my somewhat feeble imitation of his methods would not be appreciated.

In making the following selection of twelve Wichuraianas I have tried to choose those varieties which are really distinct (for instance, Lady Gay is omitted as being too much like Dorothy Perkins to be included with it in a small selection), to represent all the different colours, the early and late flowering sorts, and also to recommend in so small a collection only those with really excellent foliage.

To my mind the foliage of a climbing rose is quite as important as its flowers—perhaps more so—for the foliage drapes our pillars, arches, and pergolas for at least nine months of the year, while the blooming period of any one variety is seldom more than six or eight weeks. In their beautiful glossy foliage the best Wichuraianas excel all other varieties of hardy climbing roses; in some of them, such as Jersey Beauty and Edmond Proust, it is evergreen, and in most it is mildew-proof. The pink varieties are perhaps the most numerous, and certainly the most showy. I have chosen from among them Dorothy Perkins, with her pale sport Lady Godiva, the graceful Débutante, and the fragrant Gerbe Rose.

Dorothy Perkins is as well known throughout England as the old Glory of our younger days. Its wonderful bunches of brilliant pink flowers light up our cottage gardens, and add to the beauty of our villages in a way Reynolds Hole's old favourite could not do. It was one of the first of the hybrids introduced by Messrs. Jackson and Perkins in 1901, and is said to be a cross between Wichuraiana type and Madame Gabriel Luizet. It usually begins to flower about mid-July, though this year its first blossoms appeared in our garden on June 26; in an average summer it lasts well till the end of August, and often puts out some autumn flowers in October. It is best grown on a pergola or arch, rather than as a pillar rose, its branches hanging in festoons make a very beautiful rosy canopy, and its rampant growth has to be too severely restricted as a pillar. It is very effective trained fan-wise on a fence, and makes a splendid weeping standard. In fact, it has so many good qualities that if we were restricted to growing one Wichuraiana it would have to be "Dorothy." The catalogues describe it as sweet scented, but I can detect very little fragrance. Minnehaha has been omitted from the chosen twelve on account of its likeness to Dorothy Perkins, but the bunches of bloom are less closely packed, and have a more diaphanous and elegant effect. The colour is not so uniform—there are tints of a paler pink—and some, for this reason, might prefer it to the better-known Dorothy Perkins.

Lady Godiva.—This I first saw flowering in Messrs. Paul and Son's nurseries at Cheshunt, in October, 1909 (it had been introduced by them in 1907). Its delicate creamy-pink blossoms attracted me at once, and I ordered a plant for a new rose garden, where it has rapidly covered a tall pillar, and has been much admired. The flowers keep unusually well when cut. At the end of July, in this torrid summer, when I had almost given up cutting H.T.'s and teas for the house, so fleeting was their existence, I arranged a table with little bowls of Lady Godiva. At the end of four days I wanted a change, but the flowers were perfectly fresh, and lived for three days more in my drawing room.

Debutante, brought out by Walsh in 1905, comes into flower earlier than "Dorothy" and her sports, and does not last so long. The petals fall quickly when the flowers are fully expanded. It has a very graceful habit, throwing out from the main stems slender arching sprays of light green leaves, with ruddy-tipped stems, and light hanging cascades of pale pink sweetly scented flowers.

Gerbe Rose, introduced by Messrs. Fangue and Sons, in 1904, is said to be the offspring of R. Wichuraiana crossed with Baroness Rothschild. In the smooth thick stems, so unlike most of the sinuous hybrid Wichuraianas, we may trace its descent from Baroness Rothschild, but fortunately it takes after its other parent in the matter of fragrance, and is perhaps the sweetest scented of any in this class. The soft pink flowers appear early—the second week in June—and are almost exactly the shade of the old Bourbon Hermosa. They are large for a Wichuraiana, semi-double, and come singly. This variety has no great burst of bloom, nor is it rampant in growth, so would not be at all suitable for covering a pergola or arch; but its lovely wreath-like sprays of large light green leaves look well on a low pillar, or when grown as a bush, and its fragrant flowers appear at intervals all through the summer.

White Dorothy.—As far as I know there is only one good white Wichuraiana, and that is White Dorothy, a sport from Dorothy Perkins, which it resembles in every particular except the colour of its flowers. These are pure white, save that as the flowers age the anthers darken, giving a blackish appearance to the centre of the blooms; occasionally its parentage asserts itself, and some pink, or pink and white flowers make their appearance.

Of yellows there are enough and to spare. Three of the best are Jersey Beauty, Alberic Barbier, and Chain of Gold.

Jersey Beauty.—One of Mr. Manda's early introductions, was raised from a cross between Wichuraiana and Perle des Jardins. It is a rampant grower, with glossy evergreen foliage and large single pale yellow flowers. The blossoms appear about the middle of June, and keep up a succession for six weeks or so. It is not at all fastidious as to position, and will grow and flower well even near the shade of large trees.

Alberic Barbier (Barbier, 1900) is the result of a cross between Wichuraiana and Shirley Hibberd. It is the most continuous in flowering of any of the Wichuraianas I know, beginning the first week in June and blooming more or less right on to the end of August. Its soft pale yellow buds, opening almost white—some singly or in sprays of three or four blosoms—and are very beautiful. They last well in water, and have a decided tea fragrance. I have chosen this rose in preference to Gardenia, also a lovely variety with orange-yellow buds, splashed outside with crimson (in the way of Gustave Regis), on account of its more perpetual habit and the superiority of its foliage, which is very glossy.

Chain of Gold (Messrs. Paul and Son, 1910) comes from Jersey Beauty and Instituteur Sirdey. Its name alone should commend it, and, as far as I have been able to judge, it is worthy of its attractive title. The golden-yellow buds are a fine colour, and do not pale so quickly as most of the yellows, while the shining foliage, deepening to bronze, is very dense, and almost evergreen.

Among the Wichuraianas, as among the teas and hybrid teas, there are some shades very difficult to classify. In this connection I notice a good deal of indignation has been aroused by the Lyon Rose having been awarded prizes for the "best yellow rose."

Francois Juranville (Barbier, 1906) and Paul Transon (Barbier, 1902) are perhaps the most generally useful among these salmon-pink and copper shades. Paul Transon is a very strong grower even for its class. Its coppery-pink blooms appear about mid June, and last several weeks; it also flowers slightly in the autumn, and is decidedly fragrant.

Francois Juranville, with rather large loose flowers, is one of the most beautiful of this family. Its dark green foliage, changing to bronze, is very handsome, and harmonises most happily with the coppery-rose blossoms. At the Canterbury Rose Show this June I saw a lovely bowl arranged with Francois Juranville. It was as pleasing to the sight and smell as anything in the show. The fragrance to me is the exceedingly pleasant one of ripe apples. This is a midseason variety, and usually has a few autumn flowers.

Without entering into the controversy as to whether Hiawatha and Excelsa are true Wichuraianas, I have chosen them as the best crimsons because for garden purposes they should undoubtedly be classed with this family.

Hiawatha (Mr. M. H. Walsh, 1905) is almost as popular as Dorothy Perkins. The light crimson single flowers, with a white centre, are borne in large trusses, and make a brilliant effect in the garden, lasting in perfection for many weeks. Near London its usual time for flowering is late—the middle of July—so I was surprised, when stopping at Grasmere early in June, to see several weeping standards in full flower, while only last week—on October 2—I saw a plant of Hiawatha in flower on a bank in a Gloucestershire garden. The only fault of this variety is that it entirely lacks fragrance.

Excelsa (Mr. M. H. Walsh, 1909), with light crimson double flowers, is, in respect of perfume, more fortunate. I believe it is also a strong grower and free bloomer, but it has only been in my garden a few months, and, consequently, has not yet shown of what it is capable in the way of growth.

In conclusion I would advise all rose growers in search of hardy and quick-growing climbers, whether for pillar, arch, or pergola, to look for them among this comparatively new race of hybrid Wichuraianas. They surpass all other roses for weeping standards or for growing over banks and other rough places. There are now so many beautiful varieties my difficulty has been in limiting myself; it would be quite easy to select another dozen nearly as good.

WHITE LADY.

NEW PLANTS, ETC.

◆

CYPRIPEDIUM ROYAL GEORGE.

A marvellously fine hybrid that has the merits of large size, fine colouring, and good form. The parents are C. Harrisianum superbum Undertell variety, and C. Minos Youngi. The rounded and bold dorsal sepal has a breadth of about three inches, and is white tinted with rose, and beautifully veined all over the centre and base with rich dark rosy purple. The broad petals curve forward a little, and both in form and their greenish-yellow and purple-brown shading they remind one of the hybrid C. Beckmani. The wide lip is shining purplish-brown. The stock of this splendid new orchid has passed to Mr. Francis Wellesley's collection at Westfield, Woking. F.C.C., R.H.S., October 10. Messrs. Armstrong and Brown, Tunbridge Wells.

CYPRIPEDIUM LUCIFER.

A particularly shapely and attractive hybrid derived from C. Niobe Westonbirt variety crossed with C. Euryades. The rounded dorsal sepal is white with a medium dark band of rose-purple, and stains and veins of the same colour, but of lighter shade, over the centre and base. The broad petals are purplish-brown over greenish-yellow, and the lip is rich red-brown. F.C.C., R.H.S., October 10. Lieut.-Colonel Sir G. Holford (grower Mr. H. Alexander), Westonbirt, Gloucester.

ODONTIODA EUTERPE.

A new and showy hybrid between Cochlioda Noetzliana and Odontoglossum Uro-Skinneri. The flowers are orange-scarlet save for some rosy colouring on the lip. F.C.C., R.H.S., October 10. Messrs. Charlesworth and Co., Haywards Heath.

NYMPHÆA LISTERI.

A fine new seedling water lily, belonging to the stellata group, and therefore not hardy in this country. It has large, handsome flowers of a deep blue shade, with golden centre. The flowers are carried well above the water. A.M., R.H.S., September 26. Earl of Warwick (gardener, Mr. H. Lister), Easton Lodge, Dunmow.

DAHLIA BRENTWOOD YELLOW.

This splendid large-flowered decorative dahlia has been figured in these columns. It is a big, bold, and shapely golden-yellow variety of undoubted merit, as it carries its flowers clear of the foliage on stiff stout stems. It is free-flowering and grows 3ft. or 3ft. 6in. high. A.M., R.H.S., October 10. Mr. J. T. West, Brentwood.

CHRYSANTHEMUMS.

Cranford Yellow.—A large-flowering early variety of fine form and substance, excellent for market use. A.M., R.H.S., October 11. Mr. W. Roots, Holly Cot, Cranford.

Bronze Goacher's Crimson.—A bright reddish bronze form of the popular free-flowering Goacher's Crimson, and like it in all but colour. F.C.C., N.C.S., October 4. Messrs. W. Wells and Co., Merstham.

Virginia.—A splendid early decorative or market chrysanthemum of large size, and very free. The colour is white. F.C.C., N.C.S., October 4. Messrs. Lowe and Shawyer, Uxbridge.

Emperor.—Another large early decorative variety, with reflexing florets; crimson and gold. F.C.C., N.C.S., October 4. Messrs. Lowe and Shawyer, Uxbridge.

Miss E. Finch.—A single variety with large showy flowers of a rich terra-cotta colour. A plant shown demonstrated the good habit of the variety F.C.C., N.C.S., October 4. Mr. Frank Brazier, Caterham.

Eskimo.—A charming large early decorative or market variety, with well-formed creamy-white flowers, borne on long, stout stems. Commendation, N.C.S., October 4. Messrs. Lowe and Shawyer, Uxbridge.

Phœbe.—A large Japanese variety of soft silvery lilac-pink shade. Commendation, N.C.S., October 4. Mr. H. W. Thorpe, Worthing.

Roundabout.—A free-flowering border variety bearing an abundance of neat golden-bronze flowers. Commendation, N.C.S., October 4. Mr. H. W. Thorpe.

APPLE ELLISON ORANGE.

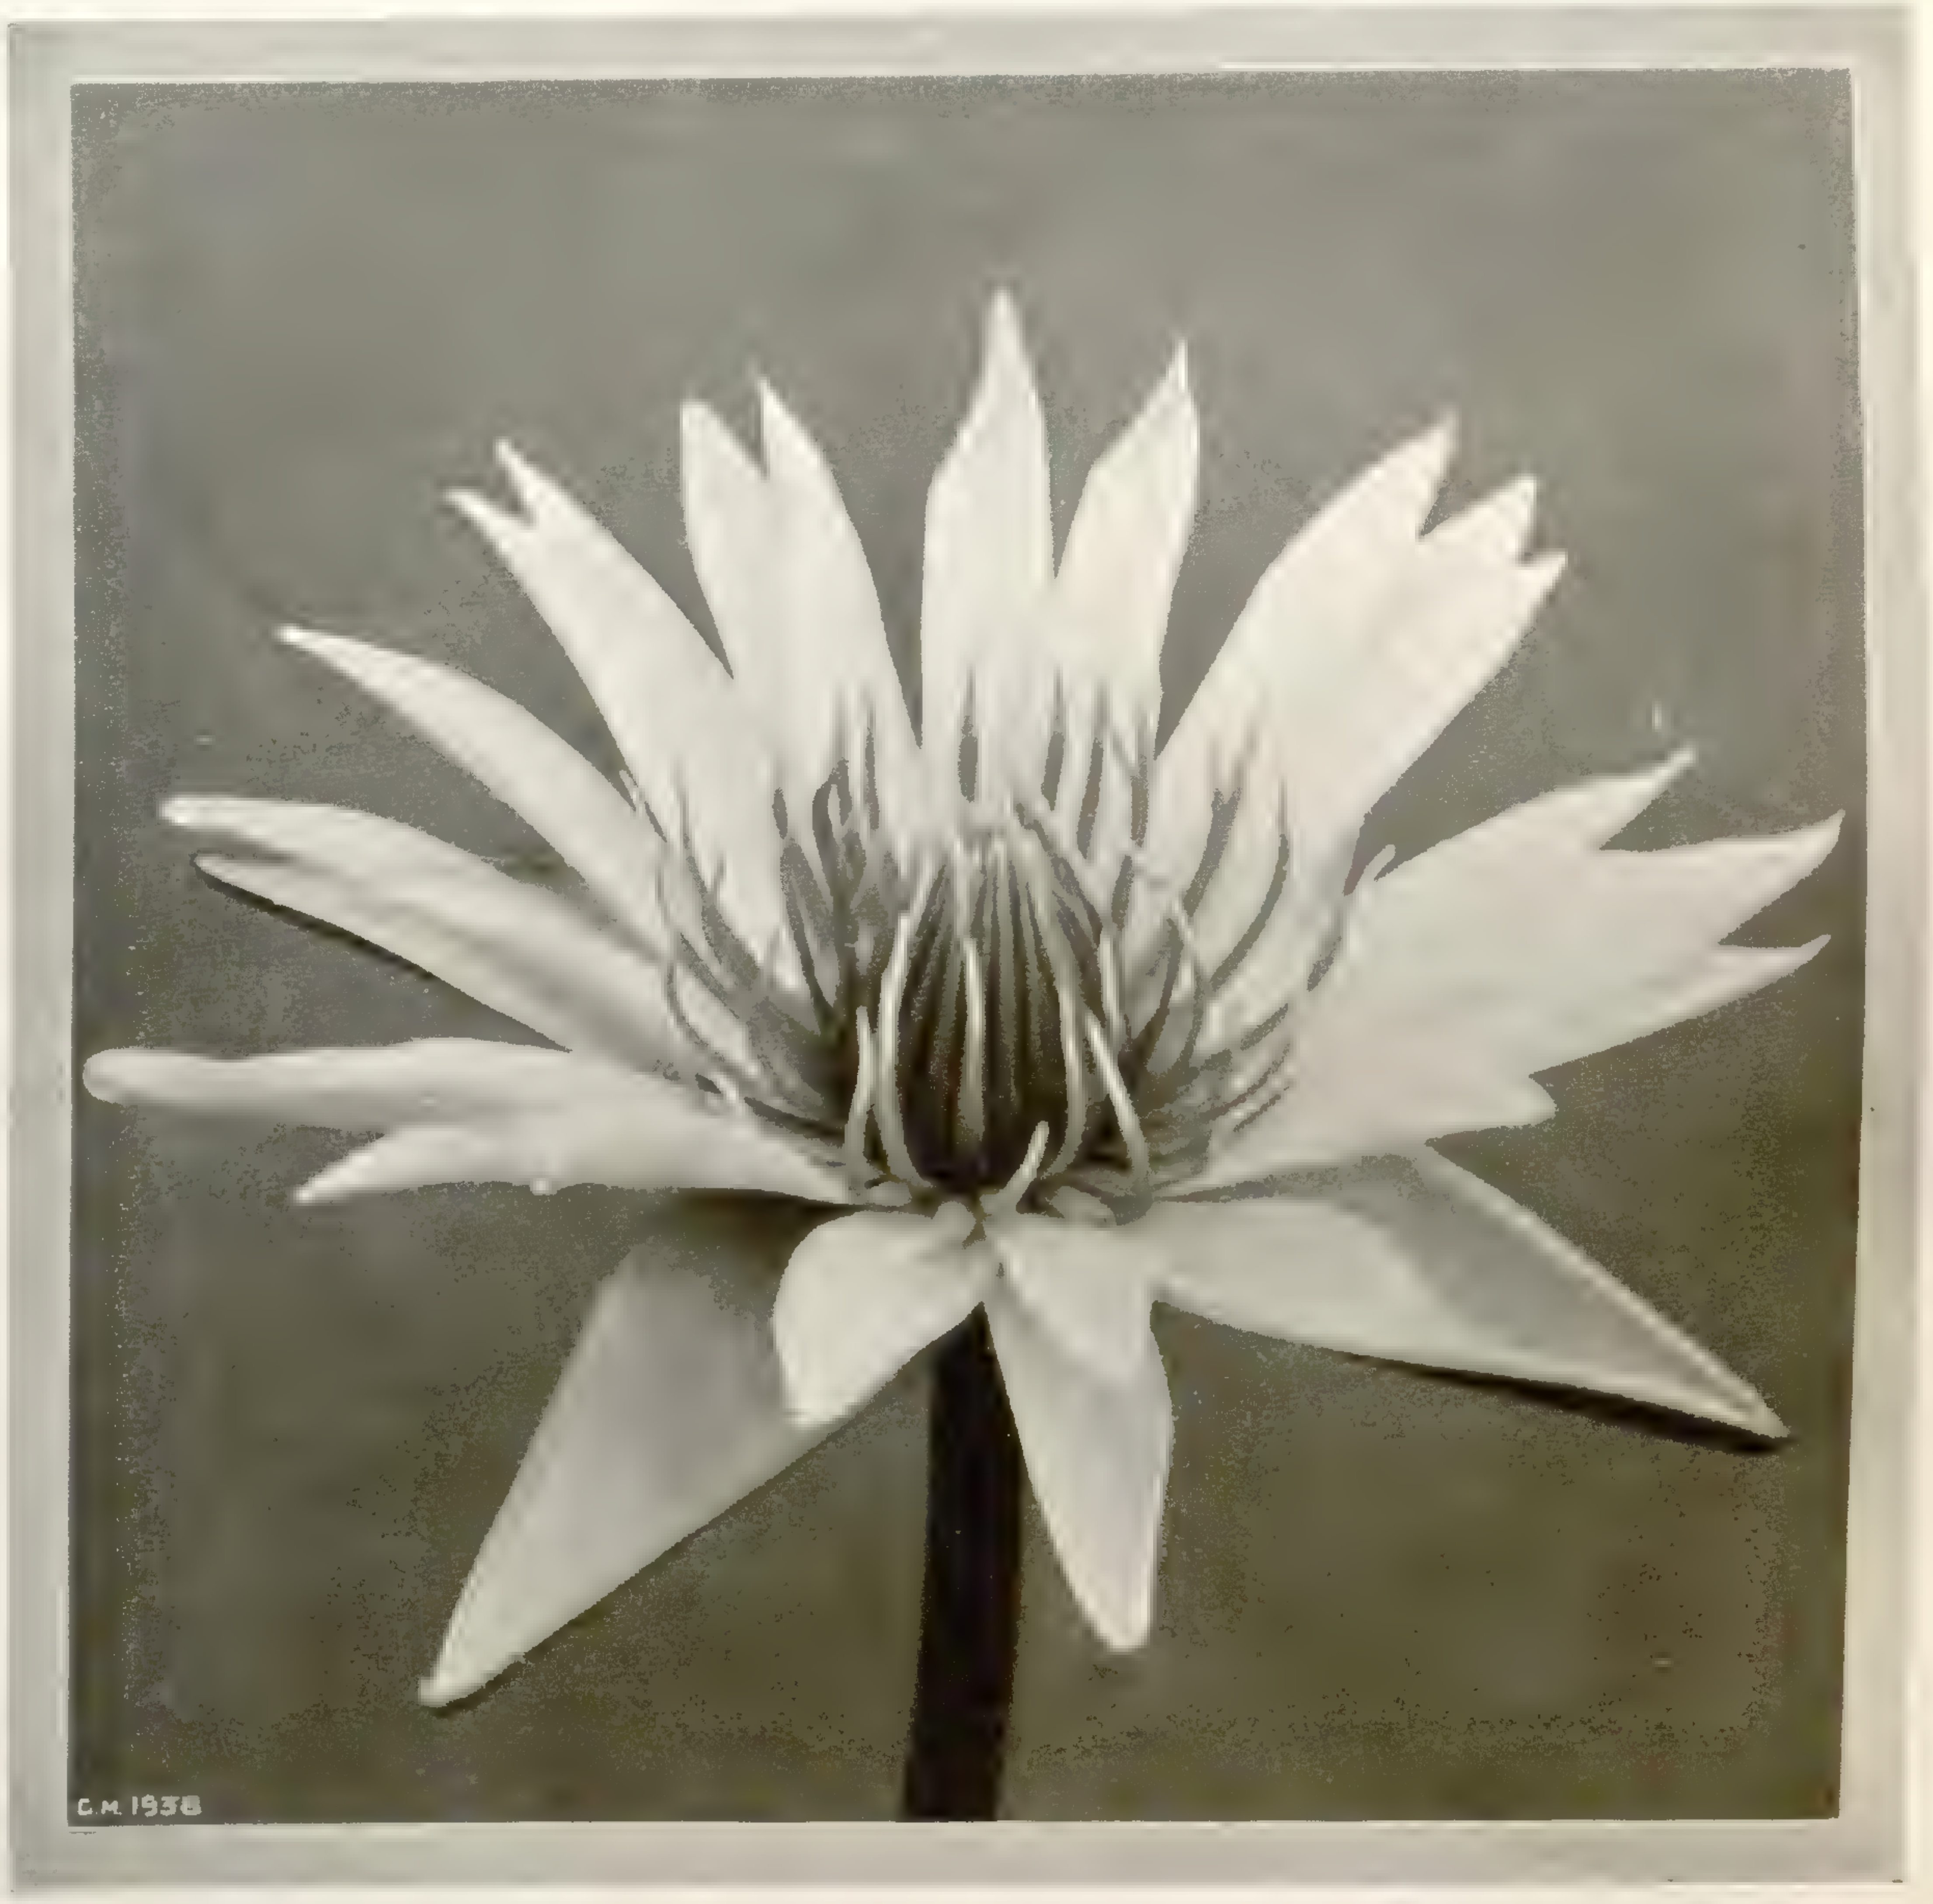
A finely-flavoured medium-sized dessert apple, in use during October. It was raised by the Rev. C. C. Ellison, Bracebridge, Lincoln, from Cox's Orange Pippin crossed with Calville Blanc. A.M., R.H.S., October 10. Mr. W. Crump, Madresfield Court Gardens, Malvern.

CUCUMIS METULIFERUS.

This handsome cucurbit hails from tropical Africa, and therefore needs a stove temperature when grown in this country. The fruits, from three to five inches long, are of a brilliant vermilion-scarlet hue when ripe, and the numerous thick fleshy spines add to their attractiveness. Bot. Mag., t. 8,385.

CYPRIPEDIUM SPECIOSUM.

It appears that the hardy orchid, so well known as Cypripedium macranthum, is generally C. speciosum, which, however, is closely allied to the first-named, and was regarded by Franchet and Savatier as a variety of it. So far as is at present known, the true C. macranthum does not occur in Japan, whereas C. speciosum is common in that country. The two species thrive under similar conditions. Bot. Mag., t. 8,386.



NYMPHÆA LISTERI.

A fine new nymphæa of the stellata section, with large deep blue, yellow-centred blooms. A.M., R.H.S., September 26. Earl of Warwick (gardener, Mr. H. Lister), Easton Lodge, Dunmow.

CLUSIA GRANDIFLORA.

A diœcious shrub, native of Guiana, this species is a member of a fairly large genus. At the Cambridge Botanic gardens it has flowered annually in a moderate stove heat, producing male flowers about five inches across, composed of six white rose-margined sepals, and eight wide rounded white petals. Each flower has about five hundred stamens grouped around a central gummy mass of yellow stamenodes. Bot. Mag., t. 8,387.

TORENIA ATROPURPUREA.

This pretty slender-growing species is from the Malay Peninsula. It makes a capital basket plant for a warm, moist greenhouse. In T. atropurpurea the tube of the dark purple flowers is narrowly funnel-shaped, more elongated than in well-known species, and tapering at the base. Bot. Mag., t. 8,388.

ACINETA MOOREI.

A rare South American orchid, allied to A. Heubyana. It first flowered at the Glasnevin Botanic Gardens in 1905, two years after its purchase as a distinct unnamed species. The pendulous flower scape carries about a dozen fleshy and rather globular flowers, pale greenish-yellow, freely spotted with brown; the lip is deeper yellow than the rest of the flower. Bot. Mag., t. 8,392.

MUTISIA CLEMATIS.

The mutisias are very interesting climbing composites, and many of them are good garden plants. M. Clematis is easily grown in a temperate house, though it never looks quite happy during the winter, and this may possibly be one reason why it is not more grown for conservatory decoration. It is evergreen, the leaflets being pubescent below, and slightly woolly above when young. The pendulous flower heads are about 2½in. long, and the attractive portion consists of nine or ten slightly recurved and brilliant red ray florets, each 1½in. long. M. Clematis is a native of the tropical Andes. Bot. Mag., t. 8,391.

MORMODES REVOLUTUM.

A quite handsome orchid introduced from Peru by Messrs. Sander and Sons, of St. Albans. It thrives in an intermediate house under the treatment found suitable for catasetums. Each spike carries many bright cinnabar-red, yellow-lipped flowers, these measuring from two to three inches across. Bot. Mag., t. 8,390.

CLEMATIS CHRYSOCOMA.

A low-growing Chinese shrub that has not proved quite hardy at Kew, this species has, nevertheless, much merit, and may be a useful subject for the south. The flowers are solitary, or there may be two or three together on very short leafy twigs, but the plant is very free-blooming, and the white, rosy-edged flowers are 1¼in. across. Bot. Mag., t. 8,396.

LANDOPHIA PETERSIANA.

Although this belongs to a rubber-producing family, its produce is of inferior quality. The species is a native of East Africa, and is a shrub that climbs by means of its inflorescence. The white, fragrant flowers have each five oblique, linear-oblong and ciliate lobes. Bot. Mag., t. 8,389.

VIBURNUM HENRYI.

Although this fine Chinese species, found by Mr. E. H. Wilson when collecting for Messrs J. Veitch and Sons, is effective when bearing its panicles of small pale greenish-yellow flowers in early summer, its period of greatest beauty is September, when the little fruits are brilliant coral-red, with here and there one turning black as it ripens. The plant is evergreen, and has proved hardy south of London. Bot. Mag., t. 8.393.

IMPATIENS HERZOGI.

This handsome species has flowers about two inches across and of a deep vermilion colour. At Glasnevin, where seeds were received from Dr. Schlechter, from German New Guinea, Sir F. W. Moore finds I. Herzogi amenable to cultivation in a remarkable degree; he has grown it in an odontoglossum house, in the dry atmosphere of a cactus house, and in a bright hot stove. In the stove it is seen at its best. Bot. Mag., t. 8,397.

ROSE BRITISH QUEEN.
A pure white hybrid tea, raised by Messrs. McGredy and Sons, Portadown

TRANSPLANTING PEACH TREES.

When cultivating peaches under glass it frequently happens that the trees need to be lifted and replanted from some cause or another. In the case of trees that have made growth too vigorously, it is preferable to lift and replant rather than to root prune, provided the specimens are not so large as to render the operation very difficult. The lifting can be successfully carried out at any time from now until growth commences, but the better plan is to lift and replant the trees before the foliage falls. By this means the roots are able to push into the soil before winter, provided the trees are regularly sprayed with clear water. During very bright weather a little shade will be an assistance to the trees after they have been transplanted. In the case of trees that have had their roots disturbed, a check to evaporation is important.

Experience teaches us that this early transplanting proves a material factor in the ripening of the wood, and I have known trees so treated to bear an abundant crop of fruits the following season, while others in the same house have failed to give satisfactory returns. Many experienced cultivators make a practice of lifting their peach trees every year as they find that only by so doing are they able to obtain satisfactory crops of fruit. While not advocating this plan, it is unquestionably in some cases the best means of bringing a previously barren tree to fruitfulness. When taking up the trees the branches should first of all be removed from the trellis and tied up loosely in several bundles with strong twine. The work of removing the soil must be done with great care, and a commencement should be made by opening a trench a fair distance from the tree to enable the soil about the roots to be forked into it. When all the roots are free, place the tree in its new position, and cut the larger roots cleanly with a sharp knife, so as to remove any damaged ends or undesirable portions.

When replanting good fresh loam should be used, with which has been incorporated half-inch bones and crushed charcoal. Make this moderately firm as planting proceeds, and lay cut the roots evenly through the soil, care being taken to avoid burying them too deeply.

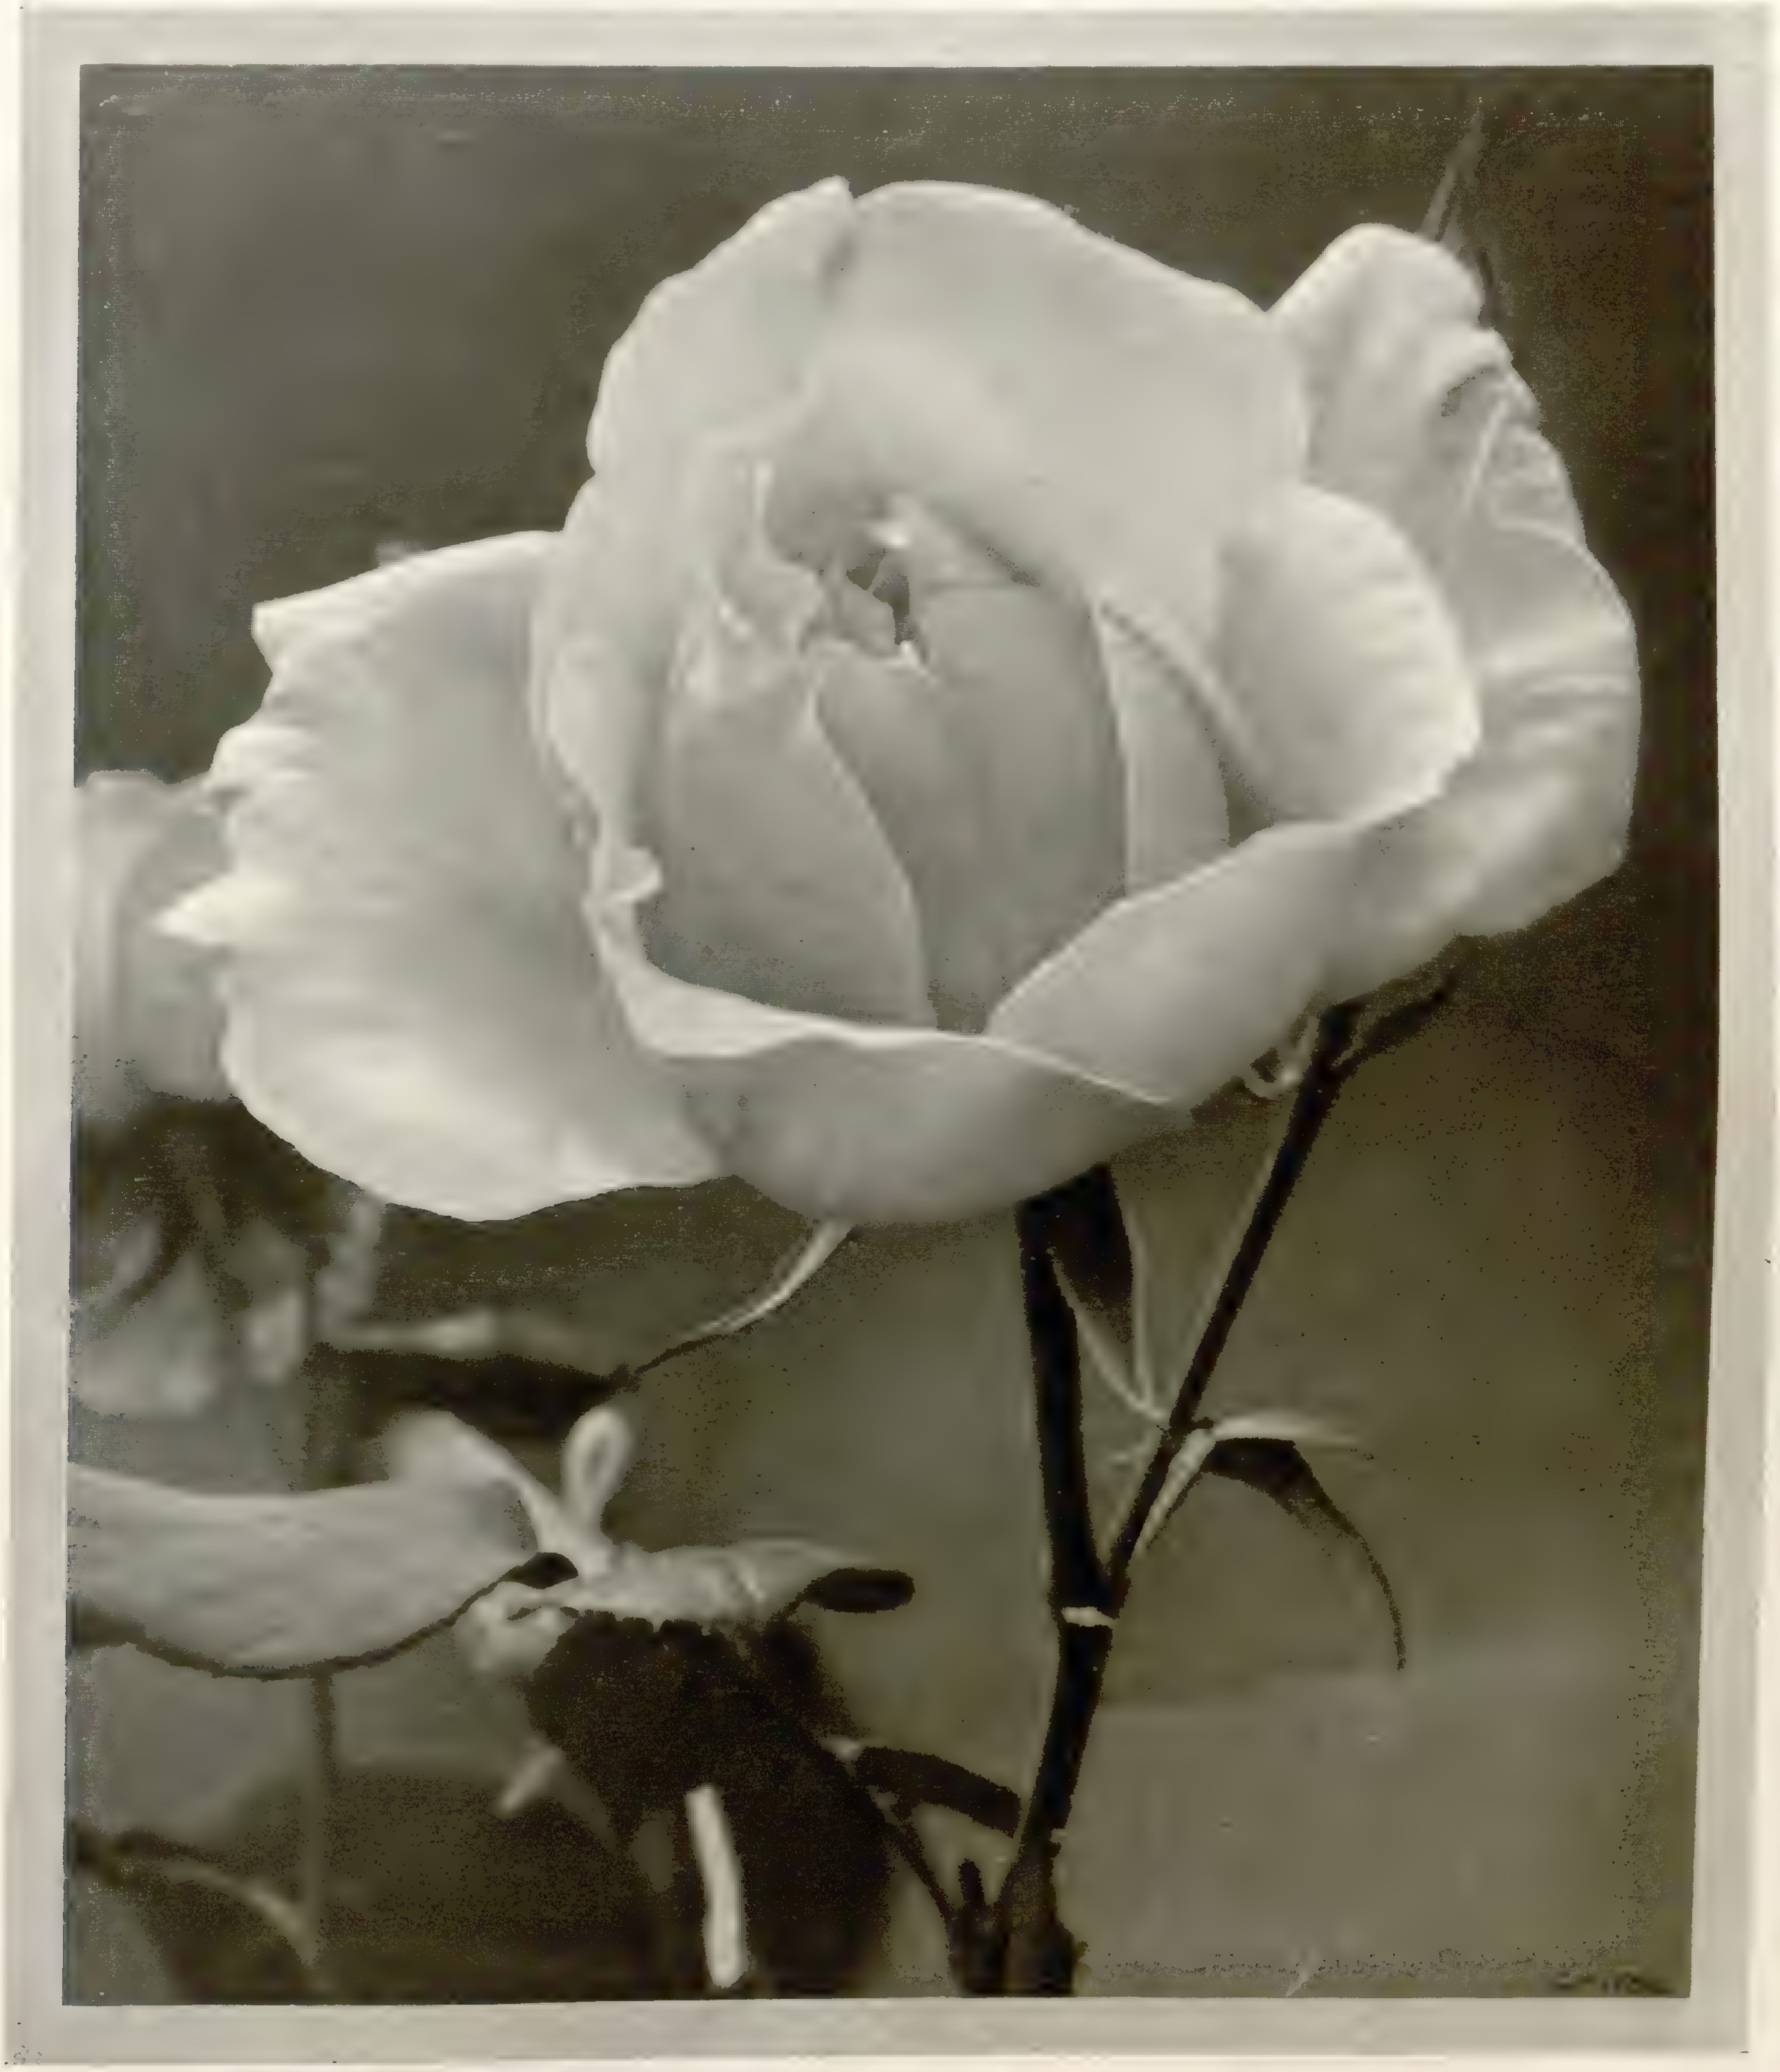
When the planting is completed and the soil made firm, give the border a good watering to thoroughly settle the soil about the roots. One of the mistakes in peach culture is to plant the trees in a very deep or large border, but if they have a fairly restricted root area much better growth will be produced, and more regular crops be obtained.

J. Gardner.

Batsford Park Gardens.

THREE NEW ROSES.

During the spring and summer of the current year we have figured a number of new roses that have been presented to public notice, and we now have the pleasure of giving illustrations of three others that have favourably impressed us with their distinction and beauty and their other good qualities. Taking them in alphabetical order, we have first,



ROSE MAGNOLIA.

A beautiful hybrid tea with soft white flowers, raised by Messrs. Paul and Son, Cheshunt.

British Queen.

A charming hybrid tea, raised by Messrs. McGredy and Sons, of Portadown, Ireland, and shown by them at the exhibition held by the National Rose Society in the Royal Botanic Society's Gardens on July 7. The blooms are of fine form, as so well shown in the accompanying illustration, large in size, of the purest whiteness, and remarkable for their depth and breadth of petal. It was awarded a Card of Commendation at the above exhibition, but in a more favourable season it is reasonable to assume that it will obtain a higher award.

Cinderella.

Some of the newer rambling roses of the Wichuraiana group are particularly dainty and pleasing, and seem especially adapted for cultivation in pots under glass for the purpose of providing elegant floral specimens during the spring-time. One such is Cinderella, here figured. Out of doors it is a late flowering rambler, and therefore it has special claims for attention from those who desire to maintain as continuous a supply of roses in the garden as possible. The variety is a robust grower, and its large light clusters of deep pink blossoms have a peculiar grace. The flowers are well doubled, and in many cases the ends of the petals are somewhat quilled. The shade of pink seen in Cinderella is deeper than that found in the popular Lady Gay, and when large specimens are freely flowered, like those so finely exhibited by Messrs. Wm. Paul and Son, of Waltham Cross, at the Temple Show in May last, they present a picture of the utmost beauty—not Cinderella in the kitchen, but Cinderella, exquisitely dressed, at the ball.

Magnolia.

The illustration herewith so admirably portrays this beautiful rose as to render more than the briefest description unnecessary. The variety belongs to the ever-increasing list of hybrid teas, and has the promise of proving a valuable addition to the finest of the varieties that are already in general cultivation. The blooms are of large size and fine form, and are especially remarkable for their depth and breadth of petal. The colour is soft white, and very pleasing, and its delightful perfume will give it a prominent place among the varieties that are especially valued for their fragrance. The raisers are Messrs. Paul and Son, of Cheshunt, who have enriched our gardens with many roses that are of special value for decorative purposes.

ROSES FOR HOUSE WALLS

With the exception of an odd plant or two, roses are not much grown upon the walls of the dwelling-house. Why, it is difficult to say, except that apparently walls are required for other plants of a climbing habit. There are many choice varieties of roses that would never be seen and enjoyed at all if it were not that they were grown against walls, for the reason that, owing to some constitutional defects, they will not succeed in the open. When planted at the foot of a suitable wall, and their branches trained over its surface, they are most attractive, and when so grown it is the only opportunity afforded of seeing such varieties in perfection. For covering high walls quickly it is difficult to suggest other plants more suitable, as growth is quickly made under favourable cultural conditions. In fact, so rapid is their development that I do not know any climbers that can be planted with greater advantage.

There is one reason, perhaps, why we do not see some roses growing against walls, and it is that the varieties usually planted are so unsuited for the purpose. For instance, a lovely rose though it is when seen in good condition, Gloire de Dijon is apt to become untidy, bare of growth, and later on sparse in blossoming. Then, when it is severely pruned and induced to push forth vigorous shoots, it again blooms freely and clothes the wall with healthy foliage. While this renovation is in progress the wall presents a bare and uninteresting appearance.

The newer type of roses, namely, the Wichuraiana section, provides abundant varieties most suitable for covering walls quickly, but I would hesitate to recommend these varieties for the simple reason that their inclusion amounts to almost a waste of wall space, because they succeed so gloriously in the open. Wall spaces should be reserved for roses that fail to grow and bloom satisfactorily in the open in the majority of instances. The yellow Banksian and Celine Forestier may be mentioned as examples. I would also suggest that where possible, varieties that are nearly evergreen should be employed with a view to rendering the wall a little more interesting during the winter months. Climbing Aimée Vibert may be mentioned as an example of the class of roses that is especially suitable for walls. Roses will succeed against walls of any aspect, but that with a southern exposure is naturally to be preferred as giving the greater warmth, tending to the successful growth of the most fickle varieties in an ordinary way. South walls, thirty to forty feet high afford abundant scope for really fine displays at various periods of the year, and under such conditions the culture of old favourites is rendered very interesting.

Soil Preparation.

A thorough preparation of the soil is even of more importance for wall culture than out in the open, because during hot and dry weather the roots are more likely to suffer from want of moisture, owing to the naturally warm position and also to the extraction of moisture from the soil by absorbent bricks. Too often at the base of a newly-built house, the material is largely composed of shavings, broken bricks, mortar, and such like; all this should be removed preparatory to planting, to the depth of at least three feet, and replaced with a compost of rather stiff soil or turf with a free admixture of half-rotted manure; if the latter is from the cow-house all the better. In the case of an old building where other kinds of plants have been growing in the border at the base of the wall, the soil should give place almost entirely to new compost. Where no plants have been growing manure freely added while trenching is being done will suffice. In all cases remember that luxuriant growth gives the best results, not only by quickly covering space, but in giving a full crop of flowers also.

The end of October or early in November is a good time to plant roses in such a site; dwarf, stocky plants are the most suitable, as they will, with proper pruning, furnish the space quite from the ground. Where the plants are growing in pots, March or even April is a good time for planting. It may indeed be done at any convenient opportunity at a later period than is here mentioned, but there will be an advantage in planting in the autumn.

Pruning.

Pruning the plants rather hard the first season is a wise method, to induce basal growths for the purpose of completely furnishing the walls at the bottom; without close pruning at planting time such growth cannot always be assured.

The subsequent cultural directions are but few. An abundance of moisture at the roots during the time the main growth is being made is all-important; copious supplies of liquid manure are of the utmost value also. Artificial supplies of water on a liberal scale will be necessary, for when roses are growing in borders at the foot of a wall, the roots receive a portion only of the rain that falls because of the shelter given by the wall. This point cannot be too strongly impressed upon those who have roses growing against walls, and especially when the eaves of the house extend some distance from the wall. Keeping the foliage tree from insect pests, such as greenfly, especially by a timely application of an approved insecticide, is an absolute necessity. In the same way should red spider be suppressed at the end of the summer, when this insidious pest is much too common in some seasons. Vigorous syringing of the leaves during spring and summer is highly beneficial, but it is frequently neglected by many. It also often happens that plants which have been growing several years receive little assistance from manurial matter, either solid or liquid, with the result that the soil becomes exhausted of its plant food, and the roses fail to make suitable growth or to produce a satisfactory crop of flowers. The grower of hybrid teas in a rose bed would not expect them to continue in a vigorous condition for years without aid of some sort, and why they should expect wall plants to differ in this respect is difficult to understand.

Pruning established plants needs much care; in the case of strong-growing varieties like Félicité Perpetué, the weaker growths should be removed directly flowering is over to admit air, light, and sunshine to the remaining growths; but when the wall space is covered with suitable branches a system of spur pruning should be adopted, the subsequent growths yielding satisfactory results. Early training of the shoots is also an important detail. When they are allowed to grow into a thick, tangled mass it is most difficult to separate the growths without injury to those remaining. They should be secured quite early, regulating them thinly over the allotted space.

Selection of Varieties.

One of the first varieties the inexperienced cultivator selects is Crimson Rambler, owing to its brilliancy of colour, but as regards utility it is quite the worst of all for a wall. I have not yet seen a respectable specimen of it trained to a wall, and this is explained by the fact that cooler conditions are required for this grand rose than a wall—especially one with a southern aspect affords—the trees refuse to grow, and are quickly covered with red spider.

For a South Wall.

Yellow Banksian is one of the most delightful of early free flowering roses in cultivation. With good treatment this rose will yield an abundance of flowers annually, and grow as much as fifty feet high, and will remain in good condition fifty years, or even more. The white form is not nearly so free flowering, but where it succeeds it is very attractive.

Rêve d'Or, sent out in 1869, is a noisette, not nearly so much grown as its merits deserve; the deep yellow blossoms are most freely produced, and harmonise delightfully with the coppery-tinted foliage. When the wall space is covered—which it quickly is, as the growth is luxuriant — the plant should be closely spur-pruned, as from the current season's growths the finest flowers are produced, and the most satisfactory foliage also. When the shoots of the previous year are retained the blooms resulting are small and pale in colour.

Lamarque, noisette, sent out by Marechal, 1830, is one of the most free-flowering of the varieties we have with large blooms. The warmth derived from a south wall seems to aid the ripening of the wood, and induces free blooming. Under glass this is a pure white rose bud, but in the open the colour is pale lemon or cream. Huge clusters of sweetly-scented flowers are produced, with ample leafage.

Celine Forestier is another noisette—sent out in 1858—that we can grow with the aid of a south wall, and much too charming a rose to neglect when such wall space becomes available. The pale yellow blooms are deliciously scented, and produced in clusters in conjunction with good foliage present a very pleasing appearance.

Fortune's Yellow is now seldom seen in the open, and not under glass as much as its merits deserve. The yellow semi-double flowers are heavily flaked with carmine and most fragrant. On a south wall it succeeds grandly.

Banksiæfolia belongs to the sempervirens class, a rose seldom seen, but for a wall it is charming. The growth is free, with excellent foliage, and the clusters of flowers, white with a buff centre, are freely and continually produced from July until November. It is a really perpetual-flowering rose, with a delightful perfume all its own.

Cloth of Gold.—The flowers of this variety are sulphur-yellow, with deeper centre, and they are large and double, but they are not very freely produced.

Sinica Anemone is a fine single-flowered rose, white flushed pink. The individual blooms are large and handsome.

Maréchal Niel is still the king of yellow roses; some of the finest blossoms I ever saw were growing on a south wall in Yorkshire. In the South it also succeeds. Liberal treatment is required. Plants budded on the common brier are preferred to those on their own roots, as they are more vigorous.

For a West Wall.

Reine Marie Henriette gives an early crop of deep cherry-red blossoms; commonly known as the red Gloire de Dijon.

Mdme. A. Carriere.—This is an early-flowering variety, and the production of blooms is free and continuous. The leafage is good, and the flowers are white, tinted blush.

Climbing Aimée Vibert.—This is a pure white noisette, producing its blooms in clusters, and flowering in the autumn. The effect produced by the flowers is much enhanced by the dense deep green foliage, which is greatly improved by liberal treatment.

William Allen Richardson seems to have fallen out of favour of late, mainly owing to the general pale colour of the flowers. On a west wall the colour, deep orange-yellow, is fully brought out by free growth.

Gloire de Dijon succeeds remarkably well on a west wall; the cooler conditions prevailing here suits this variety better than a southern exposure.

For an East Wall.

Ards Rover, crimson, shaded maroon, is one of the best of early-flowering roses, yielding its shapely buds in quantity. A close system of spur pruning when the allotted space is covered is an absolute necessity. Then it is not easy to say how long this variety will continue to thrive.

For a North Wall.

Against a north wall it is difficult to grow roses, except under the most careful treatment, and by maintaining thinness of the branches. Gloire de Dijon succeeds, but the best variety that I know is Félicité Perpetué, which has creamy-white flowers borne in huge clusters. It is most free in growth, and almost evergreen. I need hardly say that this rose succeeds better on a south wall.

The Wichuraianas, of which Dorothy Perkins is still the best, will succeed admirably on a northern aspect, making free growth, and as the foliage is practically evergreen they are most useful, covering the walls during the greater part of the winter. Réné André is another variety that succeeds; but, of course, no one will expect the same profusion of flower from that aspect as from another.

Varieties like Climbing Mrs. W. J. Grant, Captain Christy, and Caroline Testout, although classed as climbers, are most unsuitable for walls, as they quickly become devoid of flowering shoots and leaves, making gaunt specimens with a few struggling blooms at the apex. E. Molyneux.

Swanmore Park.

Æschynanthus Lobbianus. —The genus Æschynanthus is a fairly extensive one, nearly all its members being natives of South-Eastern Asia or the neighbouring islands. They are all of more or less shrubby character, and occur in a state of nature principally as epiphytes, and belong to the natural order Gesneriaceæ. The species above named is one of the best, forming as it does a loose-growing plant that may be grown supported by a stick in an upright manner, or in a suspended basket. The ovate leaves are small, and very dark green, while the rich scarlet flowers protrude each from a dark-coloured, thimble-shaped calyx. Nearly all the members of this genus flower during the autumn months, others now in bloom being Æ. grandiflorus, orange and crimson; Æ. pulcher, scarlet; and Æ. speciosus, orange-red with dark markings.—W. T.

HOW AND WHEN TO FEED ROSES.

There are very few subjects that give a better return for generous treatment than roses, but feeding should be done with more thought to the natural fertility of the soil than is usually the case. To add a large quantity of what is already present is often unnecessary and harmful.

That any special soil is absolutely essential is not borne out when we consider the vast range and variety of soils the superb blooms come from for the exhibitions of the National Rose Society. Nor is it compulsory they be grown in pure country air, as was once insisted upon, for do we not have classes for those grown within six miles of Charing Cross?

Granting, then, that roses can be grown in a variety of soils, it will be well to consider some of the best and most efficient ways of making these more suitable, and there could be no better time than when preparing for new plantations, because we can never get at the bottom soil when once the roses are planted.

Upon ordinary soils, thoroughly rotted stable manure is one of the safest and best additions. Perhaps the most powerful manures are pig dung and night soil. Neither are so pleasant to use as clean stable manure and some of the artificials, but they can be utilised with little offence if properly prepared. The ashes and burnt earth from the ordinary garden refuse fire may be run through a coarse riddle and the manure mixed with this, turning it over two or three times before use. The burnt earth and ashes are grand fertilisers for roses, and when mixed with these manures in about equal proportions make what I consider the best of all manures. They are not suitable for mulching because of their odour; nor am I at all in favour of much mulching among roses, the pleasure of walking among them being heavily discounted thereby.

RAMBLING ROSE CINDERELLA.
A Wichuraiana variety with deep pink flowers, that has been well exhibited by Messrs. Wm. Paul and Son, Waltham Cross.

Whatever the nature of the soil may be it should be dug deeply, and laid up to the air as long as possible before planting. Eighteen inches to two feet is not too much to move. If very stiff a little drainage may be necessary, but almost as much depends upon the class of manure to be used. Stiff and naturally retentive soils should have the help of lighter manures than pig dung or night soil. Stable manure, burnt refuse, and soot will be more suitable; also crushed bones, not the finest bonemeal, but half and quarter-inch bones. Place this among the soil in the bottom trench where it will help to drain and feed at the same time. The action of bone manures is steady and lasting, so they are of little use for hurrying growth along.

I have found blood manure much the best for use when the plants are in full growth, but it should either be used in a liquid state or hoed in during showery weather. It is not only offensive if left on the surface, but a great deal of its strength evaporates quickly.

A mixture of manures is very beneficial if we take care not to mix those of an antagonistic nature. Well-rotted leaves and clean weeds, vegetable refuse and old potting soil, may have horse, cow, pig, and fowl manure all mixed up and turned over with them a few times previous to use. There is scarcely any soil that this will not benefit greatly, while it is always safe. In spite of repeated warnings, far too many place strong manures in close proximity to the roots when planting. It is wise to let the roots grow freely and find their own food, and I am certain many have courted failure by placing manures directly upon the roots.

Mulching, according to my experience, is best done early in the spring, just when new roots are starting. Autumn and winter mulching is comparatively wasteful, so much of the fertilising properties being lost through percolation before the roots are active enough to make use of them. Nor do I like the presence of wet material around the plants in winter, feeling sure we protect better, in most instances, by keeping the base of the plant dry. Cow manure, when laid up and well rotted, makes a capital manure for light soils, but I do not care to use it very fresh. This applies to all natural manures, whereas those of artificial manufacture should be used as freshly as possible.

The chief point in connection with newly planted roses is to secure a sufficiently rich bottom soil to sustain the roots, rather than let them get into bad subsoil, which they would be sure to do, more or less, as time went on. There is nothing like a good start. I have great faith in surface feeding, especially while the plants are in active growth. Frequent applications of weak liquid manure are much better than a few strong doses.

Bone manure in various forms is the only safe artificial manure for newly-planted roses; others should be withheld until the plants are in active growth. Guano, blood manure, and most artificials are best sprinkled over the ground during wet seasons, and lightly hoed in as soon as the ground will permit. But they are of very little service when used dry during such a summer as that of 1911. Apply artificials in a liquid state, and do not fear to use them freely, of course, paying due attention to the directions given by the vendors. It is not safe to state quantities without knowing the strength or freshness of the manure. A number of manures are advertised in these pages, and all are good if used as advised; if not, the vendors would scarcely receive repeat orders, and an old and well-known patent manure recommends itself by that fact.

Under glass we need to study the soil just the same as in the open. Weak and frequent supplies of liquid manure are needed during growth—both while the plants are in flower, and when making the vigorous summer shoots that will supply the main crop of bloom in the coming spring. A surface-dressing of fertiliser, slightly covered with fresh soil, is very serviceable for pot plants. I am also much in favour of using the drainings from a cow stall, taking care this is not used very strong.

Finally, I think we may sum up by saying roses like almost any manure, but would rather have quantity than great strength. I have found pigeon and fowl droppings very rapid and powerful in action, but they should not be wetted until applied. I consider them best in a liquid form, because the ammonia escapes if they are exposed to the atmosphere when damp. Ashes, burnt soil, or even dry garden soil is much to be preferred in the chicken run to lime, as the latter releases almost all of the fertilising properties as soon as it comes into contact with the droppings.

Rosarian.

RAMPANT CLIMBING ROSES.

Among the many useful purposes for which the hardier and stronger-growing kinds of rambler roses may be employed is the covering of trunks and branches of trees, especially when bare or decrepit, either in the garden itself or in its outskirts, when the latter consist of woods and plantations. Given a proper amount of light and air for the encouragement of the growth and ripening of the wood, very pleasing results may be obtained by planting roses in such situations; in the case of tall trees a picturesque and artistic effect will be produced by the mingling of the rose branches with those of the tree itself, and by the ever-varying clustering and hanging forms they will assume, whilst shorter trees will very soon become entirely covered, and present a charming prospect of tender green in spring, with an almost unbroken mass of colour in the flowering season.

In order to secure the fullest measure of success in the employment of roses for this purpose, especial attention must be given to the provision of good soil for them to grow in, and of the requisite amount of moisture at the roots for the support of the plants. The importance of making these provisions becomes apparent when we consider that the roots of the tree itself, if living, are apt to absorb the greater part of the circumjacent nourishment and moisture in the soil; and even if the tree should be dead or moribund the action of the roots in the past will have tended to the impoverishment of the surrounding soil, to say nothing of the effect of the branches in keeping off the rain in their immediate vicinity. In planting climbing roses therefore in such positions liberal diet must be provided for them in the shape of stations two to three feet square, and as much deep, filled with fresh soil and manure, and yearly mulchings of the latter should be given after the first two years' growth. Moisture can, of course, be afforded artificially at any time during the growing season, according to the weather, and whilst stagnation of water in the soil is to be avoided, it must be borne in mind that the evaporation from the large leaf-surface of a climbing rose in full growth is considerable, whilst the enormous masses of flowers produced by a vigorous plant demand from the roots a plentiful supply of liquid nourishment for their proper development.

With a view to obtaining a good effect within reasonable time, it is well to plant more than one rose to each tree; three is a good number, placed at equal distances from each other round the stem, and at a distance of from two to three feet from the stem itself.

As regards the height to which climbing roses will ultimately attain in such positions, much will naturally depend upon the varieties employed, as well as upon the situation and the completeness with which their cultural requirements can be complied with; but under ordinary favourable conditions the most vigorous kinds may be expected to reach a height of from twenty-five to thirty feet, and sometimes more. To prevent the base of the roses becoming bare, as is liable to be the case, it is well to employ plants on their own roots, as these throw up a succession of shoots yearly from the roots, which serve to furnish the base of the plant as well as to take the place of any of the older branches that may die in the course of time.

Very beautiful objects in the garden can be produced by covering worn-out fruit trees with climbing roses; if the fruit trees have been of the bush or pyramidal shape a little shortening of the branches will serve to give a symmetrical form without too great a spread of surface; and by planting three roses to a tree, and tying in the shoots as they grow to its branches, the roses will quickly clothe the tree and rise to its summit, when the shoots will naturally fall over and present a gorgeous effect when in flower.

As absolutely hardy kinds of roses of great vigour of growth that are suitable for covering trees the old-fashioned white and blush-flowered varieties of the Ayrshire and Evergreen classes are still some of the best; Dundee Rambler, Félicité Perpetué, Flora, Leopoldine d'Orleans, Myrianthes Rénoncule, Thoresbyana, and Virginian Rambler are all excellent. The single-flowered type of Rosa multiflora (the bramble-flowered rose), and its hybrid variety, Grandiflora, are also excellent, and of the more recently introduced kinds of multiflora and Wichuraiana origin, some very suitable sorts are Aglaia, yellow; Alberic Barbier, pale yellow; Blush Rambler, pink; Crimson Rambler, Dawson, pink; Dorothy Perkins and Lady Gay; Excelsa, crimson; Gardenia, pale yellow; Helène, pale pink; Hiawatha, crimson; Jersey Beauty and Joseph Billiard, beautiful single-flowered kinds with pale yellow and bronzy-red flowers respectively; Leuchtstern, pale pink; René André, coppery rose; Rubin, deep red flowers and beautiful crimson-tipped shoots; Waltham Bride, snow white; and the type or species of Rosa Wichuraiana, which has pure white single flowers with yellow stamens. The summer-flowering hybrid, Carmine Pillar, is also very beautiful, although the flowers are somewhat short-lived, and the hybrid musk The Garland, pale buff, and Seagull, white, are both excellent. In sheltered positions some of the strong-growing hybrid teas may be planted, such as Climbing Captain Christy, Madame Berard, and Reine Olga de Wurtemburg.

Some other picturesque forms in which the strong-growing kinds of rambler roses may be advantageously used in the garden are in the clothing of tall posts or pillars, where these are in harmony with the surroundings, and also for covering large spaces on trellises. For these the foregoing cultural hints would also apply, and the varieties of roses above-mentioned would also be very suitable.

Waltham Cross. Arthur W. Paul.

Clematis integrifolia.—This is a very beautiful hardy border plant, flowering freely in June, July, and August. The flowers are blue and borne on plants about 20in. high. It is readily increased by division when growth commences in spring. An open, loamy soil suits it best, and, if fairly rich all the better. Poor soils can always be enriched at this season of the year by pointing in some well-rotted manure and better loam. In the early part of spring a light surface mulch will be beneficial, and also a small quantity of old lime rubble and sweet leaf-soil in cases where the soil is retentive or low-lying.—G. B.

NOTES ON GROUPING ROSES.

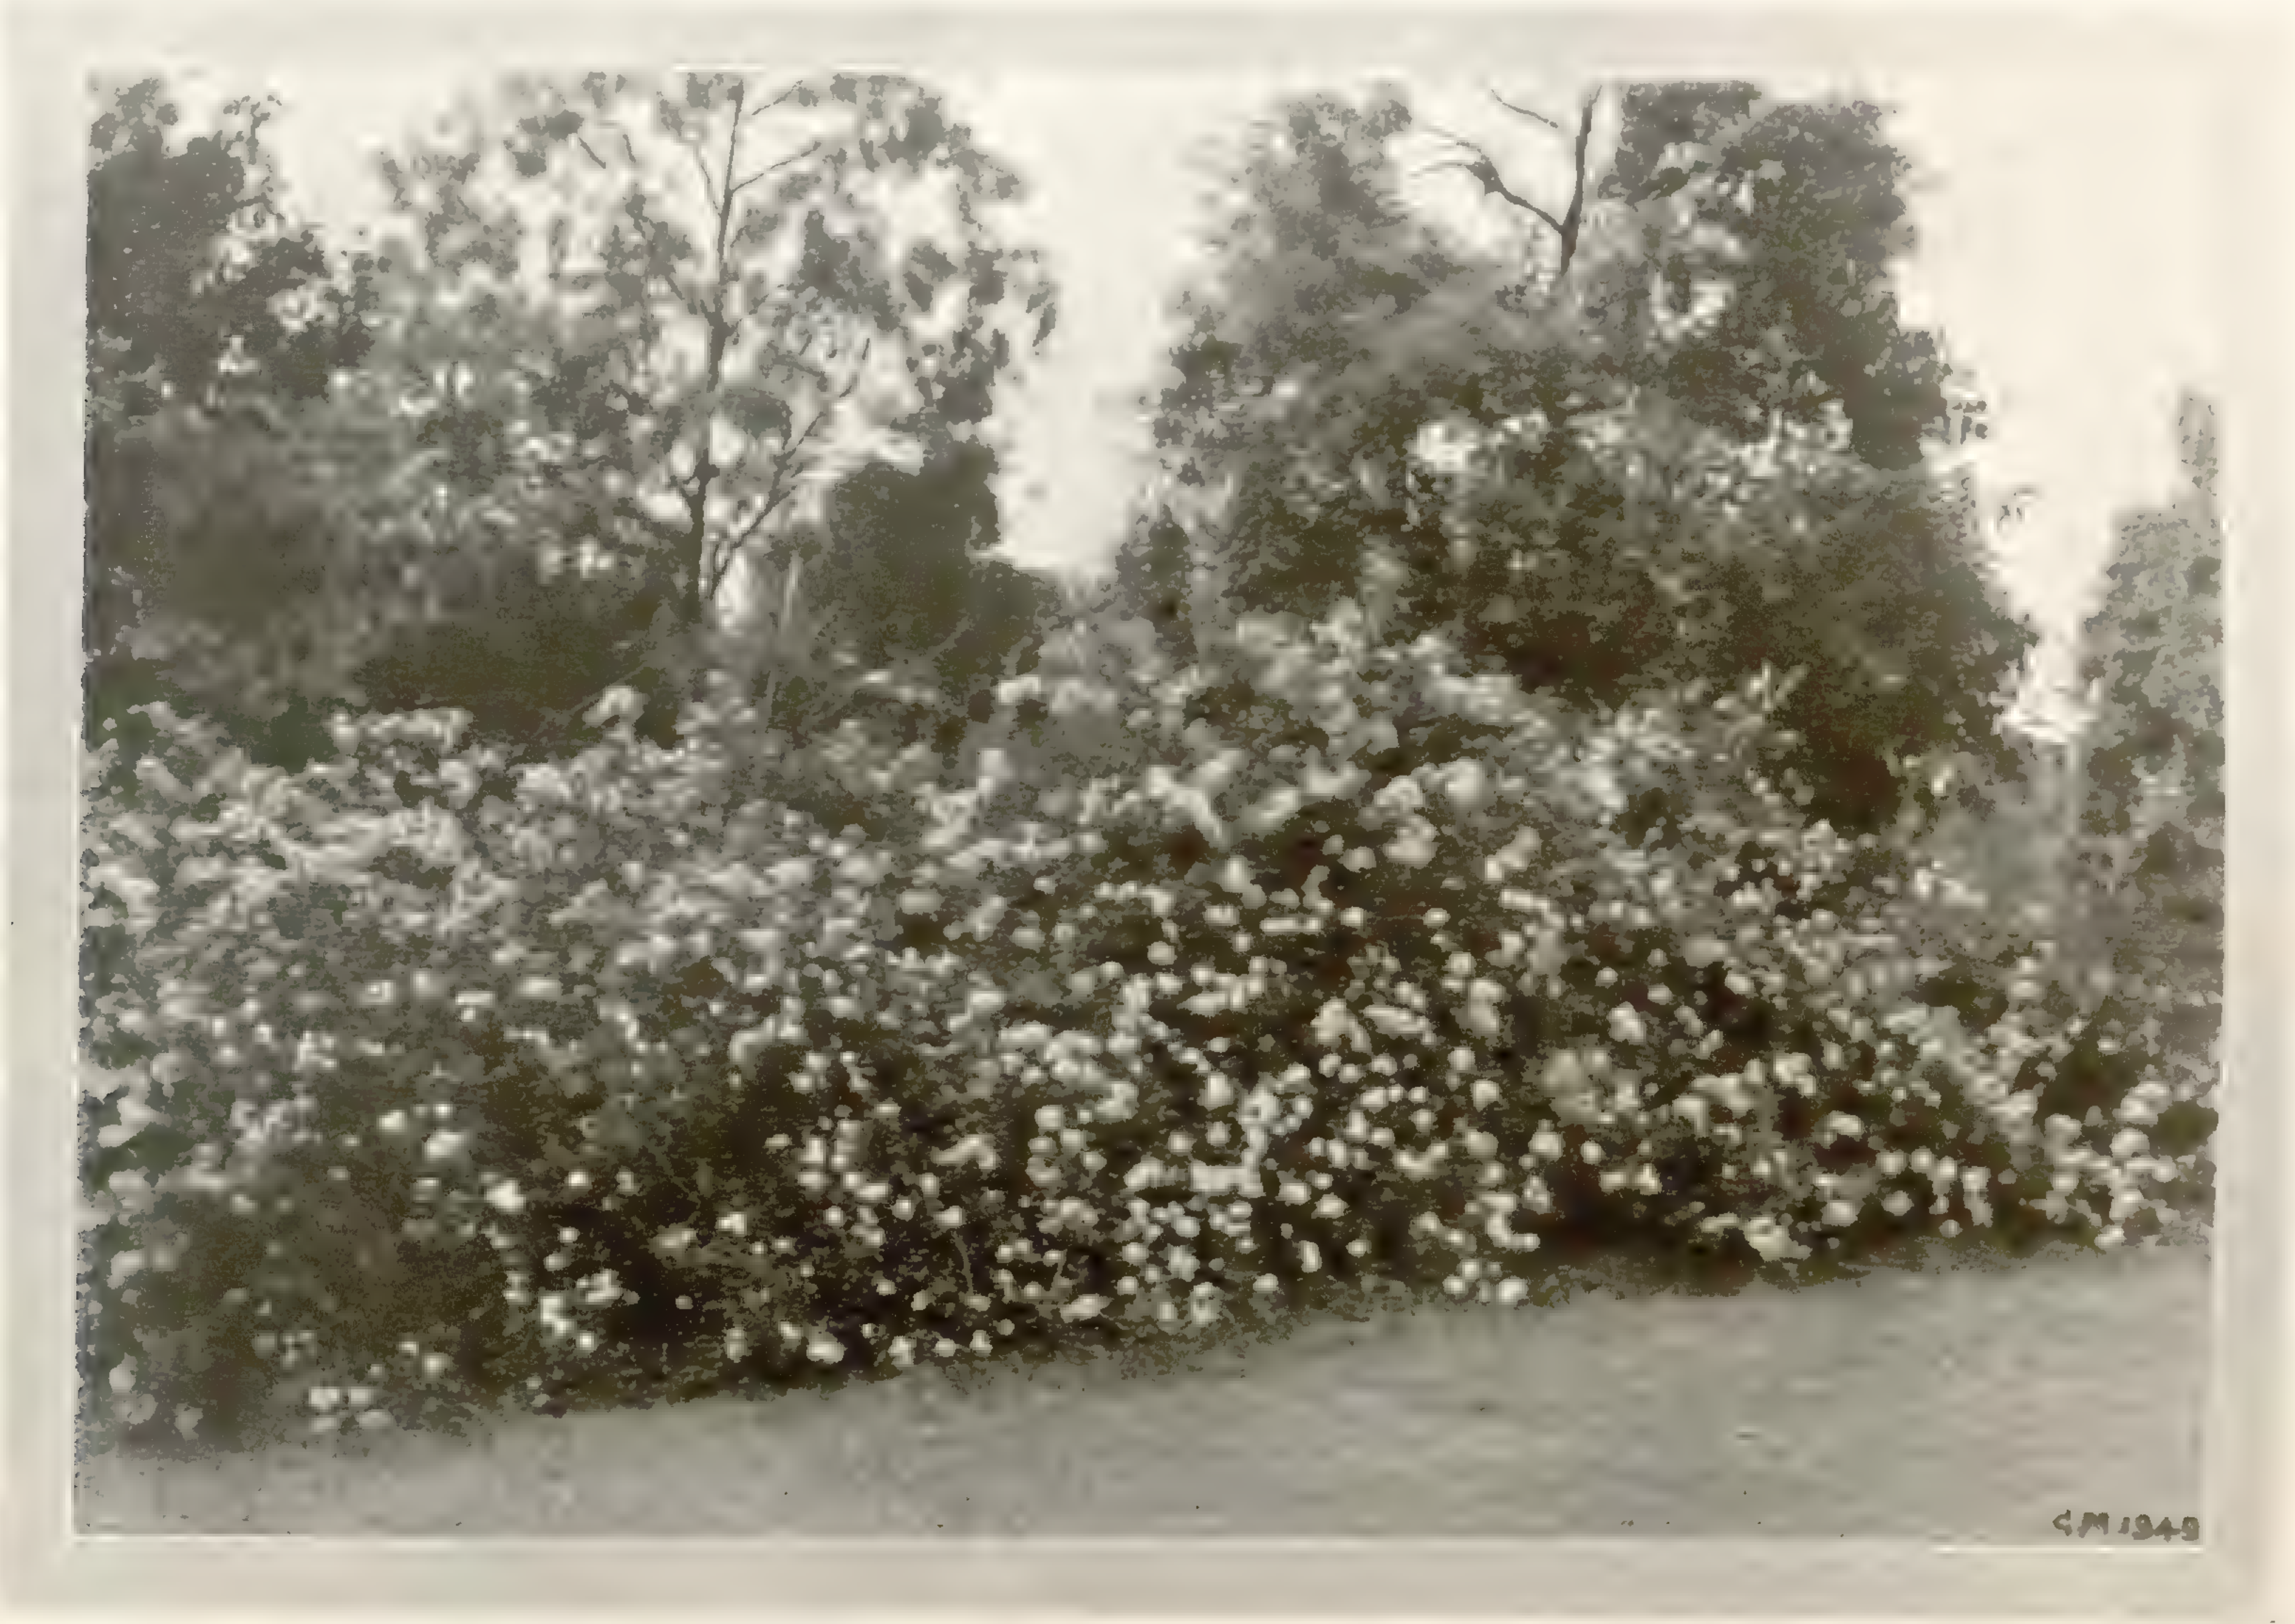
There are so many methods of grouping roses by which the most charming effects can be obtained that much space would be required were any considerable proportion of them described in detail. A detailed description will not, however, be attempted, as the chief object of these notes is to call attention to an excellent way of forming groups of the Wichuraiana varieties now so deservedly popular.

The simplest form of grouping roses is the arrangement of the dwarf-growing and free-blooming varieties belonging to the hybrid perpetuals, hybrid teas, and Chinas in masses, and these are so attractive over a long period that they should be more liberally employed than is the case at the present time. In the ordinary way these would not be spoken of as groups, but as beds, and the varieties utilised as bedding roses. There is no occasion to dwell upon this point, and so we may pass on to say that a more advanced method of grouping is to plant in association dwarfs and standards. If the latter are selected with due regard to vigour of growth and freedom of flowering, and arranged between three and four feet apart among the dwarfs, groups or beds of the most pleasing character will result. This method of grouping is especially adapted to the requirements of those who are unable to devote otherwise than a limited space to roses.

Distinct from the foregoing are arrangements, which are invariably described as groups, of the vigorous-growing varieties belonging to the several sections, and where the pleasure grounds are of considerable extent such groups may be formed in considerable numbers. In both large and small gardens they will form a distinct and pleasing feature, provided they are proportionate to the area available. For such groups the climbing varieties of several of the hybrid perpetuals and hybrid teas, and strong growers, as Madame Jules Gravereaux, Buttercup, Mrs. Anthony Waterer, Electra, Una, The Wallflower, Conrad F. Meyer, Gruss an Teplitz, and the rugosas are the most suitable. Each group may consist of one or several varieties, but the most satisfactory results are, in the opinion of the present writer, obtained by limiting each group to one variety. If the plants are arranged about two feet apart in beds five feet or so in diameter groups of the most effective character will be obtained in a surprisingly short space of time. These strong growers are very effective when arranged in groups of three or four plants each in shrubbery borders, provided the soil is not permeated with the roots of large trees that are not far distant. The rugosas are perhaps the best able to hold their own where the roots of trees are in strong competition with those of roses for the available food supplies.

In the formation of groups of Wichuraiana roses a somewhat different method has to be adopted. The plants are arranged between two feet and thirty inches apart, and the growths are supported with stout stakes of varying heights. The object is not to form groups of pillars of roses, but groups of roses, hence the necessity for having the stakes of different heights and the adoption of a free style of training. The illustration of an especially attractive group of Dorothy Perkins in the Royal Gardens, Kew, will serve to show the manner in which the growths are supported and trained. It will be seen that each set of shoots is not exclusively trained to a separate support, but that the growths are carried from one to the other of the supports, as was found necessary in the formation of a well-balanced group. Such arrangements are highly attractive in the season of flowering, either at the point of a broad border, as in this case, or on the lawn, and may, therefore, be formed in either position with the full assurance of success.

G.



A TASTEFULLY ARRANGED GROUP OF DOROTHY PERKINS ROSE AT KEW.

HARDY PLANT CHAT.

Solidago Golden Wings.

This golden rod was finely shown by Messrs. Cutbush and Sons this season, and one can see a use for such a flower, although I must confess that I have no special liking for the solidagos. But this tall species is graceful in its way, and for the wild garden it has a raison d'être: while in the very large autumn border a place may be found for it. It makes a handsome growth six or more feet high, and gracefully-habited sprays of yellow, rather fancifully giving it the name of "Golden Wings." Those who are best acquainted with the intricacies of the identification of these solidagos will forgive me for not entering into any consideration of the question as to which species it belongs. It is sufficient to say that, in a limited sphere, it will prove serviceable to many who have large places.

Thalictrum dipterocarpum.

This meadow rue is apparently becoming better known, and the favour with which it is being viewed when exhibited at shows is a token that it is probably destined to find its way into many good gardens. It has been rather well shown of late, and it is certainly a good subject for bloom in the border. Its height, 4ft. to 5ft., renders it excellent for the back row of a small garden border, or for that in front of the rear of a larger one; while the pretty rose-purple inflorescence is well contrasted by the citron-yellow anthers. All these meadow rues are graceful alike in flower and foliage, but they are rarely at their best when in dry soil.

S. Arnott.

WORK FOR THE WEEK.

ORCHIDS.

SEASONABLE NOTES.—The permanent shading on the roof and at the ends of the houses should now be removed so that the whole benefit of the available bright light may be afforded Excepting for odontoglossums and the winter-flowering cypripediums, the roof blinds may be dispensed with altogether. Where canvas blinds are removed from the roof, or where provision is made for their storage under cover on the roof ridge during winter, the first favourable opportunity should be taken to run the blinds down and get them thoroughly dried before storing. The excessive dry summer has not been advantageous to many orchids. With us our plants have made more progress since the rain in August than was the case for many weeks previously. The odontoglossum growths that were in a forward condition previous to June seem to have been retarded, and it is only recently that they have recommenced to grow. This has had the effect of bringing the plants into a more general condition of growth than has been the case for a number of years and the result will be that we shall have the plants flowering in larger quantities together in the spring than usual.

CYPRIPEDIUMS of the winter-flowering section are also backward for the season of the year, and, owing to the amount of shading that has been required, the plants show indications of sappiness, and they have a slightly drawn appearance. It is desirable that the plants should have every encouragment from light and discreet ventilation to assist them to mature their foliage and develop their flowers

AMONG THE MEXICAN LÆLIAS we find growth and flower scape development very irregular. This is particularly the case with plants that were repotted in the spring; some have their flower scapes well advanced, while others are only now developing from the unfolding leaves. It is well to give any backward plants a warmer position if possible, and if they are placed at the warmest end of a cattleya house and in a position within reasonable distance of the roof glass they will derive considerable benefit.

IN THE CATTLEYA HOUSE many of the early growing kinds completed their pseudobulbs rapidly, and it will not surprise me if many growers complain of the appearance of secondary growths. The second growth is not so detrimental when it appears early, but when it commences in September it is no advantage to the plants, as a rule, but very troublesome to the grower, and it is rarely that satisfactory flowers are procured under such circumstances in the early autumn. Careful observation and prompt measures will be necessary to prevent attacks of scale and black thrips; sponging is the best means of keeping both these pests in check; the houses should be fumigated frequently.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

PERPETUAL-FLOWERING CARNATIONS.—These are now in active growth, and must be given regular attention. The flower stems should be loosely tied to the central stake, and disbudded as soon as possible to allow all the strength to concentrate on the terminal bud. Applications of diluted liquid manure may be given at intervals, as well as top-dressings of some approved carnation manure. Ventilation must be given freely to maintain an airy buoyant atmosphere in the house. Even in foggy or frosty weather a little air may be admitted through the top ventilators at night, provided sufficient heat is afforded to maintain an even temperature of 50 degrees Now that dull and cold weather may be expected, the house must of necessity be kept rather drier, consequently red spider is apt to appear, therefore every precaution must be taken to keep it away. One good method at this time of the year, when dampness by syringing must be avoided, is to paint the pipes while warm with liquid sulphur.

CYCLAMEN.—The stock grown in frames will now be showing flowers, and should be removed to a rather higher temperature, but at the same time be afforded ample ventilation whenever possible. Judicious feeding at the present time will repay itself by the excellence of the blooms obtainable later on. Care must be taken to exclude fog from the house, as this is destructive to fully-expanded blooms. The plants require to be kept perfectly clean and free from insect pests. Remove all decaying flowers to encourage the succeeding ones. Seedlings obtained from the early autumn sowing should now be ready for potting off singly into thumb pots; take care not to bury the corm too deeply. A compost similar to the one used for sowing will suit the seedlings at this shift. Place the plants in a light position near the glass in a house where a temperature of 55 degrees may be maintained. Shade must be provided when required, and great benefit will be derived from frequent syringings.

HUMEA ELEGANS. — To cultivate humeas properly, they must be kept in constant growth, and a further shift should be given them now. Five-inch or six-inch pots are quite large enough for this potting, as this will allow for repotting into eight-inch or nine-inch pots in the spring. Through the winter considerable care must be exercised in watering, as humeas require very little at this period. A cool house, from which frost is excluded is a good place in which to grow them.

BLINDS AND SHADING may now be dispensed with, but take care that all are dry before being stored away for the winter.—A. Grubb, Porter's Park Gardens.

HARDY FRUITS.

TRANSPLANTING APPLES. — This may be taken in hand from now onward, and the earlier in the season the work can be performed the less the trees will suffer through the following summer. It is quite safe at the present time to lift apple trees, even if still carrying full leafage, providing reasonable care be taken. We have here repeatedly moved bush and pyramid trees anywhere up to 15 years of age, and possibly older, without a single loss to record. Trees this age have taken on new life after the first year, and produce at the present time the finest and cleanest fruit in the garden through being induced to form new fibres as a consequence of lifting and replanting. Large trees, of course, look formidable, but if the soil is worked carefully away from the roots the task is a fairly light one. Care must be taken to preserve all the fibrous roots possible, the large roots in the case of big trees being left as much as 4ft. in length. The holes for the reception of the trees should be much wider than that actually required, and when replanting use plenty of new loam, lime rubble, and, if possible, some bone-meal. The trees must not be allowed to carry fruit the following summer, and, the most essential point of all, the stem and main branches should be protected from the drying influence of sun and wind by some protecting material, such as bands of hay or straw, these being wound neatly and lightly around them.

CORDON PEARS ON WALLS.—These also may be moved if the borders are known to be in an unhealthy state; but pears generally will suffer or show the effects of lifting more than apples, and should be lifted with as much soil adhering to the roots as possible. This may be accomplished by removing a few trees at one end, and so lifting and removing all, in short shifts, and replanting as the work proceeds. By this mode of cultivation old trees are given new life, and are capable of producing excellent fruit.

PRUNING.—Many of our good varieties of apples cannot under ordinary conditions be induced to fruit to any extent more than once in two years. Belle Pontoise, Mère de Ménage, and many of the American varieties are unsatisfactory in this way. Two very vigorous trees of Mère de Ménage that had been noted for many years not to produce a single fruit in alternate seasons, have been brought into bearing by being winter pruned—that is, pruned with consideration as soon as the fruit is gathered, which is from the middle to the end of September. The two said trees are horizontally trained, with about fourteen leads. Enormous fruits have always been gathered since, and the trees make wonderful growth. Since the experiment has been tried, each year a good crop is obtained, single fruits a pound in weight and upwards having been produced. The experiment is to be followed up with other trees that fruit only in alternate years, with, I hope, the same good effect.—J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

JERUSALEM ARTICHOKES.—The tubers will be sufficiently formed and matured by this to allow of a quantity being lifted for use. The greater part of the crop may be left for a few weeks to continue to develop. When lifting, select the suitable tubers for use, and keep a quantity of medium sized sets for next season's planting.

BROCCOLI.—In many parts of the country the broccoli will not stand the severe frosts at times experienced. The upper portion of the stem of this plant is the first to suffer. By leaning them over to the north and covering their stems with soil well up to the bottom leaves, they do not thaw so rapidly, and a great reduction in the loss of plants will most probably be experienced as compared with those that are not protected.

BRUSSELS SPROUTS.—These are not throwing out their sprouts satisfactorily, but after the rain they will now be growing freely. Have the decayed and some of the coarse leaves removed from the lower part of the stems to permit light and air to reach the sprouts and assist in their development, or they will not harden as they should do. In high and windy situations it is advisable to stake some of the taller plants to keep them erect, so that the sprouts may swell evenly.

CELERY.—Push on the work of earthing-up this crop as far as practical, as severe frosts may now come at any time, and so damage the stems of the plants as to cause them to decay. In carrying out this final moulding-up, make the sides of the rows firm by patting the soil down with a bright spade when it is moist, to throw off the winter's rain.

RHUBARB.—Where a quantity of plants of an early variety have been grown on for the purpose of forcing, they will now be found most useful. The foliage will be well matured, and some crowns may be lifted for placing in the mushroom or other forcing house. Before placing the crowns in heat leave them in the open for exposure for a week or so, as they will then the more rapidly respond to the warmth and grow away freely.

EARLY BORDERS.—These situations will be the first required, and, owing to the weather, are often most difficult to bring into proper condition for early sowing of peas, etc. As soon as the crops of salading and other plants are removed, have these borders manured and dug, leaving the surface of the land rough so that the frost and wind may play upon it to ensure a good seed bed. On light soils a dressing of marl on the top, left to slaken down till the border is required, and then forked in, will be found of great benefit to next season's crop. For old and heavily manured soils I prefer a dressing of marl to one of manure occasionally.

FORCING GROUND.—When the staff is not occupied in important work on the land everything should be put in hand ready for forcing. Have a stock of sweetened manure got ready. Leaves are quite as valuable as manure, and may be collected and stored in sufficient quantities before becoming saturated and decayed. Have all lights and frames repaired in readiness for use.—Charles Flack, Cholmondely Castle Gardens.

BUXTON AND DISTRICT
CHRYSANTHEMUM SHOW.
WEDNESDAY, November 15th, 1911.
For Schedule and List of Prizes, address—
S. SHUFFLEBOTHAM,
Secretary, 12, Eagle Parade, Buxton.

SHEFFIELD CHRYSANTHEMUM
SOCIETY SHOW,
CORN EXCHANGE.

November 16th, 17th, and 18th.
£200 in Prizes.

Schedules, etc., from
C. COOK, City Road, Sheffield.

THE NATIONAL CHRYSANTHEMUM
SOCIETY.
GREAT AUTUMN SHOW
will be held
at the CRYSTAL PALACE,
On NOVEMBER 1st, 2nd, and 3rd, 1911.
Entries close October 25th. Write at once for Schedule and full particulars to
RICHARD A. WITTY, 72, Savernake Road, Gospel Oak, London, N.W.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

North of Scotland Horticultural and Arboricultural Association.

The first meeting of this newly-resuscitated association was held on Saturday evening, the 14th inst., in the Botany Classroom, Aberdeen University. There was a crowded attendance, and Mr. Alexander Robson, of Messrs. Smith and Sons, nurserymen, Aberdeen, was called upon to preside.

In the course of his address, the Chairman congratulated the association on the large attendance, and thought that a good augury for the success of the enterprise on which they had embarked. He referred to the fact that it was now seventeen years since the association ceased its operations, and many old members would recollect what a power the association had been in the horticultural world in Aberdeen and district, how many excellent papers had been read, and almost all published, and had been specially appreciated by those who could not be present at the meetings, and how capital discussions had taken place with regard to meritorious plants, flowers, and vegetables. They had a membership of between 200 and 300. Latterly, however, interesting subjects got rather scarce, and the discussions became confined to a limited number of outstanding members, so it was thought well to give the association a rest. He did not think those who came to that resolution ever contemplated a cessation for seventeen years, and probably if any active gardeners had moved in the matter the association might have been resuscitated years ago. The association had been resuscitated in a constitutional way by the old committee, or as many of the members as were now in this part of the country. It was found they could get as many as 150 members, and that there was the prospect of many others. At the present time there were as many as 165 who had signified their adhesion. They might, he thought, congratulate themselves on the encouragement they had got so far, and look for fresh accessions. It was also satisfactory that they had received promises from several professors and lecturers of Aberdeen University, and others who were in cordial sympathy with the movement. Professor Trail, for instance, in addition to giving the use of his classroom that evening, had promised to give an introductory lecture on "How to Obtain an Improved Race of Cultivated Plants."

The seventeen years since the association had become dormant had been years of activity in the horticultural world. Good garden cultivation had been greatly extended, and indeed it might be said there were now two gardens for every one then, and they had many new races of flowers, and new tastes had developed in connection with horticulture in various directions. There could be now no lack of subjects for the programmes of the association for many years to come. Besides, a new race of enthusiastic horticulturists had come to the front, and they might look forward with confidence to the association occupying the position of influence it held in former times.

Mr. William Reid, interim secretary, said there was every promise of an interesting winter's work, and he hoped the association would go on heartily. A tentative syllabus had been drawn up, including a lecture on How to Obtain an Improved Race of Cultivated Plants, by Dr. Trail, Professor of Botany in Aberdeen University; How to Maintain a Supply of Vegetables all the Year Round; Novelties of the Year in Plants, Fruits, and Vegetables; The Sweet Pea; Meteorological Notes on the Weather; Lessons from the Drought of 1911; The Carnation; Cottage Gardening; and Hardy Spring Flowers.

Mr. William Wyllie, the former treasurer, submitted a statement which showed that the sum at the credit of the association was £10 5s. 6½d.

On the motion of the Chairman, the Earl of Aberdeen was elected patron, while the following were elected hon. members: Dr. Trail, Mr. S. J. Gammell, of Drumtochty; Mr. G. A. Duff, of Hatton; Mr. Leith Hay, of Leith Hall; Mr. Thomas Ogilvie, of Kepplestone; Mr. James Murray, of Glenburnie Park; Mr. J. G. Burnett, of Powis; Mr. J. E. Crombie, of Parkhill; and Mr. Adam Maitland, Rubislaw Den House—the prospective Lord Provost for Aberdeen at the coming municipal election.

Mr. France, F.B.S., proposed the election of Mr. Mackinnon, gardener to the Earl of Aberdeen at Haddo House, as president, and the motion was heartily agreed to. Office-bearers were then appointed, which included the leading gardeners in and around Aberdeen. The Chairman, in answer to a question, stated that there was a library of over 200 volumes in connection with the association, and the committee would draw up a scheme to render the books available in the future.

The usual votes of thanks terminated one of the most delightful and harmonious meetings ever held in Aberdeen.

Horticultural Club.

On Tuesday, the 10th inst., this club opened its winter season by the usual monthly dinner at the Hotel Windsor, Mr. Harry J. Veitch taking the chair. Subsequently a most interesting paper was read by Mr. C. P. Raffill, of the Royal Gardens, Kew, on "Rhododendrons," which evinced at once a wide knowledge and extensive practical acquaintance with this wonderful genus.

The lecturer started with a description of the various sections of the genus and their wide geographical distribution and consequent requirements of different cultural conditions. About 270 species are recognised, of which the large majority are natives of the Himalayas and the extension of that mountain system into the South-West of China. In the earlier days the Himalayas were regarded as the chief home of the genus, but later researches to the North, by Delavay, Henry, and Wilson, have demonstrated, by a great number of new discoveries, that China is really so distinguished, some 144 species being found in the entire mountain range as against about 44 in the Himalayas proper. Curiously enough, despite the continuation of these two habitats, only two species are common to both. Subsequently, by means of a lantern slide of the world, Mr. Raffill showed how the genus was represented by species in North America, Northern Europe, Asia, Tibet, Burma, and India, and passing thence through Ceylon and New Guinea, eventually dwindled into a solitary species in the extreme North of Australia, Java, and the Malay Archipelago presenting many examples of the more tender class.

One species, R. lapponicum, curiously enough, stretched right round the globe on the north. Only two species are indigenous to Central Europe, and none in Africa or South America. The entire genus appears to be alpine; it is most at home in soils consisting of the debris of weatherworn granite wherein there is abundance of silica, mingled with peaty humus, and thoroughly drained by its porous character. Lime is poison to it. From these facts it is easy to deduce the nature of the soil required under cultivation, viz., peat with a liberal admixture of sand in the proportion of one to even three or four plus perfect drainage. Although theHimalayan species are rarely found below 4,000 feet, they are mostly rather tender, and those of Java and Malaya are all so, requiring warm houses. The most recent Chinese introductions are, however, as might be expected from their more northerly origin, hardier, and even quite hardy, and by judicious hybridisation, and even naturally, many of the Indian forms are able to thrive in the open in many places in our warm Western Coast in Cornwall and elsewhere, some magnificent specimens being shown on the screen as growing in the open in some noted Cornish gardens, while views of specimens in the Rhododendron Dell at Kew showed what could be done elsewhere by skilful arrangement of the environment with these and other species. The azalea, which is usually deciduous, and was at one time regarded as distinct from the evergreen rhododendron, owing to a supposed constant difference in the reproductive system, has been subsequently relegated to that genus, and many interesting details were given regarding the cultivation and propagation of the Ghent azaleas, only so called because Belgium has made their culture a speciality.

A just tribute was paid to Sir Joseph Hooker for his introduction by seed of many of the most magnificent forms of rhododendrons shown on the screen, and to Mr. Heal, who, under the auspices of Messrs. Veitch, has effected such wonders in the way of hybridisation among the species introduced by the various explorers. Finally, on the economic side the lecturer alluded to the medicinal properties ascribed in some countries to certain members of the genus in connection with rheumatic affections, and also to the poisonous nature of some species when eaten by cattle.

A very hearty vote of thanks to the lecturer concluded the meeting.

East Anglian Horticultural Club.

There was a large gathering of members at the October meeting of this flourishing club, held at the Boar's Head Hotel, Norwich. The preliminary talk was upon the success of the club in coming out first place at the R.H.S. Fruit Show for apples and pears open to societies in the British Isles, this being the second year in succession that such a distinction has been achieved.

In the special and monthly competitions a good display of flowers, fruits, and vegetables was made, special comment being due to Mr. W. Shoesmith, gardener to F. W. Harmer, Esq., Cringleford, and Mr. W. Laws, gardener to G. E. White, Esq., Eaton, for their meritorious collections of fruit. Mr. Williams, gardener to Louis J. Tillett, Esq., Catton, exhibited a fine cypripedium.

The essay for the evening was given by Mr. A. J. Oakley, grower to Messrs. Hobbies, Lim., Dereham, upon "The Cultivation of the Dahlia." Right ably did the essayist deal with his subject, touching upon all points of culture. The many types of the flower were dealt with, even down to the new collarette section, which has so recently sprung into public favour. At the finish of the paper discussion was invited and keenly taken up. Thanks were accorded to Messrs. Hobbies, Lim., for the splendid collection of dahlias sent to illustrate the subject. Many of these were quite new kinds of the firm's own raising.

Among the specialities of the evening were a dish of fine fresh raspberries from Mr. W. Shoesmith; splendid red currants from Mr. W. Laws; and an Up-to-date potato tuber from Mr. T. Notley, Catton Hall Gardens, which scaled 2lb. 15oz.

Reading Gardeners' Association.

The second fortnightly meeting of the present session of the Reading Gardeners' Association was held on Monday, the 2nd inst., in the Abbey Hall.

Mr. F. Townsend, who presided over a large gathering of members, announced that the arrangements for the forthcoming exhibition in the Corn Exchange on November 8 were being pushed forward, and that tickets were now ready for members, whom he urged to make special efforts to ensure another successful show.

The speaker for the evening was Mr. H. Goodger, head gardener to Mrs. Collins, Stoneham House, Tilehurst, and his subject was "Melon Cultivation." This was Mr. Goodger's maiden effort as a lecturer, and his success will encourage him to appear on the platform again. Mr. Goodger dealt with the cultivation of this luscious fruit in the most practical manner, and gave the fullest information respecting the style of house to be employed, temperature, seed sowing, transplanting, mounding, watering, stopping, fertilising, supporting and ripening the fruit. He also touched upon the somewhat debatable question of shading melons. The insect and fungoid pests to which the plants are subject were also fully dealt with and remedies recommended. The lecturer stated that he relied chiefly on four varieties, viz., Sutton's Ringleader, Superlative, Hero of Lockinge, and Eastnor Castle. At the close of his remarks Mr. Goodger received many congratulations on his lecture.

A number of exhibits were staged, and three certificates were awarded, viz., to Mr. F. Townsend, head gardener to the vice-president, for three fine bunches of grapes (Muscat of Alexandria), to Mr. H. Goodger (the lecturer) for a tray containing three dozen well-grown Ailsa Craig onions, and Mr. J. H. Shipley, head gardener to Mr. F. W. Nicholson, the Old Rectory, Shiplake, for what may be described as a unique exhibit of Leonitis Leonurus (Lion's tail). The latter which proved of great interest, is a highly ornamental greenhouse shrub, a native of South Africa, and is not often seen so well grown and flowered as in the specimens staged.

Mr. H. C. Loader, head gardener to Mr. M. H. F. Sutton, Erlegh Park, showed some beautiful late asters, mammoth shell-pink, which were much admired, and Mr. F. Toovey, The Gardens, Leighton Park, staged a dish of very large Blenheim Orange apples. The two latter exhibits were not entered for certificates.

Bristol Gardeners' Association.

A meeting of the above society was held on October 12, at St. John's Parish Rooms, Dr. Shingleton Smith presided over a large attendance. Mr. Drew, representative of the Reading Society, gave a lecture on "Prevention of Insect and Fungoid Pests of Fruit Trees."

The lecturer said it was generally recognised that pests and diseases were more troublesome now than formerly. He believed this had been brought about by errors of cultivation, viz., the indiscriminate use of the dwarfing stock. The remedy for this was the careful selection of healthy stocks, and in order to obtain a more uniform growth, buds and grafts should only be taken from young healthy trees. Another reason for this prevalence of pests, the lecturer said, was that large areas had been planted; disease was more prevalent where there was a large aggregation of trees. To mitigate this evil Mr. Drew advised the making of large air spaces in plantations. Digging and cropping beneath fruit trees the lecturer condemned, as aiding the spread of disease, also the want of recognition of the serious nature of pests. He advised applying remedial measures in time.

For a collection of vegetables Messrs. Binfield, Springham, and Young won in the order given.

For a cypripedium Mr. Woodward had four points, and Mr. Springham three points.

One new member was elected.

Parkstone Gardeners' Association.

On Thursday, October 12, an exhibition of apples and pears was held by the members at their fortnightly meeting. About one hundred dishes were staged, and represented some of the best varieties, in excellent condition. Cox's Orange Pippin was the principal dessert variety staged; it has done remarkably well in Dorsetshire, as in other counties, this year. Lane's Prince Albert, Gascoyne's Scarlet, and Warner's King were also well shown, and Doyenne du Comice and Pitmaston Duchess pear.

For two dishes of apples, one dessert and one kitchen, Mr. May was the winner with Kerry Pippin and Lane's Prince Albert, the last-named being exceptionally fine. Mr. Selway was second with Cox's Orange Pippin and Bramley's Seedling, and Mr. Cox, gardener to G. S. Duberley, Esq., third with Cox's Orange Pippin and Gascoyne's Scarlet. For one dish of dessert apples first honours went to Mr. House, gardener to J. J. Allen, Esq., who had a grand dish of Cox's Orange Pippin. Mr. Groves, gardener to General Poppin, was second with Beauty of Hants, and Mr. May third with Cox's Orange Pippin.

Mr. Gould, gardener to the president (Dr. Crallen) staged a magnificent dish of Pitmaston Duchess pears, and won first honours. With the same variety Mr. Cox was placed second, Mr. Pullman being third with a beautiful dish of Doyenne du Comice.

Mr. Cox staged twenty dishes of apples and pears not for competition, for which a first-class certificate was awarded.

The soil in the district is rather light and sandy, and it is quite remarkable that such fine fruits should have been grown in it this year. About fifty members were present at the exhibition and meeting.

Birmingham Gardeners' Association.

The opening meeting of the autumn session was attended by a good muster of the members, with Mr. C. H. Herbert (the vice-chairman) presiding. Several new members were enrolled. Much interest centred in the subject of the evening, viz., "Mendel and Mendelism," by Mr. Walter E. Collinge, M.Sc., F.L.S., F.E.S. After tendering an apology for introducing to his hearers the somewhat abstruse but absorbing subject "Mendelism" and in which there is a growing interest, also giving a lengthened review of the life of Gregor Johann Mendel, who was born in 1822, and died in 1884, Mr. Collinge drew attention to the strange fact that, although the results of his experiments were published in 1856, they passed unheeded until 1881, when they only received passing notice by Focke; and it was not until 1900 that they were made known to the scientific world.

Mr. Collinge gave an account of the task that Mendel set before him, viz., to obtain some clear conception of the manner in which the definite and fixed varieties known to occur within a species were related to one another. In the common pea (Pisum sativum) he found a normally self-fertilising plant, unlikely to be crossed by insects, and at the same time one that possessed definite fixed varieties breeding true to the type. After entering with some detail into the experiments and their results, which were exemplified by a series of diagrammatic demonstrations. Mr. Collinge reviewed the work that had been done since, especially that of Professor Bateson, Professor Punnett, Professor Biffen, Mr. Hurst, and others. The possibilities of science and its application to plant and animal breeding are scarcely realisable. What at the present moment seems most desirable is that the various results that have been obtained by the students of Mendelism should be put forth in such a style that they will excite the interest of the farmer, fruit grower, stock breeder, and horticulturist.

There is no doubt but that our agricultural colleges might do more in the way of practical demonstrations than they had yet attempted; such demonstrations would show the farmer and horticulturist that science and practice were going hand in hand, and at the same time would stimulate their interest in the advancement that is taking place. What the ultimate effect of Mendel's views will be upon animal and plant breeding it is difficult to say; there yet lies a vast field for research and experiment which, in the light of results already obtained, would seem to contain undreamt of possibilities. We have obtained some glimpses of the importance of these in Professor Biffen's work on cereals, but further work will only add to the importance of the possibilities and widen the outlook.

In the interesting discussion which followed, and in which Mr. C. H. Herbert submitted a few remarks on Primula sinensis, of which genus he is a well-known specialist; Mr. A. B. Burn adverted to the carnation; Mr. J. Palmer to the sweet pea; and Mr. J. Webb to the fugitive colouration in certain varieties of aubrietias. Mr. Collinge, in responding, remarked it afforded him much gratification that his tentative deductions had evoked so great an interest amongst his hearers.

The Beckenham Horticultural Society.

This society commenced its lectures for the session 1911-12 on Friday, the 13th inst., at the Church House, Councillor C. E. Baker, chairman of the Beckenham Urban District Council, presiding, when Mr. Montague Allwood, of Allwood Brothers, Haywards Heath, Sussex, discoursed on the "Perpetual Carnation." There was a crowded audience. To those about to procure stock it was recommended to buy good flowering plants instead of small plants, it being approximately cheaper and better to do so. Pure sand as a medium for propagating is superior to a mixture of soils. A temperature of 40 to 45 deg. with a bottom heat of 5 to 10 deg. above this, would be suitable. It was advised not to strike carnations in autumn, but at such a time that the recently struck plants had the advantage of increasing length of daylight. Varieties wear out, fifteen years would see the end of their usefulness from a commercial point of view. Young plants should be stopped at the fifth or sixth joint, not merely pulling out the incipient leaves at the top, but by removing one or two sets of full-grown leaves. All the shoots on any given plant should not be stopped simultaneously, but done at intervals, so that successional blooming may result. Stopping should be discontinued by the second week in July, a month earlier was advised for the English varieties, of which Britannia is one. Where desired, the young plants could be planted out at the end of April (if prepared for it) a foot apart, and lifted in early July. The plants should be housed in August and September. The change from outside to inside must be made as gradual as possible, and the houses should at no time be entirely shut up.

The lecturer has somewhat modified his practice as to potting, and does not now pot so firmly as in the past, not using a rammer, but still the soil must be firmly put into the pots. Sea sand was advised where procurable, but leaf-mould not admissable; some dry cow manure, or, failing that, horse manure, one part of manure to four parts loam.

For rust, etc., a dry application of equal parts sulphur and air-slaked lime blown over the plants the lecturer considered better than liquid preparations. Flowers should be cut when three parts developed and put in water for 24 hours. One ounce of salt to a gallon of water as an antidote for red spider, to be put on with force.

A very hearty vote of thanks was accorded Mr. Allwood for his splendid lecture. On behalf of Miss Bullivant, Eden Park, the chairman presented to the society the set of books by Mr. A. D. Hall, of Rothamstead, viz., "The Soil," "Fertilisers and Manures," and "The Feeding of Crops and Stock." These are much appreciated. Mr. Piper had on show a nice collection of fruit—apples, pears, and grapes—and a special certificate was awarded; and Mr. Fane secured a certificate for a good example of Vanda cærulea.

HORTICULTURE AND OYSTERS AT COLCHESTER.

Although there is no immediate association between horticulture and oysters, there was a large gathering of horticulturists at the Colchester Oyster Feast on the 12th inst. Their presence in such large numbers may be explained by the fact that Colchester has for its Mayor this year Mr. Frank Cant, who not only enjoys a high reputation as a rosarian, but is held in the highest esteem by horticulturists of all classes who have the pleasure of his acquaintance. Certainly none of the horticulturists had less pleasure in being present at this ancient civic function than had any of the four hundred or more guests who had assembled in the Moot Hall to do honour to Colchester's Mayor and justice to the succulent bivalves which, with roses, have contributed to the fame the town has so many years enjoyed.

For a long series of years the Colchester Oyster Feast has been remarkable for the number of distinguished men present, and this, by common consent, was the most brilliant of these feasts, both as regards the high distinction enjoyed by a large proportion of those present, and the success achieved by the Mayor as host. The Chinese Ambassador had accepted an invitation to be present, but at the eleventh hour was unable to fulfil his engagement; but the Lord Mayor and Sheriffs of London were present, with the distinguished scientist, Sir William Ramsay, and a whole host of celebrities in various walks of life. Among the horticulturists present we noticed Sir Jeremiah Colman, Bart, Sir Albert Rollit, Mr. H. B. May, V.M.H., Mr. J. Hudson, V.M.H., who, as is so well known, occupy prominent positions in the management of the Royal Horticultural Society and the Royal International Horticultural Exhibition, 1912; the Rev. J. H. Pemberton, president; Mr. E. Mawley, V.M.H., hon. secretary; Mr. G. W. Cook, treasurer; the Rev. Page Roberts, Mr. C. E. Shea, Mr. James Brown, Mr. O. G. Orpen, and Mr. George Gordon, V.M.H., vice-presidents; and Mr. H. S. Bartleet, Mr. G. Burch, Mr. R. F. Felton, Mr. G. A. Hammond, Mr. W. R. Hammond, Mr. L. Pawle, Mr. E. J. Holland, Mr. George Paul, V.M.H., Rev. R. Powley, Mr. W. D. Prior, Rev. J. B. Shackle, Mr. W. Tayler, Mr. A. Turner, Dr. A. H. Williams, and Mr. C. C. Williamson, members of the council, of the National Rose Society; Mr. W. Andrews, Mr. W. W. Bunting, Mr. T. Bunting, Mr. S. Cant, Dr. Pallett, and Mr. W. Messenger.

The Moot Hall, in which the function was held, was, as befitted the occasion, richly decorated with roses. The display of these fragrant flowers was, indeed, such as to suggest an autumn rose show rather than a gastronomic feast; and also to contribute materially to the enjoyment of the guests, and especially to the contingent of rosarians. To the right and left of the handsome mace which reclined on the upper table in front of the Mayor, were vases of Madame Melanie Soupert, the soft yellow hue of the blooms of this fine rose being in complete harmony with the bright colouring of the Mayor's insignia of office. The remainder of the table was decorated with vases of well-developed blooms of Madame Abel Chatenay and Molly Sharman Crawford, associated with the blooms of the former were sprays of the foliage of Rosa rubrifolia, and with those of the latter buds of Irish Elegance. From a floral point of view the vases of roses, extending the whole length of the hall, were highly effective, but it is an open question whether they were not rather too numerous. The cross tables were tastefully decorated with small vases containing some six or seven blooms each of one variety, and interspersed with these were a few large vases of blooms in mixed colours. Need it be said the roses were of Colchester growth: but it should be mentioned that their arrangement was carried out by Colchester ladies, who had the help of Mr. R. F. Felton. Associated with the roses on the Mayor's table were numerous silver challenge cups and other trophies for roses which were contributed by Mr. O. G. Orpen, Messrs. Frank Cant and Co., and Messrs. D. Prior and Sons. These were of interest as evidence of the diversity of taste shown by the various societies in the provision of rose trophies, and the success that has been achieved by the rosarians within the district of which Colchester is the centre in the winning of prizes offered for their favourite flowers.

Intellectually the feast was of a high order, and the various speeches that were made in connection with the toast list received close attention throughout the two hours and a half over which they extended. The popularity which the Mayor of Colchester enjoys in his native town was fully exemplified by the enthusiastic reception accorded him when he rose to propose the first of the loyal toasts, namely, that of "The King," and also when he submitted "The Chinese Minister" in a speech that proved one of the most important of the oratorical efforts of the gathering. "Horticulture and Science" had a place in the programme, and to this Sir Jeremiah Colman, Bart., and Sir William Ramsay responded in a manner that gave evident pleasure to their audience. The Mayor's health was proposed by the Lord Mayor, who testified in warm terms to the splendid services Mr. Frank Cant had rendered in the discharge of his duties during the year, and the expressions of approval of the Lord Mayor's remarks afforded ample evidence that he was voicing the opinions of those residents within the borough who had the good fortune to be present.

The comfort of the large number of guests who travelled from London was greatly increased by the forethought of the Great Eastern Railway Company in providing a special train, consisting of splendidly-fitted saloons, for their conveyance to and from Colchester.

The 29th annual grand chrysanthemum show of the Brighton and Sussex Horticultural Society will be held at the Dome and Corn Exchange on October 31 and November 1. Entries close October 25. The secretary is Mr. A. J. Gaston, 170, Springfield Road.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

ADDRESS.—J. B., Barcombe: We have forwarded the letter, adding the address, as requested.

POLYGONUM BALDSCHUANICUM. — S. P. R., Kensington: This fine climber does not need pruning. When first planted its growths should be carefully tied out over the object to be covered, and in subsequent years a little training and thinning, as necessary, are all that is needed. Once established and given plenty of room to ramble P. Baldschuanicum can take good care of itself, and will flower freely in all but the very worst of positions.

ORCHIDS.—D. B., Manchester: Very many thanks for your appreciative letter: we will do as you wish.

MACARTNEY ROSE.—G. L. L., Bexley: The Macartney rose (Rosa bracteata) is a beautiful Chinese species, practically evergreen, but it is rather tender, and therefore should be planted in a sunny position against a south fence or wall. It is summer flowering, and gives large white fragrant flowers. The best-known form is R. bracteata alba simplex, in which the white petals surround a very large and conspicuous cluster of bright yellow stamens.

CUT-LEAVED ALDER. — N. E. S., Newark: The cut-leaved alder (Alnus glutinosa laciniata), is a very graceful tree, and one we strongly recommend you to plant near the lake-side. It is very hardy, and a good grower, and, besides being an elegant subject, it may serve as a wind break for tender trees, though it looks best when planted so that each tree can develop its beauty without the too close attention of neighbours. There is a golden-leaved form of the type, and also a variegated form of the oak-leaved alder; the former is especially ornamental.

INTERNATIONAL HORTICULTURAL EXHIBITION SCHEDULE.—C. P., Truro: The schedule of prizes for the Royal International Horticultural Exhibition to be held at Chelsea from May 22 to May 30, 1912, inclusive, may be obtained on application to Mr. T. Geoffrey Henslow, 7, Victoria Street, Westminster, S.W.

POND WEEDS.—C. R., Devon: We do not know of any special method of clearing the ponds and lakes of such water weeds as the potamagetons. A regular system of cleaning would keep the weeds in check, but probably the water supply would continue to bring down weed seeds. If any of our readers can suggest special measures for keeping lakes and ponds clear of water weeds we shall be glad if they will write us on the subject.

CLEMATIS, ETC.—S. P. R., Kensington. Shorten the growth of the Jackmanni clematis to half its length, and next year train the strongest shoots over the fence. Subsequently keep the growths moderately thinned out, cutting the unnecessary stems right back, so as to induce basal growth. Clematis Henryi is a fine variety of the lanuginosa section, and it bears a profusion of large creamy-white flowers, it would succeed on a wall or fence with a south-west exposure. A passion-flower would not be a success in the shady corner, the selection for such a spot is limited, especially as you rule the ampelopsis and ivies out of order. Aristolochia sipho and Vitis striata would do if the position is a warm one, but we could advise you better if we had further information concerning the site.

SPOTTED APPLES.—L. V. B., Henbury: The apples show clear signs of attack from Bitter Rot or Bitter Pit, a fungus to which we referred in a quite recent issue. Spraying and good cultivation will secure clean fruits.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

M. L., Sidmouth.—Berberis Darwini.

D. N., Nuneaton.—Plumbago Larpentæ.

D. B. T., Dover.—A small late flower of Rudbeckia speciosa.

C. O., Gloucester. — Campanula latifolia and a variety of Eleagnus pungens.

W. F. R., Fife.—1 and 3, growth and fruit of Arauja sericofera; 2, Cassia lævigata.

C. R., Devon.—The water weeds are Potamagetons, possibly forms of P. pusillus, but very difficult to determine from small specimens.

C. F. M., Oswestry.—1, Callicarpa purpurea; 2, Calceolaria Burbidgei; 3, Pelargonium Clorinda; 4, Cypripedium insigne Sanderæ.

F. E. G., Harrogate.—1, Euonymus radicans; 2, Polypodium aureum; 3, Begonia fuchsioides; 4, Eucalyptus citriodora; 5, Cestrum elegans; 6, Dicksonia antarctica.

NAMES OF FRUIT.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, Gardeners' Magazine, as advised in the notice at the head of "Answers to Correspondents."

J. F., Weston-super-Mare.—Warner's King.

W. W., Hexham.—1, Bramley's Seedling; 2, Newton Wonder.

F. T. K., Bedford.—Bismarck apple; the pear is Doyenne du Comice.

B. N. J., Harpenden.—1, Royal Jubilee; 2, Hoary Morning; 3, Lady Henniker.

P. S., Swindon.—1, Hollandbury; 2, Peasgood's Nonsuch; 3, Golden Noble; 4, Ecklinville.

F. B. C., Chertsey.—1, Louise Bonne of Jersey; 2, Beurre Bosc; 3, Durondeau; 4, Beurre Diel; not recognised.

CATALOGUES RECEIVED.

R. H. BATH, LIM., WISBECH.—The Wisbech firm grows bulbs extensively, and so their catalogue is specially interesting because the bulbs offered have been chiefly produced at the Floral Farm.

J. JEFFERIES AND SON, CIRENCESTER.—A good general list devoted entirely to bulbs, and including a wide range of kinds and varieties.

WM. BAYLOR HARTLAND AND SONS, PATRICK STREET, CORK.—The Ard Cairn daffodils and tulips are well known, and in the catalogue before us one is surprised to find how many varieties of these flowers have been raised by Mr. Hartland.

YOKOHAMA NURSERY COMPANY, LIM., YOKOHAMA, JAPAN.—This vastly interesting catalogue is fully illustrated, and contains some coloured plates. The leading subjects offered are liliums, dwarf trees, fern balls, Cycas revoluta, chrysanthemums, paeonies, bamboos, and ivies. The London office is Craven House, Kingsway.

WM. DEAL, BROOKLANDS KELVEDON.—This freely-illustrated list is chiefly devoted to sweet peas, and especial prominence is given to such home-raised varieties as Juliet, Scarlet Monarch, Bertrand Deal, Empress, and Colleen.

JAMES MURRAY AND SONS, DEPTFORD, S.E.—When planting beds or borders of bulbs it is very important to know what varieties are early, mid-season, or late flowering and which flower simultaneously. Such information is given in Messrs. Murray's catalogue in connection with hyacinths and tulips.

G. COOLING AND SONS, BATH.—As in previous years the Bath firm make a special feature of collections of bulbs.

MARKETS.

FRIDAY, November 17.—Bolton Chrysanthemum Show; two days.

MONDAY, November 20.—National Chrysanthemum Society; Floral Committee at Essex Hall, 3 p.m.; General Committee at Carr's Restaurant, 7 o'clock.

TUESDAY, November 21.—Royal Horticultural Society; committees meet at 12 o'clock; lecture at 3 p.m. on "The 1912 International Horticultural Exhibition," by Mr. Edward White; Scientific Committee at 4 o'clock.

FRIDAY, November 24.—Aberdeen Chrysanthemum Show; two days.

WEDNESDAY, November 29.—Irish Gardeners' Association.

THURSDAY, November 30.—Royal Horticultural Society's Colonial Fruit Show; three days.
Manchester and North of England Orchid Society.

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price **10/6.** Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

N.B.—Please register orders early for Dendrobium Nobile, thick-bulbed variety; Dendrobium Jamesianum, Dendrobium Bensoni, Renanthera imschootiana, Vanda Cœrulea Lushai Hill variety, dark blue type; Cypripedium spicerianums of five and six growths, as these are scarce and expensive collecting.

NOTES OF OBSERVATION.

Sternbergia lutea.—This is now most brilliant in the alpine garden, planted in a good depth of sandy soil, and near a large boulder which shelters it from the wind. It is quite at home here, and attracts attention at once, the golden-yellow flowers being both large and bright. Planted in clumps, the sternbergia is unusually effective at this season.—W. A. Cook.

Zonal Pelargonium Salmon Paul Crampel.—This comparatively new variety has gained many admirers this season, and is now widely distributed. Except in the colour of the blossoms it is a counterpart of the well-known Paul Crampel, and, like it, has done remarkably well during the season of 1911. In the wet weather of the preceding year the typical Paul Crampel was equally good.—W. T.

Helenium Riverton Gem.—This has with me proved itself to be one of the best of dry weather plants, while the blossoms have resisted the sun well. What is more, with the wealth of yellow-flowered composites in bloom at the same time the distinct colour of this helenium causes it to stand out markedly from its associates. Notwithstanding that my plant is in a sloping border facing due south, and consequently exposed to the burning sun day after day, it retained its foliage well. The last week in July the earliest blooms opened, and at a corresponding period in September it was still very beautiful. The warm terra-cotta hue of the blossoms was much admired, while a marked feature is the change that takes place afterwards, as they become more of an old-fashioned wallflower tint.—W. T.

Protecting Rock Plants.—There are many choice plants which have a dislike to the continued wet and dampness of late autumn and winter, therefore it is necessary to afford them some protection. This should be provided by placing sheets of glass overhead to prevent the rain from reaching them. There must be nothing in the shape of coddling, unless the subject is a tender one. The androsaces suffer greatly from excessive moisture, and if not protected, they frequently damp off. Onosma taurica is another plant which must be kept fairly dry at the collar. Eritrichium nanum is an exceedingly difficult subject to deal with, and will certainly rot if not kept dry during its resting period, which usually extends from October until February. Other plants requiring the same treatment are soldanellas, Saxifraga Boydi and S. Burseriana, and opuntias. Much depends on the locality, as some gardens suffer more from dampness than others, and while in dry atmospheres plants will survive the winter totally unprotected, yet, where dampness prevails, they die unless looked after.—E. C. Pooley, Gnaton Gardens.

LOUGHBOROUGH LEICESTERSHIRE
London Office 122 VICTORIA St. S.W.

MODERN GLASSHOUSES

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Floral Form.

In the process of evolution flowers have assumed an infinite variety of forms, tints, and modes of arrangement, all of which have for their object the eventual fertilisation of the associated seed to the best advantage. This advantage is gained in the great majority of cases by the increase of conspicuousness and consequent attraction of the insect world as conveyors of the pollen to the ovary or incipient seed. The flowers, as popularly recognised, are simply modified leaves, which, as a rule, are transformed into petals, which are so associated with the reproductive parts as to perform this attractive office, which done, they fade and wither, leaving the now fertilised seed to perfect itself by virtue of the conjunction effected, and to be scattered or wafted abroad by the thousand and one contrivances subsequently developed in connection with the seed vessel. Such plants as are wind fertilised, that is, such as are independent of insect aid, their pollen being borne from male flower to female flower by the friendly breeze, bear as a consequence comparatively inconspicuous flowers. To attain a conspicuous character, flowers have been evolved in many different ways, some have assumed a considerable size individually, and others have attained that object by massing together their blooms of smaller dimensions. Primarily, there is little doubt, flowers were green or greenish and small in size, but in time variation and insect selection brought about other tints, the brightness of which was sure to attract greater numbers of insects, and thus enjoy a better chance of reproduction, while their progeny under the principle of inheritance, plus that of successive variation, constantly progressed, until at length the world was filled, as it now is, with an inexhaustible wealth of floral beauty and diversity. When, however, man came in as an intelligent selective factor on other lines than purely natural ones, this progression advanced by leaps and bounds, and in a few generations changes can be effected which, unassisted by man, would take æons to produce, or, more probably still, especially where natural lines of selection are contravened, as in the case of double or sterile flowers, would never have come about at all. Man's floral selection, as a rule, cares little for the laws which govern Nature's plans for the survival of the race, the object is increase of what he considers to be beautiful and decorative, and he is perfectly satisfied if, by a fortunate "sport," or a successful cross, he obtains results to his taste which can only be propagated asexually by cuttings, budding, or grafting. The normal simplicity of form, however much it may appeal to him æsthetically, is not good enough, and in his endeavours to improve it, it often happens that he lays down hard and fast lines which determine what he terms "form," and ruthlesly destroys all seedlings which depart from his standard. There is no doubt that, thanks to this restriction, an infinite number of possibilities have been nipped in the bud, as an instance of which we may quote the well-known example of the cactus dahlia, which, had it not accidentally been imported from Mexico, instead of appearing as a seedling on this side, would have undoubtedly shared the fate of myriads of sportive seedlings of the old standard type. We have now a host of divergent types, of which the old dahlia growers never dreamt. The new "Collarette" section, to wit, attracts great attention just now, although as yet very imperfect, since breeders fully recognise its incipient beauty and well know that selection will eliminate its defects in time. To the expert judge of flowers, good "form" is one of the greatest essentials, and this must apply not merely to the flower but also to its habit, i.e., bearing on the plant itself. Many a well-formed flower fails to display itself to the best advantage by having a drooping habit or short stalk which tends to hide it beneath the foliage. It may also be handicapped by a slow development, so that, by the time all its petals are fully opened, the first ones may be fading. Some flowers, like many of the carnations, have been so fed and pampered and forced away from normal development, that the calyx bursts, and instead of a round, symmetrical, well-balanced flower, the proper "form" of the blossom, a confused mass of irregular petals offends the eye, and disqualifies the bloom. So it is with regard to colours, where good "form" involves purity and regularity of distribution. Here possibly it is with the "auricula" cult that the judges are more strict in this direction, so strict, indeed, that it is often difficult for the outsider to detect disqualifying defects or to properly appreciate the "advance" which the expert declares to have been made. Every flower of note, indeed, has its "form" or "forms" demanded by good judges, and on salutary lines; but, as we have indicated, it occasionally happens that departures from these standards of perfection, slight and merely indicative, perhaps, at first, have eventually proved of great value, and shown themselves to be the "sportive" progenitors of strains that are equally remarkable for their distinctness and beauty.

Mr. W. G. LOBJOIT.

Mr. William G. Lobjoit, whose portrait we have the pleasure of giving in this issue, is the head of a firm of market growers with headquarters at Heston, near Hounslow, and he has, through a long series of years, filled that position in such manner as to obtain the esteem of his neighbourhood, and the respect of those who at Covent Garden and elsewhere have business relations with him. Mr. Lobjoit has the good fortune to possess a keen intellect, and as one result thereof, he holds advanced views, both with regard to cultural matters and the importance of meeting market requirements in accordance with modern methods. That his firm, as the result of his enterprise, has achieved a high degree of success, goes without saying. But it may be mentioned as a matter of some interest, as evidence of the advanced views held by Mr. Lobjoit and of his remarkable enterprise, that he was one of the first of those engaged in commercial horticulture to adopt mechanical traction for carrying goods to market. This method of traction is still adhered to, and it must be a great advantage as compared with horse traction where, as in this case, enormous quantities of produce have to be marketed as expeditiously as possible. While taking the keenest interest in the exacting business in which he is engaged, Mr. Lobjoit does not allow it to absorb the whole of his attention, as evidenced by the number of positions he occupies with so much honour to himself and advantage to the several bodies. He is a J.P. for Middlesex, a honorary correspondent to the Board of Agriculture, vice-president of the Market Gardeners, Nurserymen, and Farmers' Association, and is chairman of the Heston-Isleworth Urban District Council. At the general election two years ago Mr. Lobjoit contested the seat for the Brentford Division of Middlesex in the Liberal interest, and, although he was unsuccessful, he was strongly supported, and, by reason of his commanding abilities, he won golden opinions from his friends, and excited the admiration from not a few of those who hold views differing from his own.

Important to Secretaries of Horticultural Societies. — The edition of the "Gardening Year Book" for 1912 is in an advanced stage of preparation, and secretaries of botanical and horticultural societies and gardeners' associations are earnestly requested to return the notices properly corrected which they have received, with as little delay as possible, so that any changes which have been made in the names or addresses of the secretaries may be duly recorded in the list of Horticultural and Botanical Societies of the United Kingdom We shall also be glad to receive from our readers notification of any such changes as have come under their notice.

Royal International Horticultural Exhibition, 1912.—We are informed by the Directors of the Royal International Horticultural Exhibition that, in consideration of numerous requests from representatives of the horticultural world, they have decided to provide special facilities for professional gardeners, and also to make reductions in the charges to the general public. The prices originally fixed for the eight days of the Exhibition are as follows: First day, two guineas; second day, one guinea; third day, 10s.; fourth day, 5s.; fifth day, 2s. 6d.; and on all subsequent days, 1s. The following charges for admission have now been arranged: Until 5 p.m. the charges will on the first four days be as originally fixed, but after that hour they will be as follows: First day, one guinea; second day, 10s.; third day, 5s.; fourth day, 2s. 6d.; on the fifth day, the charge throughout the day will be 2s. 6d.; and on all subsequent days the admission fee will be 1s. The special rates for professional gardeners throughout each day are: Second day, 5s.; third day, 2s. 6d.; fourth and all subsequent days, 1s. The Directors inform us that they have retained the original prices for admission during the greater part of each day, chiefly on account of the limited space at their disposal. The actual size of the ground is 21 acres, but at least seven acres are occupied by trees, shrubs, etc., which leaves only 14 acres for tents, exhibits, offices, etc., etc. Applications for space have naturally been very numerous, and ground has to be allotted for paths, promenades, and so forth. It must also, they observe, be remembered that, apart from the visitors themselves, there will be a large number—say three thousand—of officials and servants, including jurymen, exhibitors, attendants, etc. It is gratifying to be able to announce that in the floricultural section of the exhibition British growers have made a very ready response to the invitations addressed to them. Foreign floriculturists from most parts of the world are also applying for exhibition space, so that the international character of the show will be well maintained.

Carnation Lady Alington. — Having from the time this carnation was first introduced to public notice held a high opinion of its merits, we have watched with much interest its rapid progress in public favour. It has therefore given us much pleasure to receive from Messrs. Stuart Low and Co., of the Bush Hill Park Nurseries, Enfield, a gathering of finely developed blooms. Lady Alington belongs to the perpetual-flowering section, and has the merit of possessing a robust constitution and also of flowering freely. The flowers are large, full, and of superb form, and the colour is an exquisitely beautiful shade of rose-salmon. Not the least of its good qualities is its delightful fragrance, which as we write pervades our study.

Guides for Kew Gardens.—During the past few days there has been in "The Times" a discussion of the question of providing guides for the visitors to the museums in the Metropolis. In the course of the discussion, Lord Sudeley, in decribing what had been done in the matter at the British Museum and the Imperial Institute, suggested that a guide might with advantage be provided at the Royal Gardens, Kew. In support thereof, he observed: "Kew Gardens it is impossible to visit without longing for the power of obtaining guidance and special information, which for the ordinary visitor is tedious and tiresome to obtain by continual reference to a plan or guide-book printed in small type. With reference to this suggestion, "The Times" of Tuesday last states: "Our Richmond Correspondent had a conversation yesterday with Lieutenant-Colonel Prain, Director of Kew Gardens, on the subject of Lord Sudeley's letter in 'The Times' advocating the employment of guides in museums in continuation of the experiment at the British Museum, and the extension of the system to Kew Gardens. Lieutenant-Colonel Prain said he did not think there was any great necessity for such guides, for at the principal entrances to the gardens notices were posted indicating to visitors what were the sections most interesting and most worthy of a visit. The stranger who had only a limited time at his disposal could see at a glance what were the features of the gardens for the time being. All he had to do was to purchase a key plan, price twopence, and compare the letter and figure on the notice with the map. The Government would not agree to further grants from the Treasury for the purpose of paying guides. The expense would not be justified. Kew Gardens were entirely dependent on the weather for the number of visitors, and while for one or two months of the year there would be plenty for professional guides to do, for the greater period they would be practically idle."

Dahlia Brentwood Yellow.—Since this fine decorative dahlia was introduced to public notice, in the summer of 1910, it has steadily gained in popularity, and is now regarded by those who have had opportunities for seeing it in the garden during the past summer as the best of all the varieties in its class that produces yellow flowers. In the spring of the current year we gave an illustration of a bloom for the purpose of calling the attention of our readers to it, and at the first of the two meetings held by the Royal Horticultural Society during the current month an Award of Merit was made in its favour by the Royal Horticultural Society. Now we have before us a box of blooms kindly sent us by Mr. J. T. West, of Brentwood, by whom it was raised, for the purpose of showing us its freedom of flowering thus late in the year. The blooms are borne on stiff, erect stems, twelve inches or so in length, but those sent us by Mr. West have been cut with portions of the branches, which is an advantage, inasmuch as it shows the manner of flowering characteristic of the variety. The buds are mostly produced in triplets in various stages of development, and the partly-expanded flowers and the buds produce a delightful effect rising among the masses of large rich yellow blooms. Basing our opinion upon the plants growing in our own garden, we regard Brentwood Yellow as a capital companion to Kaiserin Augusta Victoria, which has proved an ideal bedding dahlia.

Future of the Crystal Palace.—On Monday a conference of public bodies was held at the Mansion House to consider the question of the acquisition of the Crystal Palace and grounds for the use of the public. There was a large attendance of delegates from the London municipal authorities and societies and associations. The Lord Mayor, who presided, submitted a resolution declaring that the Crystal Palace and its grounds should be acquired for the public, and appointing a committee to make arrangements for an appeal for funds from the Mansion House and to consider the most practical scheme for the future management and control of the Palace. He said it would be a species of high treason for the British nation to allow a great memorial to the beneficent philanthropic genius of the Prince Consort to be destroyed in the first years of the reign of his Royal grandson. They had already received promises of sums amounting to £7,000. Before the Lord Mayor could make a public appeal for funds he must be assured that the deposit had been forthcoming, and it was hoped to bring that £7,000 up to £20,000, which would be a suitable deposit. They would then be in a position to appeal to the various authorities represented at that meeting on the terms that they had already acquired the Palace for a definite sum of money, the sum of money involved being, say, £300,000, and those authorities would be urged to contribute so much towards that definite sum. Lord Plymouth seconded the resolution. Lord Tenterden, on behalf of the council of the King Edward National Memorial, said they were prepared to join forces with the Mansion House Fund and to contribute £5,000 towards the deposit. The resolution was carried unanimously.

Plant Mites.—An interesting paper on plant-inhabiting mites of a useful nature has, we learn from "Nature," been published by Prof. G. F. Scott-Elliot. The red spider and other inimical mites are well known, but the beneficial mites, although exceedingly common, have received less attention. Their homes, in the shape of small hollows behind hairs on the undersides of leaves on trees, are termed acarodomatia; they are not confined to dicotyledonous trees and shrubs, as was supposed, but are common on tall herbaceous plants, and the author has found them on the leaves of Solomon's Seal. With respect to their sphere of usefulness, it is asserted that they feed on scale insects, fungus spores, and other pests. The author suggests that with bacteria they help to prepare organic dust particles for the benefit of plants.

Royal International Horticultural Exhibition 1912.—Among the most recent donors of special prizes are Messrs. Clay and Son, who are offering for competition in the rose class a silver-gilt bowl, valued at eighty guineas. Horticultural sundries will, we are informed, exhibit a completeness that has not been previously seen in this country.

The Narcissus Fly.—It has for a long time been assumed that the Narcissus Fly (Merodon equestris) confines its attacks to narcissi, but, according to the contributions from the Wisley laboratory to the current issue of the Royal Horticultural Society's "Journal," the fly lays its eggs on other bulbous plants and the larvæ go through their various stages within their bulbs. Mr. F. J. Chittenden writes, with reference to this matter: "In November, 1910, a bulb of Habranthus pratensis, which had lain some time unplanted, was sent to us. The bulb had been imported from Holland. On examination it was found to be almost entirely eaten away inside, and had the usual tunnel opening below, while it contained a grub which we believed to be that of Merodon equestris almost full grown. The next post brought from another source a bulb of Vallota purpurea containing two precisely similar grubs. The latter was one of a number of vallota and eucharis bulbs which had been sent in May, 1909, from Sierra Leone. Most of them when potted up grew well, but some failed to develop but weakly. Examination showed the presence of one or more grubs in each, and the characteristic hollowing out of the bulb by the grub. The bulbs were potted up into separate pots, covered with muslin to prevent the escape of the fly when it should hatch, and kept in a greenhouse during the winter. The habranthus bulb was completely destroyed by the grub which pupated in the soil. At the end of March the fly hatched out, and examination showed it to be the narcissus fly, Merodon equestris, as had been suspected from an examination of the grub. The fly was sent to the British Museum (where it has been deposited), and Mr. E. E. Austen, who kindly examined it, confirmed the identification." The grubs with which the vallota bulb was infected became pupæ, but the flies did not develop properly. There is, however, according to Mr. Chittenden, no doubt as to the insect being Merodon equestris. It is further stated that it does not seem necessary to suppose that the vallota bulbs were infected when they were imported, for they were received in England and potted up at the time the fly would be on the wing in this country.

GARDEN RECONSTRUCTION.

The beautiful can always be made more beautiful in the case of a flower garden, so that the owner of a garden who is perfectly satisfied with his pleasure grounds as they are must obviously be in error. The more the gardener loves his craft the larger are the opportunities that he sees, and the greater his desire to make use of them.

Small alterations are sometimes not sufficient to meet the wants of the garden; if it has been laid out upon faulty lines nothing but entire reconstruction will be successful. This is not as difficult a business as may be feared, though undoubtedly a long one. Some gardeners always prefer to lift the plants in beds or borders before thoroughly forking and manuring the soil in autumn or early winter, and, though this practice is generally condemned by scientists, the fact remains that shrubs and perennials can quite safely be stored away ten days to a fortnight with their roots in moist compost in boxes kept in airy sheds.

A wrong design in a garden is a fault be it remembered that no merits of the flowers can hide. If the ground is crossed by awkward, ungainly paths, too narrow, set so as to leave large formal plots for beds, and the straightest of monotonous borders, then it should be replanned. Much of the gravel can be left untouched; new turns in walks, encroachments of border edges so as to form waves here and there, with corresponding semicircular additions to the paths, will soon take off the stiff ugliness. The allotment-like plots can be irregularly cut through by winding walks, or rockery banks thrown up in them here and there will provide hills and valleys, sunshine and shade alternately. A glade of hollyhocks or mulleins, delphiniums, or pillar roses, made through the centre of a plot becomes a lovely floral nook, and if the inner portion is turfed over, or sown with grass seed, the result will be yet more pleasing.

Alterations in the shape of lawns is best done in autumn, for if turves are laid down and well beaten frequently during winter there will be no unsightly patches to vex the eye the next spring.

Simply by adding a large semicircle of turf to the beginning or end of an oblong lawn the garden can be given those rounded outlines that are infinitely more pleasing than angular ones. To adorn the edge of the new portion small round beds can be cut out, a pillar rose and clematis planted in each alternately, on a carpet of pinks and violas. If height is not desired then a novel and charming effect results from cutting a twelve-inch border a foot from the edge of the turf and repeating its curve. This should be filled with hyacinths and crocuses, then with begonias and miniature sweet alyssum each year.

Setting a rustic summer-house on the end of a lawn, rather to one side of it, cutting out a meandering gravel path to it from the nearest existing walk, then making a clump of flowering evergreen shrubs on the other side, alters a too straightly-planned garden satisfactorily.

Excavations are not sufficiently popular. By digging out a semicircle in a plain plot of level ground to a depth of six feet, throwing the removed soil up to form a bank on one side of the hollow, placing rocks to hold up the sides of the small dell, and conducting a winding grass or gravel walk with a few stone or wood steps down to it, an interesting spot is quickly created. By the time Wichuraiana roses trail down the bank, with White Broom, a Philadelphus Lemoinei, two or three weigelas and cotoneasters, in association with them, and when the sunk-rockery blushes pink with monthly roses which will scarcely ever be flowerless in that shelter, or is blue with violas, snow-white with pinks, or orange, copper, and crimson with dwarf chrysanthemums, the value of the improvement will be keenly appreciated.

M. H.

DESSERT PLUM COE'S VIOLET.

A.M., R.H.S., October 24, Mr. J. Vert, Audley End.

NEW PLANTS, ETC.

CHRYSANTHEMUMS.

Mrs. W. Garner.—A beautiful large-flowering single variety that has sported from Bronze Pagram. It has bright bronze colouring, the petals tipped with gold, and their golden bases forming a zone round the disk. F.C.C., N.C.S., October 23. Messrs. Cragg, Harrison and Cragg, Heston, Hounslow.

Wonder.—A refined and graceful Japanese variety, with narrow florets, that twist prettily at the apex. The ground colour is rich old rose, but all the central florets have a rich terra-cotta shading. F.C.C., N.C.S., October 23. Mr. Martin Silsbury, Shanklin, Isle of Wight.

Gertrude Pears.—A bright and attractive Japanese variety with fairly broad reflexing florets of a rich and beautiful shade of ruby-crimson; a fine addition. F.C.C., N.C.S., October 23. Messrs. W. Wells and Co., Merstham.

Mrs. W. Hookey. — A very big Japanese variety with long, broad, drooping florets of a clear straw yellow all over the centre, but with rosy shading towards the tips of the lower florets. Commendation, N.C.S., October 23. Messrs. W. Wells and Co., Merstham.

Miss Venetian Hartman.—A very deep Japanese bloom, but not a very broad one. The narrow florets droop and curl prettily, and are a charming shade of lemon-yellow. Commendation, N.C.S., October 23. Mr. Walter Jinks, Newlands, Thames Ditton.

Surprise.—A showy and very free flowering border single variety; the blooms are a couple of inches across and the colour is bright terra-cotta. Commendation, N.C.S., October 23. Mr. H. J. Jones, Lewisham.

Yvetta Richardson.—A useful single border variety of good form, and very free flowering. The colour is an attractive shade of reddish rose—almost crushed strawberry. F.C.C., N.C.S., October 23. Mr. H. J. Jones, Lewisham.

Thorpe's Terra Cotta.—A large reflexed variety making up rounded solid flowers, borne on long stiff stems; the colour is rich bright bronze. Commendation, N.C.S., October 23. Mr. H. Thorpe, Worthing.

Madame Auguste Nonin.—An old market decorative variety that was sent under the name of Mrs. George Perry. The colour is a lovely shade of silvery-pink. Commendation, N.C.S., October 23. Mr. G. Perry, Hayes.

E. Cox.—A useful market variety. An incurved sport from the well-known Moneymaker, with solid creamy blooms, carried on long stems. Commendation, N.C.S., October 23. Messrs. Cragg, Harrison, and Cragg, Hounslow.

Walter Parsons.—A handsome and refined Japanese variety with reflexing and slightly twisting petals; the colour is rich chestnut, suffused with gold. F.C.C., N.C.S., October 23. Mr. H. W. Thorpe, Worthing.

Coronation.—A graceful Japanese variety with fairly broad drooping petals that twist a little at the ends. The colour is rich deep rose, with silvery reverse. F.C.C., N.C.S., October 23. Messrs. J. Stredwick and Son, St. Leonards.

SENECIO SAXIFRAGOIDES.

An evergreen perennial that it is hoped may prove hardy in this country. The foot-high hairy scapes are branched, and carry a number of bright yellow flower heads that are each about 1½in. across, and composed of from twenty to thirty ray florets around an orange-yellow disk. As a rock garden plant this would be a success if sufficiently hardy; it comes from New Zealand. Bot. Mag., t. 8,394.

Ampelopsis Lowi.—This pretty ampelopsis, with small, deeply-cut leaves, colours as freely in the autumn as the best forms of Ampelopsis Veitchi. It was distributed a couple of years ago, and I am surprised that we do not see it oftener, as it is of neat growth, and the laciniated foliage renders it very distinct.—W. T.

NEW BOOKS.

MANURES FOR FARM AND GARDEN CROPS.

By W. Dyke. (W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London, E.C.). Price 1s. paper boards, 1s. 6d. cloth; postage in each case 2d. additional.

A full recognition of the importance of deep digging and trenching, and a thorough breaking up of the soil in the process is a great aid to successful cultivation, whether it be of useful crops or ornamental plants; but it should not, as is frequently the case, be regarded as all-sufficient. It is certainly not less important to the cultivator that he should possess a knowledge of the chief constituents of the various classes of soil under cultivation, and an acquaintance with the different fertilisers in general use, so that he may be in a position to provide the plants with food that is exactly adapted to their requirements. It is essential to the full development of the plant, to whatever class it may belong, that the soil be so prepared as to enable the roots to extend freely on all sides, and to a depth sufficient to prevent any check to growth during short periods of drought. But it should not be forgotten that the roots not only require a soil so well broken up as to allow them to extend freely, but must have liberal supplies of plant food within their reach so that they can absorb not only water, but nutrient matter that can be readily assimilated and utilised in the building-up of the tissues of the plant, and perfecting the part or parts for which it is specially grown. It is possible for those whose knowledge is of merely an empirical character to provide most plants with a sufficiency of food, but there is the risk when the practice is in accordance with rule of thumb of applying some constituents in excess of requirements, and if this does not bring about a result different to that desired, it involves more or less waste.

With a full appreciation of the value of scientific manuring in garden practice, we turned to Mr. Dyke's book with considerable interest, because we have long known him as a successful cultivator, and have been acquainted with the attention he has devoted to the study of fertilisers in connection with various crops grown for market and home use. We not only opened the book with interest, but, knowing the author and his work, we indulged in the anticipation that it would contain exactly the information required by the general body of practical cultivators. Our anticipations have been fully realised, and we should fail in our duty to our readers were we not to advise all who are desirous of improving their knowledge of fertilisers to give instant attention to the large amount of information relating to them which the author has placed at their disposal.

The book is divided into three parts, and the chapters included in the first part contain a full and clear statement of the science and practice of manuring. The second part is devoted to classes of manures, and in the several chapters general, nitrogenous, phosphatic, and potassic fertilisers are described, and directions given for their use. In the third part formulæ are given for the different crops and plants that come under the gardener's care, and as these are accompanied by full information as to the means by which the best results can be obtained in their application, the value of the section is great.

APPLES AND PEARS.

By George Bunyard, V.M.H. (T. C. and E. C. Jack, 16, Henrietta Street, London, W.C.) Price 1s. net.

There is no dearth of books in which the selection and cultivation of apples and pears are dealt with, but there is not one, so far as we are aware, exactly like this, and we are not acquainted with any work that is obtainable at about the same price that can compare with it in the assistance that it is able to render the inexperienced cultivator in carrying out the various details that are essential to success. It would be superfluous to state that the author is a past master in all that relates to fruit cultivation, because this has been amply exemplified by the collections of fruit that have over a long series of years been presented by his firm to public notice. But it should be said that he possesses in a marked degree the ability to convey his wide knowledge to others in such manner as to enable them to readily understand it. We have had evidence of this faculty on many occasions, but at no time or place have we been more impressed by it than in the perusal of this the most recent of Mr. Bunyard's works on fruit culture.

The first chapter is devoted to historical notes, and the references to the works of Tusser, Leonard Marshall, Gerarde, Markham, William Lawson, Ralph Austen, John Lawrence, Switzer, and others of the old writers form very interesting reading. Following the introductory chapter are chapters on such subjects as the purchase of trees and choice of positions, varieties for different aspects, preparation of soil, and planting, pruning of branches, root-pruning, pot culture, shelter, insect pests, and a monthly calendar, and these while not lengthy contain ample information on the respective details.

The book is illustrated with eight coloured plates of apples and pears.

HOW TO COOK VEGETABLES.

By C. Herman Senn. (The Food and Cookery Publishing Agency, Westminster, S.W.) Price 2s.

It is not less important to the community that vegetables should be cooked properly than that they should be grown to a high degree of perfection, and therefore any aid that can be obtained in bringing about an improvement in the preparation of vegetables for the table should receive a warm welcome. The book before us should prove of much value as a work of reference on the cooking and serving of the various vegetables that find favour in this country, and also for the information it contains on the cooking of kinds that are as yet unknown in the majority of households. It has been written by an author who is fully conversant with his subject, and has therefore been in a position to wholly rely upon his own experience in his description of the five hundred different ways in which vegetables can be prepared for table.

Lilium tigrinum Fortunei.—Imported bulbs of this lily have, as usual, flowered finely with me this year, but instead of tall shafts 6 to 7ft. in height, as I have had in other years, they are little more than a yard in stature. This is, I take it, owing to the heat and drought, as they came away in the spring as vigorous as ever. —W. T.

Rose Cuttings.—To obtain a stock of home-grown roses on their own roots, cuttings should be put in now. Suitable material for propagating purposes will usually be found in this season's secondary growths, which break away from the first growth below the flowering point. It is important that the wood should be in a fairly firm condition, for, if soft or tender, it will rot. The growth selected for the making of the cutting must be removed from the older portion with a heel attached, that is the slightly swollen part, caused by the bud before it commenced to break. This can be accomplished with a sharp knife, cutting in an upward direction. The length of a strong cutting should be about nine inches, but some of the weaker ones must be shorter. If only a few are to be propagated, they should be inserted in pots filled with sandy soil, made very firm, and placed under a handlight. When a large number are required cold frames may be brought into use on a cool, shady border, and the cuttings planted in the soil, which must be quite firm.—E. C. Pooley

THE MERRYWEATHER DAMSON.

Not a few efforts have been made during late years to improve the common damson by mating it with some of the latest plums, but Nature seems to have taken the work into her own hands, and the result is the Merryweather damson. This fine addition to our hardy fruits is a chance seedling, with the habit of growth of a Victoria plum, fruits of plum size, and the flavour of a damson. It is introduced by Messrs. H. Merryweather and Sons, Lim., of Southwell, Notts, who have had the original tree under observation for a long while, and are thoroughly convinced that the variety has a great future before it. The young trees come into bearing at two or three years of age, and they continue to fruit regularly and freely. The flavour is excellent, and the fruits are good eating, as well as of great use for culinary purposes. Our illustration is from fruits brought up to the recent great fruit show at Westminster by Mr. Merryweather, jun.

Aubrietia Purple Robe.—There are now many very fine varieties of aubrietias, some of them so good that only new ones of exceptional merit will be given a place in spring-bedding arrangements. The variety named above is one of great value. When plants become established on a rockery, for instance, the flowers show up to great advantage. The shoots made are rather long, and depend gracefully from the edges of stones, and, being covered with the deep purple flowers, they look very charming. Large tufts of it also look well growing on flat shelves on the rockery. Aubrietias are equally suitable for edgings to spring flower beds.—G. B.

SCILLAS.

Scillas form a group of exceedingly beautiful hardy bulbous plants to which our gardens owe much of their beauty in spring and summer. With rare exception the genus is one that admits of freest representation in garden, orchard or woodland, and where the latter condition prevails the possibilities of pictorial gardening with bulbous plants like scillas, has scarcely any limit. It is under such conditions that Scilla nutans, the "English Blue-Bell," attains its maximum development and appeals to every taste, and is typical of what is best in English woodland scenery.

Scilla nutans is one of the easiest species to establish; it prefers a fairly deep soil, and where such obtains, it should be planted out at a depth of six inches from the surface. It may, however, be grown in most woods, including those of pure beech, where the surface soil is closely packed with roots; even there it is able to maintain a hold, although never attaining to that perfection seen under more favourable conditions. The type produces blue flowers on graceful arching spikes, while there are also white, flesh-pink and deep rose forms; the latter, as garden plants, become of great value when planted in quantity in shady borders or semi-wild spots, grouping them with native ferns or plants like Solomon's Seal.

Scilla hispanica (campanulata) may be used in common with our native species for beautifying less formal parts of the garden. It, also, is robust in growth, with erect spikes from 15 to 24 inches high, and open campanulate flowers; the colours embrace, blue in various shades, white, pink, and rose.

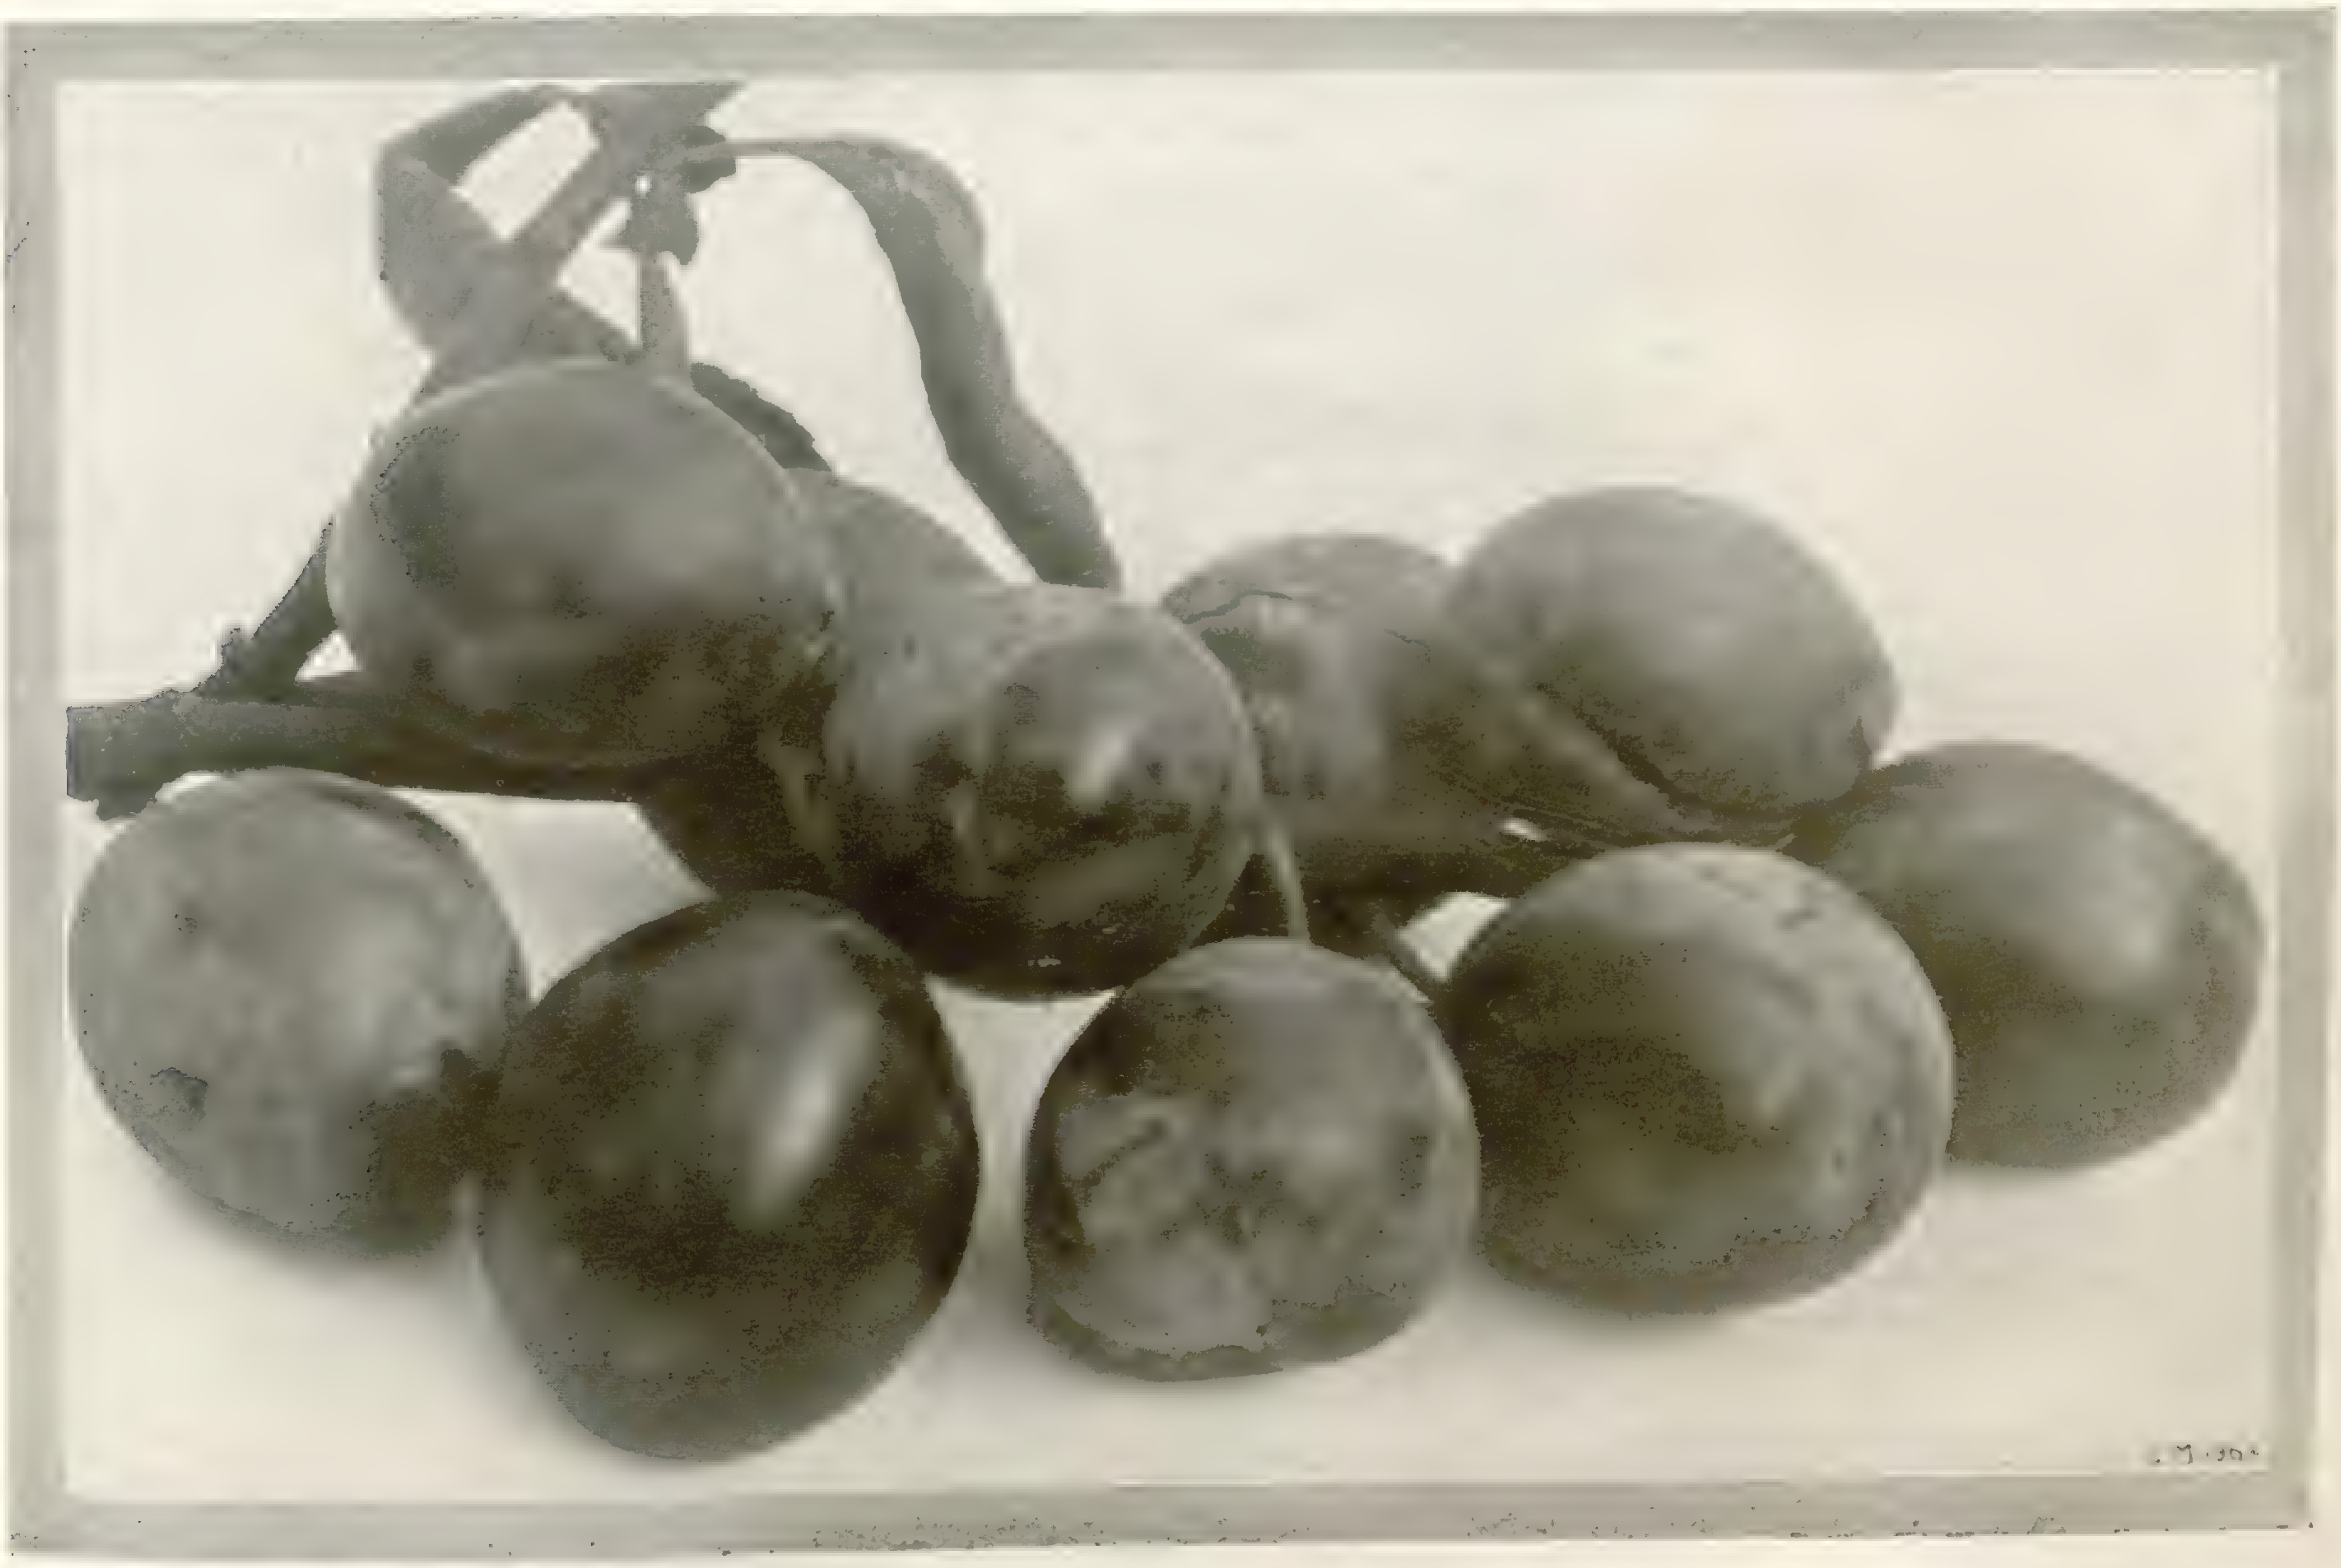
Scilla patula is the most robust and tall of the wood hyacinths, the variety Excelsior, with lavender-blue flowers, and Major, with flowers of lilac-blue are the two best.

One of the most charming members of the genus is Scilla bifolia, a dwarf species that flowers along with snowdrops in spring; the flowers are a bright blue, and are charming in contrast with the chaste purity of the snowdrop. Of this species there is a white and pale rose coloured form. Scilla siberica is another dwarf species, having very deep blue flowers that attain a height of four to six inches, the type flowers much later than S. bifolia, and is also a fortnight later than the variety S. taurica, which has flowers of a lighter blue; there is a white form of S. siberica that is excellent in combination when sparingly planted with the type. Scilla italica is a pretty dwarf subject with lavender-coloured flowers that open in May.

Scilla autumnalis grows to a height of six to nine inches, and produces purple-blue flowers in autumn. The variety japonica has rose-coloured flowers, while there is also a white form.

Scilla peruviana, also known as the Cuba Lily, produces huge corymbs of flowers of a rich blue shade, early in summer. It is not quite hardy, and must be planted in light, well-drained soil, in a sheltered spot with some protection to the plants in winter. Scillas succeed readily in any good soil of fair depth, their greatest beauty is displayed then in quantity, so that in planting with a view to natural effect, a few well-chosen varieties will most generally give the best results, being more effective than an exhaustive collection. Scarce or rare varieties are best accommodated in borders devoted to choice subjects, or planted on the rock garden, where their beauty is fully disclosed amidst appropriate surroundings.

Thomas Smith.



THE MERRYWEATHER DAMSON.

A valuable damson, remarkable for its productiveness and the large size and high quality of its fruits.

CULINARY PEAS IN 1911.

The summer of 1911 will long be remembered by gardeners as one of the most trying on record, especially for keeping up a supply of culinary peas or other choice vegetables. No sooner did peas come into bearing than they were quickly over, and one can sympathise with those who, under such trying conditions, were expected to keep up an almost daily supply of tender peas.

Most gardeners have their pet varieties of peas for the main crops, and this is partly due to these being most suitable for their particular soil—an excellent reason why they should grow such kinds in preference to others. But sometimes there is a strong conservatism abroad, and no desire to make changes; this is not such a good reason, because it is always wise to try some other varieties to see if the old kinds are being improved upon.

It is a well-known fact among experienced gardeners that several varieties of garden peas are quite first rate in some soils, while in others they are almost useless; it is therefore a matter of importance that there are many varieties to select from to meet the requirements of everyone. The past season has demonstrated very clearly the merits of some varieties.

In noting these one may include some of the earlier varieties as well as later ones, and one of the best, if not the best, for early crops, is Eight-weeks, sent out by the Holborn firm; those who have grown it speak very highly of it. A pea suitable to follow this is Little Marvel, a wrinkled marrow, 18 inches in height; this is so highly esteemed by gardeners that they grow successional crops through the season. The Pilot is another pea about 3ft. high that is excellent in every way as an early variety, especially if a re-selected stock is grown. Early Morn, although not of recent introduction, is one of the best 3ft. early marrow peas. It quickly develops, and should not be sown too early on heavy land. The variety Thomas Laxton was a good early variety of its time, but is now displaced by Edward VII., a variety which has gained an Award of Merit as an early marrow pea. A good description for Snowdrop is an early Ne Plus Ultra, which should be sufficient recommendation to growers who have not yet tried this pea. Laxtonian, which I grew when it was first sent out, is so altered and improved by re-selection that it is now scarcely recognisable. Duke of Albany and Alderman, if re-selected stocks are obtained, fully maintain their position as two of the most reliable peas which can be grown. A pea which has Duke of Albany for one parent is Carter's Harvestman. This variety has good cropping qualities, grows about 5ft. high, and promises well.

Among dwarf peas Commonwealth has been very satisfactory this season; it is about 2ft. in height, is a wonderful cropper, and has peas of a deep green colour. Autocrat, as usual, has been very satisfactory, and in those districts which were favoured with a few showers late sowings have proved very useful. Two varieties of late peas which have withstood the very trying conditions of the past summer are Dreadnought and Michaelmas; the last-named is fairly well known as a reliable kind for late cropping, while Dreadnought is very appropriately named, for a pea which withstands the drought of 1911, north and south, is one that may well fear nought, even in exceptional seasons. It appears to be equally at home on heavy and light soil, and good in every respect. Latest Giant is a marrowfat pea of robust habit, and, as the name suggests, is a late variety; it crops well, the pods are well filled, and Gladstone being one of its parents, it should commend itself favourably to all.

The past summer has demonstrated the beneficial effects of deep cultivation, and of maintaining a fine surface tilth; occasional thorough waterings, not sprinklings, and heavy mulchings, have repaid the extra labour entailed. The advocates of "dry farming" should be satisfied, for the summer of 1911 has shown how great is the value of the system. Paul T. More.

WHO SHALL RULE?

The question has been recently mooted as to whether the architect or the gardener shall be responsible for the planning of the gardens which must necessarily encompass any new or remodelled residence. The point of view is that the architect desires that the garden shall be dominated by and subsidiary to the residence, with its formality repeated in a like degree. On the other hand, the gardener is represented as making the garden a nursery of flowers, and that blossoms necessarily come before design in his thoughts and arrangements.

The making of a garden which shall not violently oppose the outline of the house, and which shall also be artistic and replete with beauty, is a very important undertaking. Differing styles of architecture will certainly require differing treatment, and the fullest attention must be paid to the conformation of the building, and to allow the garden to frame and soften this conformation in the best possible manner.

Now, to come rapidly to the crux of the matter, it may be asked, "whether the architect or the gardener are the better fitted for the task in hand?" The architect, with his inherent formalism; or the gardener, with his mind centred upon the culture of plants and trees? It must be admitted, with reference to capabilities, that much weakness exists on both sides. I, for one, would strongly combat the intrusion of the architect in what are essentially garden matters, just as strongly as they would refuse to hear the views of a gardener upon structural details. There is no "go-between" in this matter. The two professions have little in common, save that the taste of the gardener must be utilised to improve the surroundings of what the architect has seen fit to create. This, then, is my contention—the architect to his building, and the gardener to his garden.

To make a garden requires good taste, a knowledge of plants and shrubs, and a thorough love of the work in hand. The gardener, if he is worthy of the name, can see just the subjects necessary for the embellishment of a certain place as well as if they were already growing there. His natural love and knowledge of flowers enables him to decide the best positions, both for beauty and effectiveness, of any particular section of plants or trees.

He can assign a position for the rose garden, or a rock garden, or an ornate series of flower-beds, by his knowledge of the requirements of the plants desired, and their effect when in growth and blossom. The successful culture of plants depends largely upon the position being right, and the gardener must remember that not only must the position be right, but that the garden must be properly balanced, both with respect to its parts, and in its relationship to the residence it surrounds.

On the other hand, there are gardeners who have never really considered the question of "landscape" and "decorative" gardening. Their work has probably been confined to the care of existing gardens, and consequently they have not really felt the need of obtaining a knowledge of garden making, I would quietly urge upon my readers the thought that garden art must rank equally as important as good culture does to most growers. We must not be content to grow good plants, but we must place them in suitable positions. To gain telling effects; to secure harmony and due proportion; to interest and charm the mind and eyes of all; to avoid cut-and-dried formalities. These must form notable points in the gardener's working creed. He must remember (and it is not always easy) to let the artist which is in him have full play. Art and good culture, hand in hand, will suffice for any garden.

Therefore push forward your studies in this direction. Let it be possible for a good knowledge of designing to be acquired by every true gardener. I do not wish to make every gardener a draughtsman, but rather that he should come to realise the full values of plants, to know at a glance the type of subject or the most fitting design for each particular aspect.

It must ever be borne in mind that the architect is usually a poor gardener. He does not value plants or shrubs for their beauty, or for natural effects which they may create, but simply considers their usefulness in making a line here, a break there, or to darken or contrast with the outlines of his buildings. This, then, is sufficient warrant for the gardener to fill the gap between the two professions. Let him make it his own province to know the value of all that links the garden to the house. The formal path, the terraced walls, the steps from one altitude to another, the placing and design of pergolas and garden screens, and the many other incidentals, will afford him a good field for study, especially as it is so very necessary in these days.

In conclusion, may I say that garden-making has not yet reached its greatest heights. We travel from improvement to improvement feeling that the ideal which is set before us is not yet reached, though possibly it may be that we shall never attain to the perfect garden, for the more progress we make the higher we unconsciously raise our ideals.

P. S. Hayward.

CALLICARPA PURPUREA.

It is usual to associate this plant with the indoor garden rather than with the shrubbery, for all who have had to keep a conservatory gay have been pleased to use it for the sake of its showy purplish berries, which appear in clusters from the leaf axils. Nevertheless, it may be grown out of doors, and, except in very severe winters, it escapes serious injury to the branches. Unfortunately it blooms too late in the year for its fruits to set, consequently we are unable to include it amongst the showy fruiting shrubs of our outdoor borders. At the present time, mid-October, plants are bearing a profusion of small purple blossoms, which are sufficiently showy to command attention from passers by.

The species is found in both China and Japan, and as it covers a wide area of country, it is possible that some forms are hardier than others; and were an effort made to introduce specimens from the more northerly districts in which it grows, plants capable of producing outdoor fruit might be obtained. As it is, one can hardly say that it is a suitable subject for general cultivation, although the late date at which the flowers appear might be counted as a point in its favour. For the small garden, however, there are many other shrubs which would more worthily occupy the ground.

Kelway's Delphiniums

The
Bold Delphinium

BOLDNESS is the outstanding characteristic of the beautiful KELWAY DELPHINIUMS, which grow to a height of from four to eight or more feet and bear masses of fine shapely blooms in all shades of blues and purples. They thrive with a minimum of attention in almost any soil and situation. They show to the utmost advantage either massed or as a part of the celebrated Kelway Colour Border (Regd.).

Choice named collections of Kelway Delphiniums
24/- 34/- 56/- a dozen.
Kelway Colour Borders, 15/- to 25/- for 10 sq. yards.

The Kelway Booklet, "Gardens of Delight" (6d. post free), gives full details.

SPRING BEDDING SUGGESTIONS.

The London parks and gardens serve as a very fine object-lesson in the matter of artistic floral decoration, and, happily, the "powers that be" afford every encouragement for a lavish display that is worthy of a great capital. Beautiful indeed is the display of spring-flowering bulbs and plants, and I propose to offer a few remarks as to effective combinations noted last spring.

A very large bed filled with Hyacinth King of the Blues, Narcissus Horsfieldi, and Tulip Ophir d'Or, with a dense mass of Aubrietia Leichtlini, acting as a carpet, was fine indeed, as was also an oblong bed containing about a thousand Proserpine and Snowball tulips arranged in alternate fashion, a wide belt of Myosotis Royal Blue doing much to enhance the beauty of the whole. A huge triangular bed held tulips in variety, mounds, irregular both in size and outline, being planted with Keiser's Kroon, Proserpine, Thomas Moore, Joost Van Vondel, Bacchus, Rembrandt, and Ophir d'Or, while between the mounds, and as a framework, White Joost Van Vondel figured.

Two feet high plants of Cerasus chinensis roseus fl. pl., literally smothered with blossoms, were associated with a glorious mass of polyanthuses, and presented a charming picture, and the same remark applies to dwarf plants of lemon-coloured cytisus, around which nestled fine masses of alpine auriculas. A great mass of Hyacinths Leonidas and La Grandesse, arranged in indiscriminate fashion, was very pleasing, and the single-flowered arabis supplied a first-rate carpet. A wide stretch of bronzy-golden wallflowers, with hyacinths in various shades of blue thinly interspersed among them, struck a rich note, while in another park the extreme brilliance of Tulip Imperator Rubrorum was toned down by rubbing shoulders with the double white arabis.

I was impressed with the effect created by bringing together Hyacinths Gigantea and Leonidas and Narcissus Stella, and yet another fine combination of Tulip Joost Van Vondel, Emperor narcissus, and Hyacinth Van Der Hoop. Mention should be made of a large bed carpeted with the new scarlet daisy of immense proportions, White Swan tulips rearing their heads above it. A splendid mass of Muscari botryoides alba associated with Hyacinth Priestley was fine. It was also a good idea to plant Wouverman and Van Der Neer tulips between golden-yellow wallflowers, and the bringing together of Keiser's Kroon tulips and chalice-cupped narcissus is to be recommended. A large stretch of border was planted with hyacinths, tulips, and narcissus in variety, and it was very clear that the bulbs had been mixed together in careless fashion and planted where they fell, and it may also be recorded that no more delightful or artistic feature could be found in that particular park. Walter H. Aggett.

Myrtle Jeanny Reitchenback.—There are several varieties of myrtle now in cultivation, and much as they are admired at all seasons, they are doubly attractive when in bloom. That named at the head of this note is one of the smallest growers, forming as it does a dense little bush, thickly clothed with its tiny dark green leaves. A notable feature is the great profusion in which the blossoms are borne, for when at their best the upper part of the plant is quite a mass of white, intensified in hue by contrast with the dark green foliage on the lower portion. This variety has been known for many years, but it is certainly not met with to the extent that its merits deserve.—W. T.

LADY HENNIKER AND ENCORE APPLES.

At this time of the year planting is commencing in almost every garden, and it is therefore well to bear in mind some of the newer introductions as well as the best of popular sorts when fruit trees are under consideration. A handsome culinary apple that merits attention is Encore, a fine variety raised by Mr. Charles Ross, who obtained it by crossing Warner's King with Northern Greening. A fairly strong grower, the variety is also free cropping, and its solid fruits are particularly valuable inasmuch as they keep well under good conditions until the following June. The large apples are of even outline, roundish, greenish-yellow, with a slight red flush on the sunny side. Encore has received an Award of Merit from the Royal Horticultural Society. Messrs. J. Cheal and Sons, Crawley, Sussex, are the distributors of this useful apple, and our illustration represents fruits exhibited by them at the recent great fruit show at Westminster.

APPLE LADY HENNIKER.

A first-rate culinary variety, raised more than sixty years ago. It was finely shown, as above, by Messrs. T. Rivers and Son, at the recent Great Fruit Show at Westminster.

Lady Henniker is a quite old apple, but it is still a first-rate kitchen variety, and by no means bad eating uncooked. It is in season from October to February. The fruits are large, yellow tinged with red and streaked with crimson, and in some seasons they are very handsome. On orchard house trees they are very effective, especially as grown and shown by Messrs. T. Rivers and Son, Sawbridgeworth; the accompanying illustration depicts a dish of fruit of this variety from Sawbridgeworth. Mr. John Perkins, who was gardener to Lord Henniker, at Thornham Hall, Eye, Suffolk, writing of this apple in 1873, states: "Between the years 1840 and 1850, the late Lord Henniker had great quantities of cider made to give away in the summer months. Several bushels of apple pips were sown in beds, from which the most promising seedlings were selected and planted; these were reduced every few years. The last thinning was about seven years ago, when thirty-three trees were cut out. The tree in question was always a favourite, and it has been carefully preserved. It is much used here when large and handsome dishes of mixed fruits are required for the dinner table. Its appearance by lamplight is most telling. The tree is healthy, and a great bearer."

A PLANTING NOTE.

The planting season is again with us, and no time should be lost by those who have to move either ornamental shrubs or fruit trees. All these move well, and readily adapt themselves to new conditions early in the season while the ground is warm. We usually move several thousands of shrubs and trees each autumn, and always begin the work when October comes round. Visitors who have been here this summer will testify that remarkably few plants die or even look sickly, and this speaks more expressively than any word from my pen of the value of early planting.

When renovating shrubberies the ground should be double dug, as this gives the roots a much better chance of permeating the soil, and also prevents damage from drought in hot summers. If a large bed or border has to be treated it had better be done thoroughly, even if this necessitates a little more time, and is therefore a trifle more costly; it is the better plan for both employer and gardener, to say nothing of the plants. Every care should be taken that, as the plants are taken up the roots are covered with litter or fine soil until the sites are ready for them.

Some good decomposed manure, cow manure for preference, as this is the most lasting, should be worked in with the soil, and the latter should be well broken up with a fork as the work proceeds. Many persons do not think of assisting shrubs with manure, but for most of them it is nearly as essential as for onions or cabbages. W. A. Cook.

Leonardslee Gardens.

POTENTILLAS.

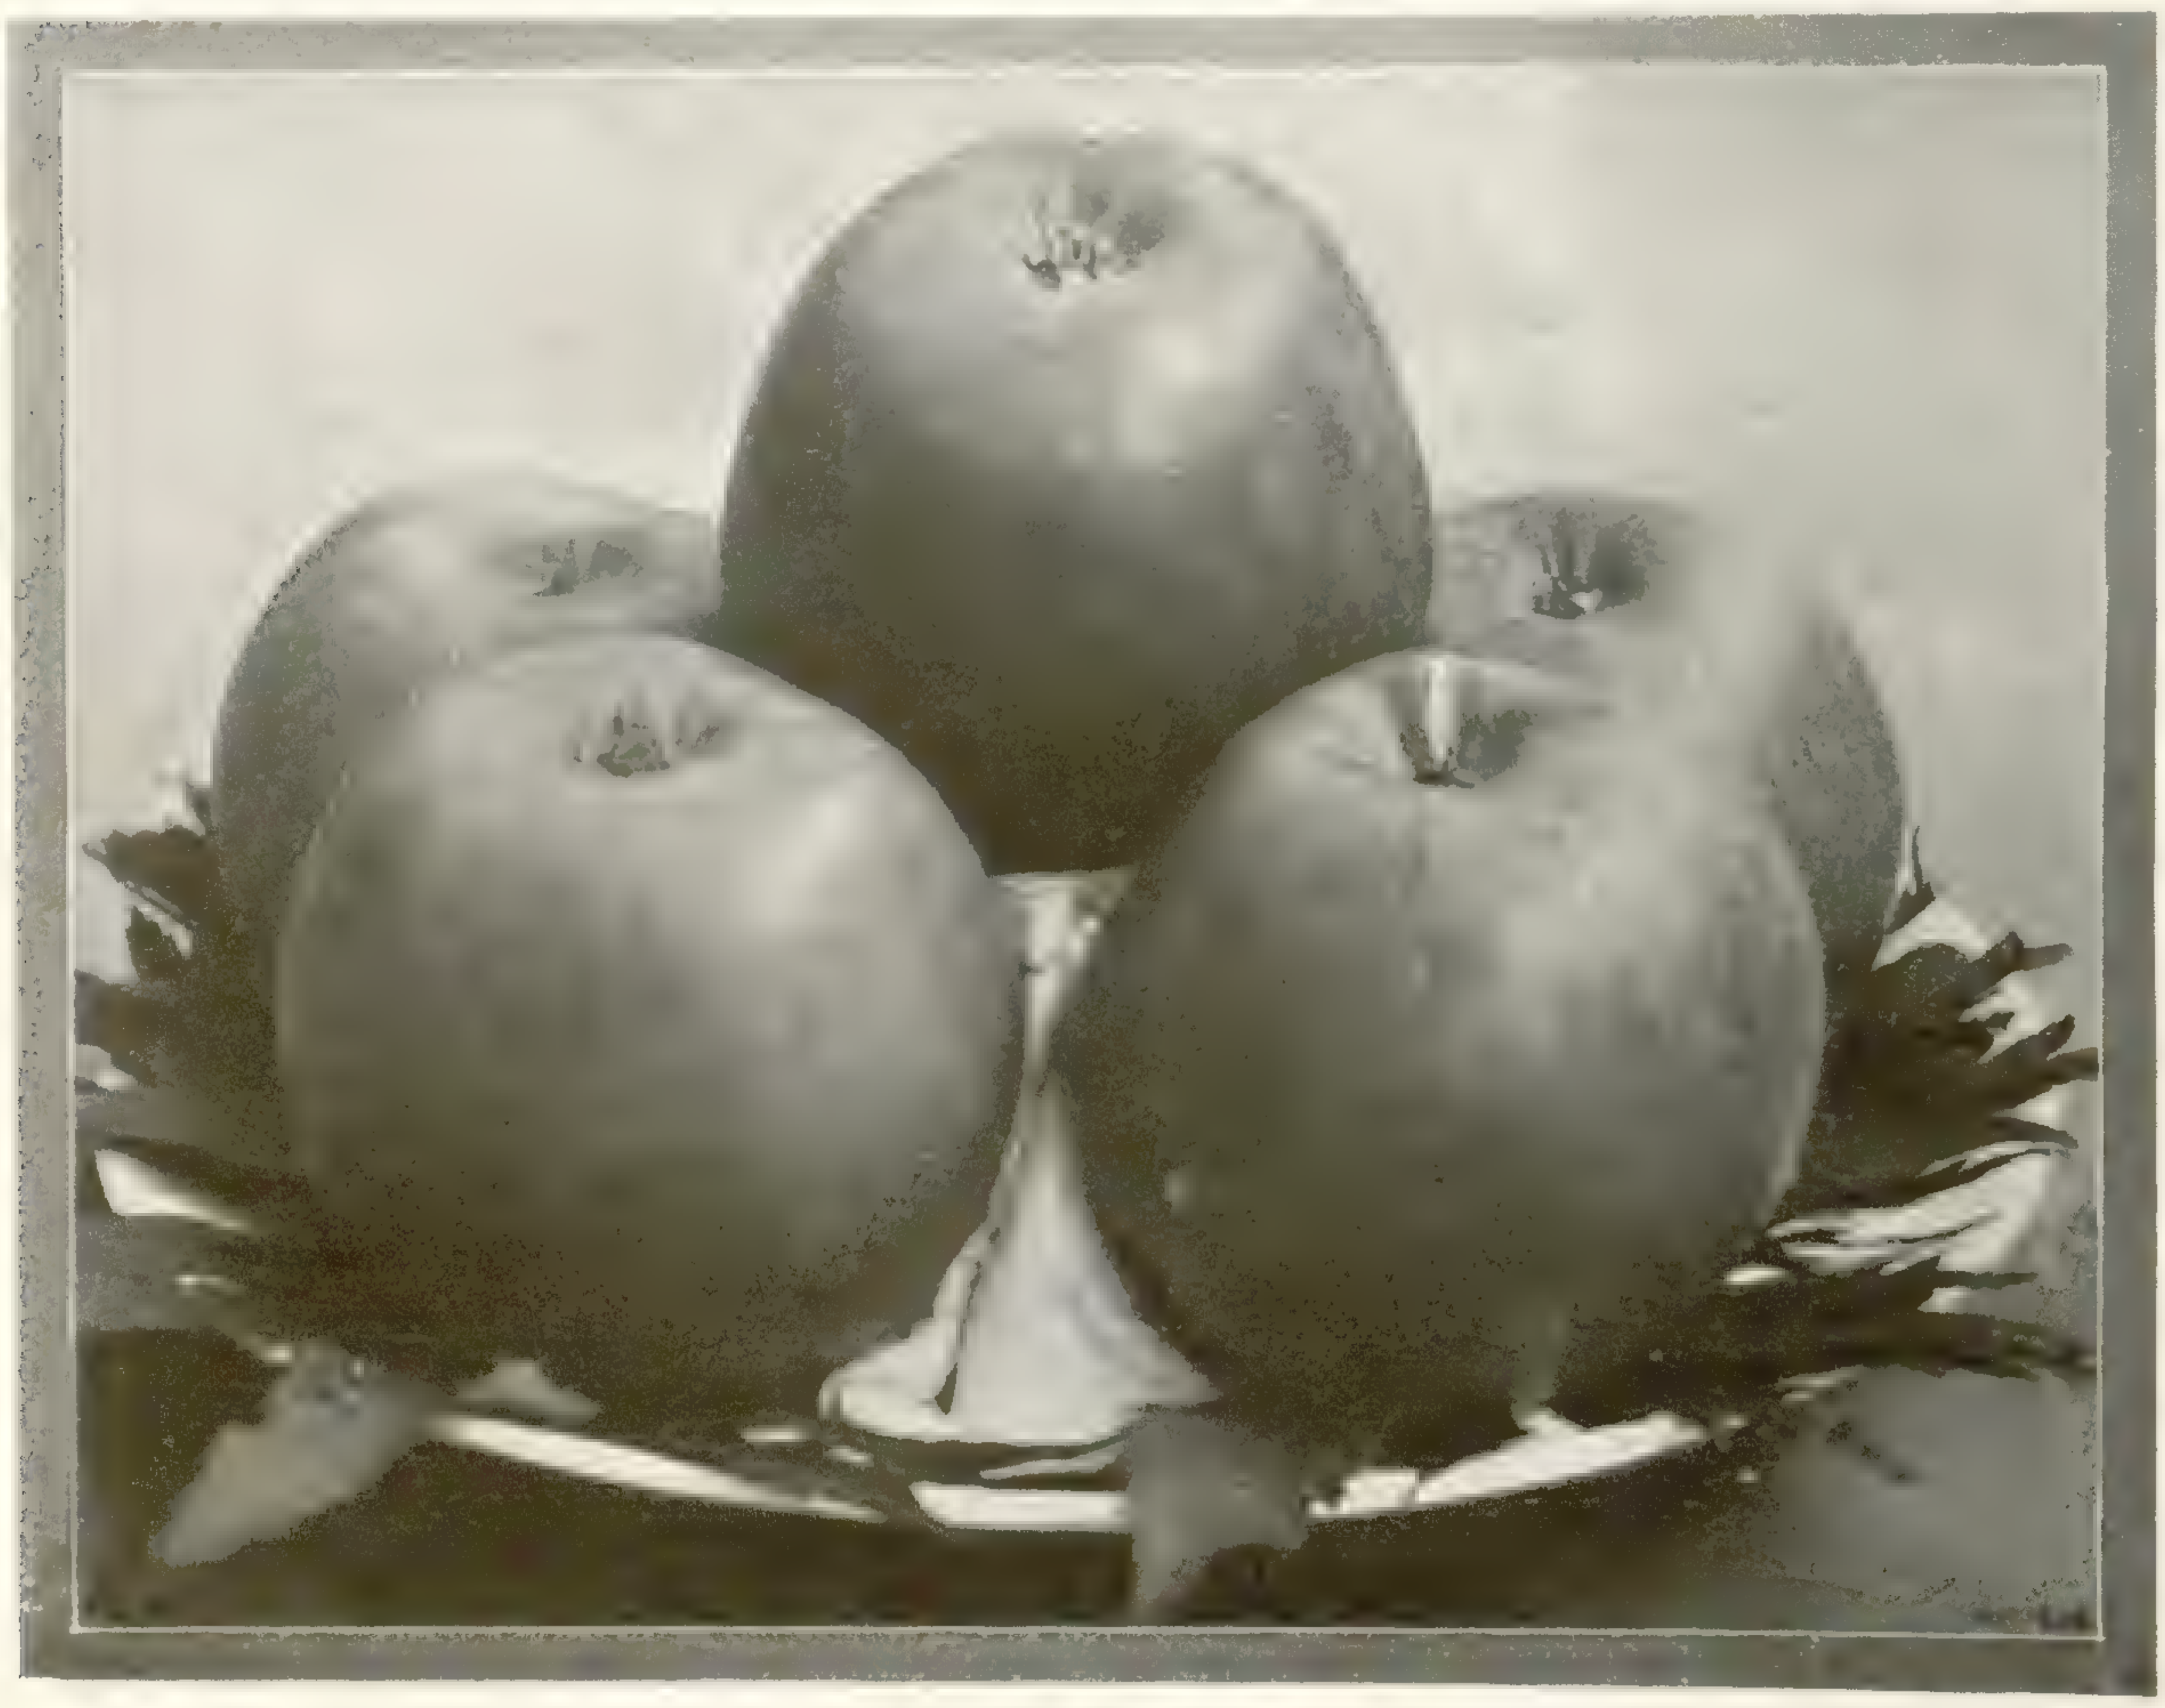
The name potentilla is derived from the Latin word potens, powerful, owing to the potent properties formerly supposed to reside in some of the species. The families to which many of our garden flowers belong are well represented in our British flora, and in this case we have the Silver Weed or Goosegrass (P. anseriva), Creeping Cinquetoil (P. reptans), and the Strawberry-leaved Cinquefoil (P. fragariastrum), which is so often mistaken for the wild strawberry. These are our most common potentillas, or cinquefoils, though we have several others, while botanists describe as many as 150 species the world over. Most of our named garden varieties have been obtained by hybridising two Himalayan species, P. insignis and P. atrosanguinea, neither of them at all unworthy of a place in the garden—the former having yellow flowers an inch in diameter with silver foliage, while those of the latter are deep velvety crimson. The result is seen in the named hybrids, nearly all of which have flowers of one or other of these colours, or, more often, of a combination of the two. The double varieties now almost exclusively mentioned in catalogues are much more showy than the single, and the flowers last longer.

Potentillas are seldom seen except in the gardens of true flower-lovers, which are kept in a state of high cultivation. They will grow in almost any kind of soil, and they like an open position, though they soon pass out of flower if too dry at the roots. For the production of large blooms a deep rich soil is necessary, with just enough shade to give them a respite from the midday heat; but they will grow fairly well on rockeries and sunny banks, and will make a good groundwork between tall herbaceous plants, if not too starved, or even among rose bushes, though rosarians will say this is heresy. It is recommended to water them before the soil becomes very dry, though the amount of drought they will stand is mainly a matter of having the plants deeply rooted, which means deep cultivation. They make very coarse roots which go down very deep, and if the soil conditions are favourable for deep rooting they will stand a good deal of drought. It follows from this that they are not good subjects for moving, and, though they may be increased by division to almost any extent, it is the second summer at least after being planted before they do much good. They increase in size fairly quickly, and if good-sized blossoms are wanted they should be divided and replanted in good rich soil after four or five years. Seed advertised as being saved from the best-named varieties may be obtained, but a good proportion of seedlings usually come single.

There are two different methods of treating the flowering plants. One is the natural or wild garden style, in which they spread over the ground as they will, and this method, or absence of method, is suitable for the rockery, or when they are used as a groundwork. Some recommend pegging them down after the manner of petunias, and a bed of them grown in this way really well, undoubtedly looks very beautiful, especially on a sunny day when the flowers open their widest. On the other hand, with the flowers so close to the ground, a heavy rain completely ruins all the blossoms which may be open at the time.

Many prefer giving them a little support, and this is easily done without unduly marring their natural grace, for, though the flowering stems often begin to fall to the ground before they are a foot high, the stems in themselves are fairly strong, and, if supported for a few inches above the ground, will stand up perfectly well in a way which appears quite natural, though it is not the way the plant grows in a state of nature. Short sticks standing less than a foot out of the ground may be used for the purpose, and three or four flowering stems loosely tied to each one before they begin to fall down, the result being that the growth almost entirely hides the sticks, while the stems grow in an upright position and branch out to some extent, thus producing the effect of a naturally grown plant, which is very handsome when the flowers are fully out in the sun, a large clump spreading out some two feet in diameter. For the production of fine specimen plants of this sort a mulch of manure as soon as the ground becomes dry in May is very helpful. For a bed, a more rough-and-ready way of affording support is to put short, twiggy sticks among the plants, which grow up and hide them while deriving some amount of support from them. The plants usually begin to flower before the middle of June, and last in perfection throughout July and sometimes more or less into August.

For cutting it must be admitted that potentillas are not always satisfactory, sometimes drooping unaccountably the first day. When they do stand, however, very beautiful arrangements may be made with them, using whole sprays, buds and all, as indeed, they can scarcely be cut otherwise. Alger Petts.



APPLE ENCORE.

A new culinary apple raised by Mr. Charles Ross from Warner's King and Northern Greening; exhibited and distributed by Messrs. J. Cheal and Sons, Crawley.

BORDER CARNATIONS NEAR THE SEA.

I was once talking to a nurseryman's traveller about border carnations. My plants rarely lived—if left undisturbed—more than three years in a satisfactory condition, with the exception of the variety Raby Castle; and consequently, I had to layer plants extensively every year. The gentleman in question said: "Border carnations will not do well for more than two or three years in a garden situated as yours is, low-lying and close to the marshy sea-coast, on account of excessive moisture."

For about twelve years previously I had grown carnations in gardens situated within a mile of the sea-coast, both in a northern county and also in a southern one, but the plants did remarkably well for many years undisturbed. These gardens, however, were about one hundred feet, or rather more, above the sea-level, and the foreshore consisted of gravel and sand. When I took charge of the gardens near the marshy ground I was told that my predecessor never relied upon carnation plants after they were two years old. I thought that his system of cultivation was at fault, but after trying my best for ten years, I had to admit that I was beaten. My predecessor had tried for fifteen years. Perhaps some readers of the Gardeners' Magazine have had similar experiences; and, if so, and success has followed any special system of cultivation, no doubt they will tell other readers all about it. G. B.

Clematises for the Greenhouse.—As is usually exemplified at one at least of the autumn meetings of the Royal Horticultural Society, the spring-propagated plants of clematis will flower freely towards the end of the season. At that time they are useful for various decorative purposes, and are at least quite distinct from most subjects commonly used.—W. T.

Cavendishia acuminata.—This is a South American evergreen shrub, which is well suited for clothing the pillars or back wall of the greenhouse. It is of loose free growth, the leaves pointed, oblong in shape, from two to three inches in length, and of a stout leathery texture. The flowers, which are borne in clusters, are tubular, waxlike, and yellowish in colour. They are in the bud state protected by large rose-coloured bracts, which remain for some little time after expansion. In its Andean home these bracts acquire a richness of colouring which we do not see here. Beside this the young leaves are of a pretty reddish hue. In addition to the generic name above mentioned it is also known as Proclesia and Thibaudia, the specific title remaining the same. —W. T.

THE GIANT COLCHICUMS.

Within the memory of most of those whose experience in horticulture extends back over at least a quarter of a century, there was a time when gardens were not beautified in the autumn as well as they are to-day. Ever since the tide turned in favour of hardy plants, and a desire to spend as much time as possible in the garden and the field, the desire to extend the season of floral beauty by the introduction of early spring flowers has steadily grown. A later development has been the extension of the autumn season, and recent years have seen wonderful developments among outdoor chrysanthemums, Michaelmas daisies, solidagos, etc., and there have been numerous introductions of species of flowers, as well as of trees and shrubs remarkable for their autumn glory of fruit or leaf.

The autumn flowering crocuses and colchicums have shared in this development, and both are more popular to-day than they ever were. The colchicums have especially appealed to lovers of hardy plants, and among them none occupy such a high position in popular favour as the giant-flowered Colchicum speciosum and its pure white form C. s. album. C. speciosum, with its cheery bright purple colouring, is a capital autumn bloomer, while the pure whiteness of its albino form makes them very attractive, even at a considerable distance, when a goodly group is cultivated. C. speciosum comes from the Caucasus, and has been with us many years; but the splendid white form has come into prominence within recent years, and no firm has done more to make this beautiful plant widely known than Messrs. James Backhouse and Son, Lim., of York. At a meeting of the Royal Horticultural Society held at Vincent Square on September 26 last, this firm presented a very large and beautiful group of C. speciosum, C. s. album, and other species, composed of many hundreds of fine blooms; the exhibit figured herewith was by far the finest of its kind we have seen. C.

A FINE EXHIBIT OF COLCHICUM SPECIOSUM AND C. S. ALBUM.
Staged at Westminster recently by Messrs. James Backhouse and Son, Lim., York.

POINTS ABOUT STANDARD FRUIT TREES.

In many a private establishment you find on the shelves in the fruit room selected specimens of apples intended for dessert, which are mostly grown, by the way, on dwarf trees in the kitchen garden, but it is as likely as not that somewhere else there is a big heap of apples, not quite as good, perhaps, so regular, or so easily recognised as regards the varieties, but they are invaluable, nevertheless, for the supply of the kitchen from the autumn onwards, and they represent the crop from the orchard, which is outside the precincts of the garden, and is composed of standard trees growing on grass. For the simple reason then that the orchard supplies the bulk of the apples for everyday use in many an establishment it has a value of its own, and even if in some cases it may not receive quite the same attention as the bush, pyramid, and wall trees in the garden, the orchard yields a good interest on the time and money spent on it.

The moment is opportune for discussing the subject because the time is at hand for planting new orchards and filling up others, and in this matter some useful lessons have been taught by the season. One is—plant before Christmas if you can. Why? Because in the first place, the early planter gets the pick of the nurseryman's stock, which is a point worth considering, and he runs less risk of losing his trees if the summer following the planting should happen to be dry. Hundreds of trees that were planted in the spring of this year have gone back, or have only been saved by means of copious waterings and heavy mulchings; whereas specimens planted in the fall of 1910 were settled down in the soil before the spell of drought set in. Get good trees is another golden rule, and by a good tree in the case of a standard I mean a specimen that has been grown quickly from the bud, has a straight, stout stem, with a well-balanced head at one end and a nice lot of fibrous roots at the other.

Much ink has been used over the matter of planting, which, after all, is a simple matter. If the orchard is a new one let the trees stand 30ft. apart in equilateral triangles, and in all cases begin by taking off the turf where the tree is to go in a circle 5ft. across. Place this on the side, remove the top spit of soil a foot deep, and break up the subsoil underneath. Cut up the turf that was removed from the surface, spread it over the subsoil with a little of the top soil that was taken out, tread it down, and drive in the stake. A good stake that will last as long as the tree needs support is desirable, and sawn deal stakes, 7ft. long, about 2½in. square, pointed at one end, and creosoted, answer the purpose well. If the above method is adopted there will be no fear of planting too deeply, and the soil should be mounded up a little above the level of the surrounding ground to allow for sinking. After time has been allowed for the trees to settle down they should be firmly fastened to the stakes, and if stock has access to the orchard some kind of fencing will be required. Guards of timber may be employed, but they are cumbersome and expensive, and in many ways not so good as one of the light, strong wire guards that are sold for the purpose.

One point I would emphasise—do not let the grass grow up to within 2ft. of the stem of the trees for the first few years, but keep the surface soil hoed from time to time. I have made experiments in respect of this point, and have trees planted three years ago, some with the turf buried and others where the turf was laid back over the roots. To-day the heads of the former are almost as big again as those of the latter, which fact supports the contention that turf over the roots is detrimental to the quick development of a newly-planted standard.

In the choice of varieties much, of course, depends on the requirements of the establishment, but for orchard work it is always well to consider the constitution and vigour of the tree. Above everything in the orchard you want trees that will grow, and varieties that have no capacity for making good heads are out of place in an orchard. In most establishments the high-class dessert apples of not very strong constitution can be accommodated in the garden, but the orchard is the place for the all-round utility apples like Bramley's Seedling, Newton's Wonder, Blenheim Pippin, Lord Derby, and others which can be depended upon to make fine trees. Knowledge of the growing habits of varieties is very desirable when planting in orchards, and, as a case in point, Lane's Prince Albert is one of the best culinary apples we have for growing in the garden as a bush, but it is unsuitable for an orchard standard because it does not make a good head. The same remark applies to Stirling Castle and several other varieties; and, further, I would say, have no varieties in the orchard which show a predisposition to canker. Would that some scientific expert could find a remedy for this evil, which is the bane of the apple grower, but it is not forthcoming, and the only thing is to discard any variety, no matter how good it may be, in orchard planting, if the tree has a reputation for being liable to canker.

A word about pruning, of course; but what shall I say? Everybody agrees that a young standard tree should be pruned after it is planted for the purpose of starting it into growth and forming a good head, but when should it be done? Should the leading shoots on the young tree be shortened back, say, in March or early April following the planting, or should the work be deferred till a year later? I know this is opening up an old wound of contention amongst gardeners, and whichever way I advise I know someone will disagree with me, therefore I will only say that, as the result of my experience, supported by experiments I have made to test the point, better growth and stouter heads are, as a rule, obtained on standard trees that are left for a year before being pruned than if the pruning is done the same season as the planting. I am aware, of course, that very much depends on the season, but we never know what kind of a season we are going to have in this country, and I know of several orchards now in which trees planted last winter were shortened back in the early spring, and they have not made an inch of new growth. Probably they would have done so had the season been better, but is the risk worth taking considering that if the trees are left for a year after planting they become established at the root, and good growth follows the pruning in the next season, no matter whether the weather is wet or dry. H.

Lobelia cardinalis.—As they have a strong dislike to the wet and damp of our winters, it is necessary in many gardens to lift the roots of herbaceous lobelias and store them in cold frames. They delight in a moist position during the summer and autumn, yet must be kept dry in the winter. Water settles in the space caused by the removal of the flower spike, and thus sets up a general decay; so as to prevent loss, it is safest to give the roots the required protection.—E. C. Pooley.

AMONG THE ALPINE FLOWERS.

As we look upon the garden now we think of the passing year as one of the most wonderful for lovers of flowers. It has been a strangely chequered one, despite its sunshine and brilliancy. To the gardener it has brought much tribulation amid all its glory, and drought has deprived him of many of his wonted pleasures and delights. Yet it has been a season of exceptional beauty, and now that October has more than dawned we are glad that we have seen a season such as this in the garden.

It gives us now many sights of wondrous glory, especially in the autumn tints of tree, shrub, and border and alpine flower. It is but seldom that we see these under such happy auspices, and the gold and the russet and the crimson of the dying leaves seem more brilliant than is their wont as we study them in the clear sunshine of the autumn. To these are added the flowers of the time and those of another season as well; for the plants of summer, and even of spring, have been enticed to bloom in the days of October, and help to give us pleasure in company with their sisters of the later months. Very beautiful are many of these now, and we can welcome their bloom and that of their allies of October.

Lady Larpent's Leadwort.

It must have been an admirer of alliteration who dowered this plant with its popular name, which assuredly appeals to us more than Plumbago Larpentæ, the botanical designation under which it is yet best known. Still happier does it seem to us when we compare it with that of Ceratostigma plumbaginoides, which, on the highest authority, is the correct scientific appellation we are to bestow upon it. But Lady Larpent's Leadwort it will remain to many, and those who wish to commend it to the amateur will do well to eschew the name of Ceratostigma plumbaginoides, with all its uncouthness and difficulty.

I have probably spoken of it before, but I cannot allow it to go unhonoured at the present time, as seldom, if ever, have I seen it with such lovely autumn colouring as now. It is yet in bloom, and the flowers, rather like those of the old Plumbago capensis, a charming greenhouse or conservatory plant, but darker, are exquisite on a sunny rockery, such as the plant loves. But the green leaves of a month ago have assumed the most lovely colouring of red or crimson—although red conveys too dull an impression to indicate the tint we mean it to convey. One loves to linger by the plant in passing, and to wish that such a time would last still longer, so that we might the more admire this charming leadwort. It likes a dry soil and a warm place, coming too late in many gardens to be worth growing away from the sun.

Geranium lancastriense.

One must also venture to speak once more of a flower which has had its praises uttered before now. This is Geranium lancastriense, but on this occasion it is brought forward because of its autumn colouring. Deeper in its red tints than the leadwort, it is very fine at present, and when, as there is on one or two plants, a pink flower heightens the charm of this little geranium, not six inches high, with its finely-divided leaves and its fine colouring, it gives us inexpressible pleasure indeed. I have a considerable number, and of these the finest coloured are those on the poorest, hardest, and stoniest soil in the rock garden. This it likes, and the preference is not to be wondered at, seeing that it is a sea-coast plant.

The Double Red Sun Rose.

Another old plant which is proving its high value in a season like this is the old double red sun rose, or helianthemum, known long ago as H. amabile or venustum fl. pl., but called by other names now, Mrs. C. W. Earle being among the most popular of these. I expect this is because it is the one that talented lady speaks of in her "Pot Pourri from a Surrey Garden," in which she says: "I have a double-flowered scarlet rock-rose, not figured in any of my books, and which I have rarely seen in gardens. It flowers persistently for many months." This little sun rose is a charming thing and is seldom out of bloom from the time it begins, about the end of May or beginning of June. A fine October seems to give it a new lease of beauty, and it is fuller of flower than I have ever seen it at this time of the year.

Crocus Boryi.

This seems to be flowering earlier than usual with me this year, although I regret that I cannot find any record of its previous blossoming period in my note-book. Its lateness renders it a species which should be sheltered from the weather we usually experience; but this season is favourable to these autumnal crocuses. This is a very charming little one, with white flowers, my form having a pencilling of lilac at the base of the exterior, this harmonising well with the white segments. The interior is altogether white, with white anthers and handsome fine scarlet stigmata. This is one of the gems of the genus and considered less hardy than some. Carpeted by a low mossy saxifrage it stand well here.

Other Flowers.

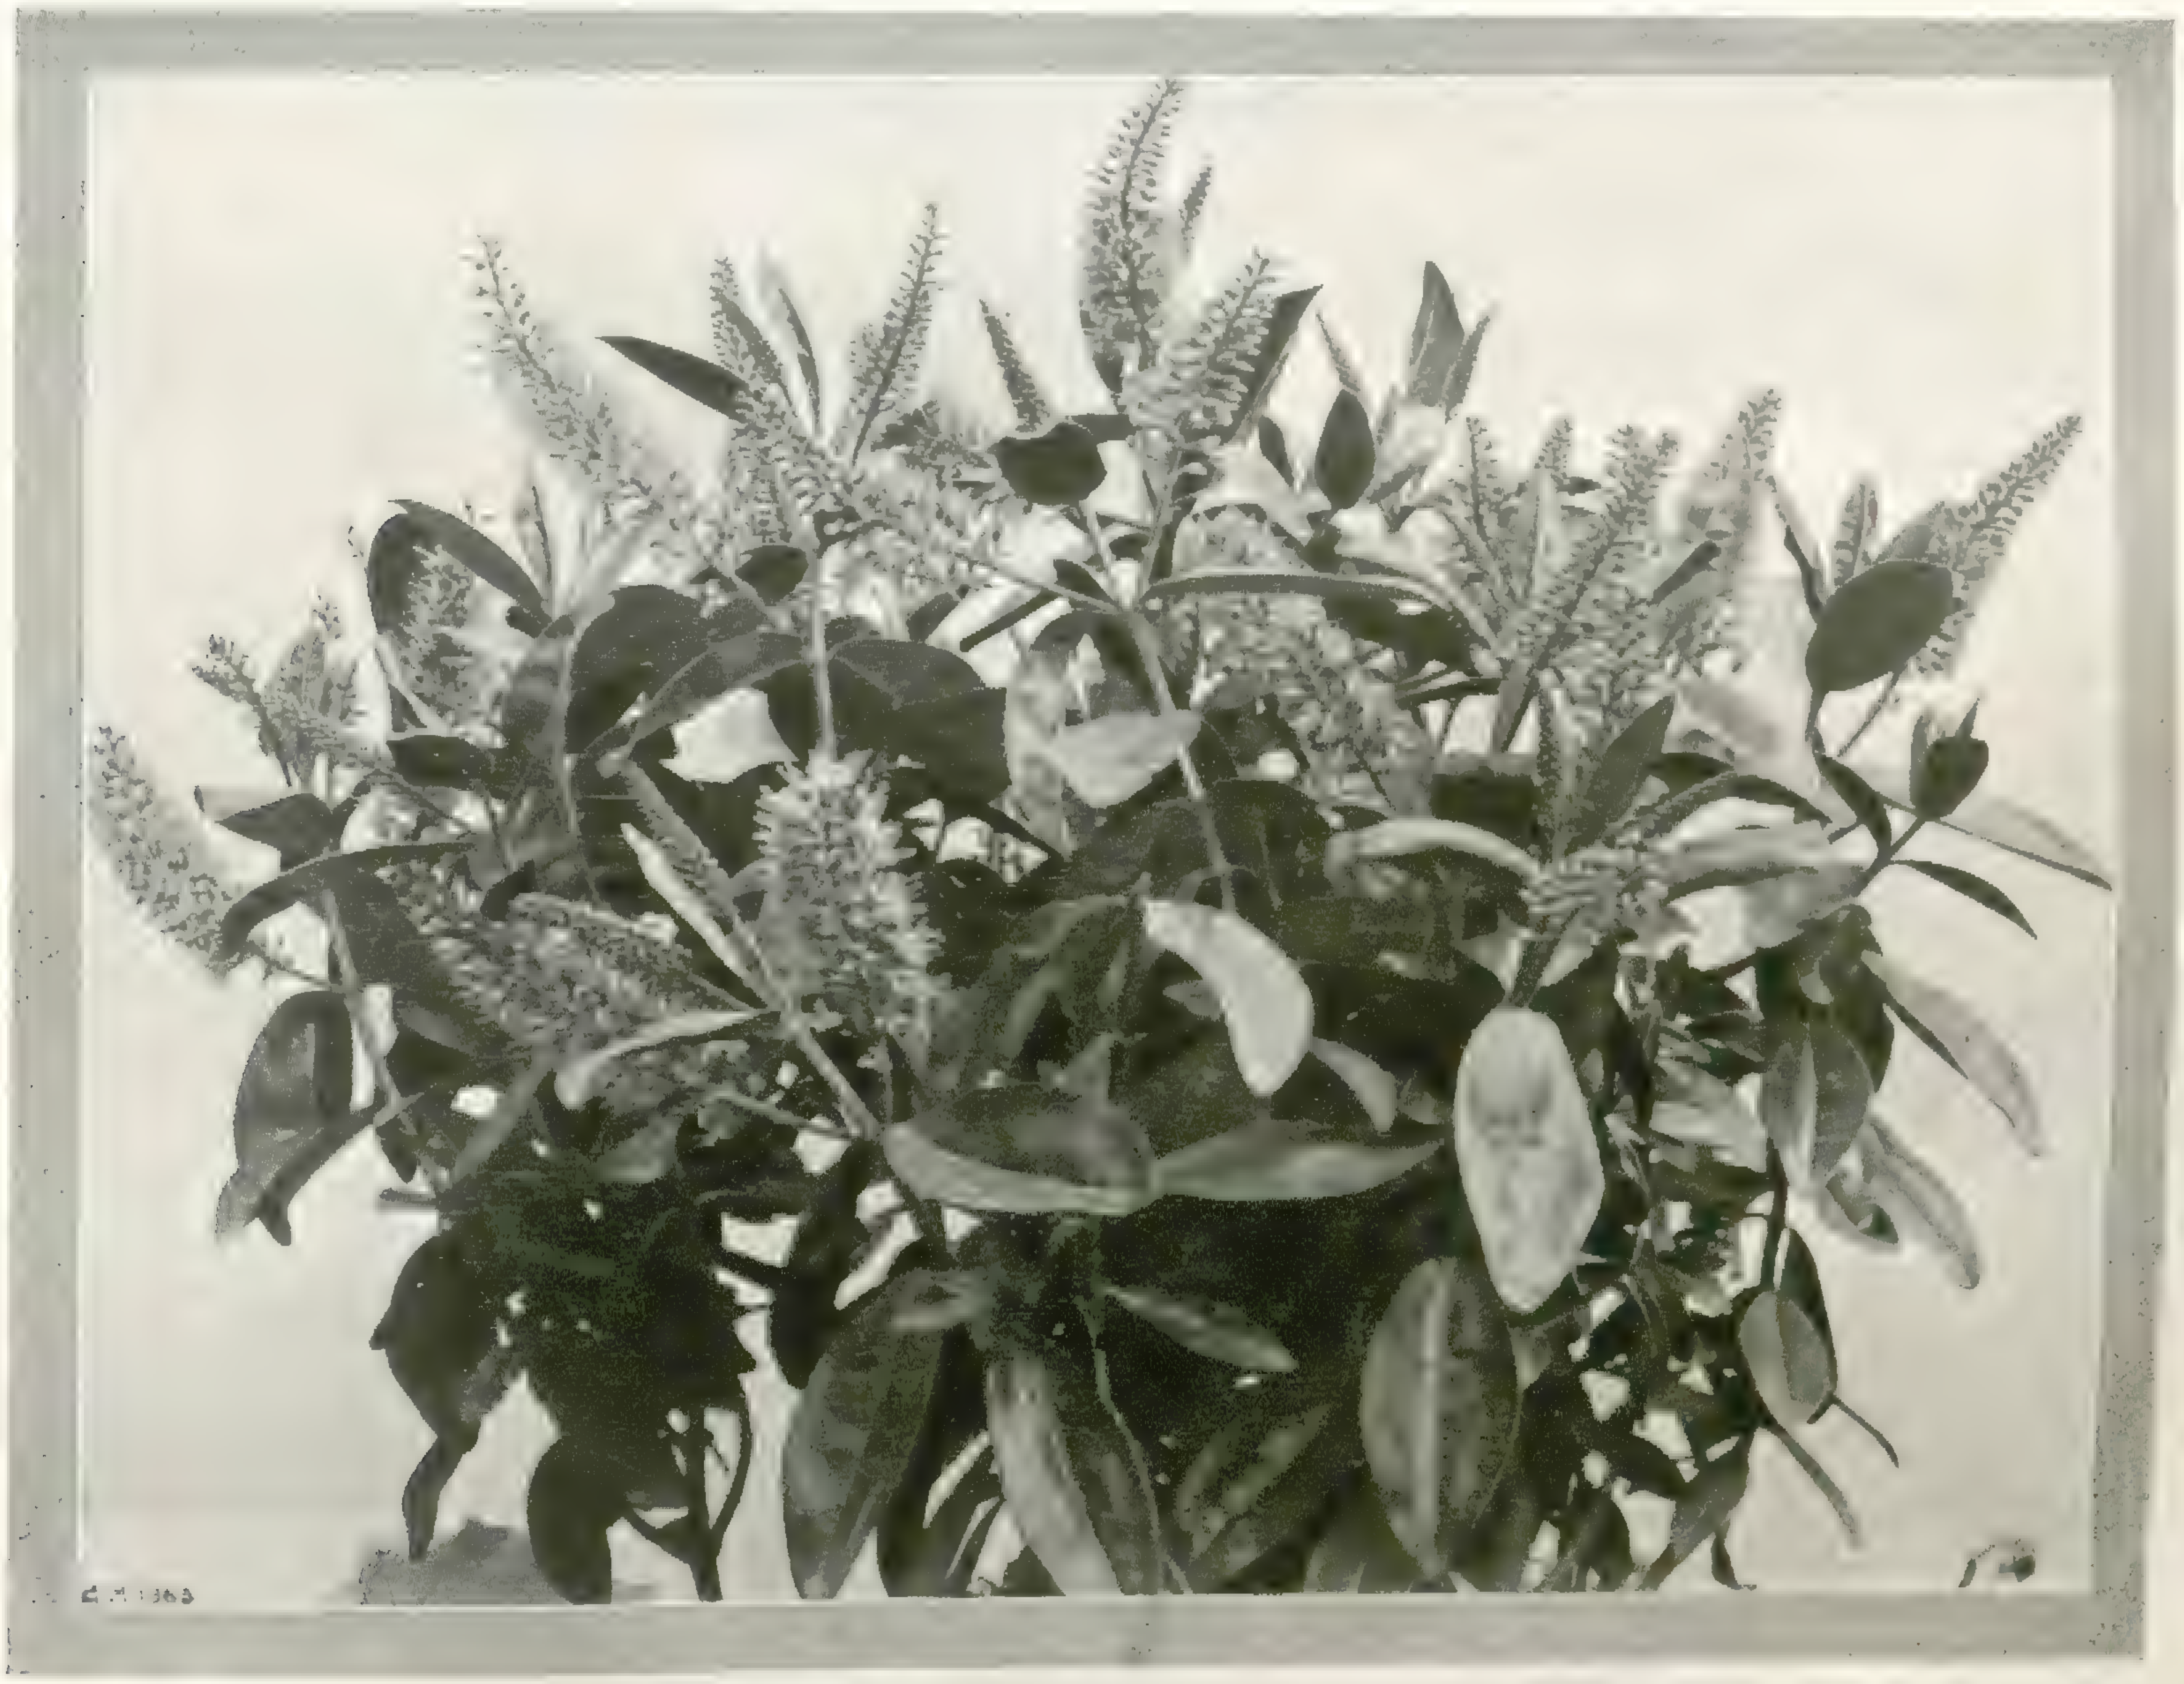
There are other crocus species—C. iridiflorus, C. pulchellus, and C. speciosus, with C. zonatus and C. asturicus, being among the most ornamental of these fine flowers. A few meadow saffrons there are also, but they look coarse compared with the delicate loveliness of the crocuses. A considerable number of erodiums also show their enjoyment of a dry season, and I have never really appreciated the worth of these plants for a sunny place in the poorest of soil until now. The little Origanum hybridum is yet in flower; there are several of the giant thrifts, such as Armeria plantaginea; a few hypericums, like H. fragile, H. coris, H. reptans, H. calycinum, and a few of the taller species. Oxalises valdiviana and corniculata yet give flowers; anthemises and achilleas adorn their allotted places with silvery leaves and white flowers; as do dwarf campanulas, such as C. garganica, C. hirsuta, some of the carpatica varieties, and forms of C. rotundifolia and others. Some of the alpine pinks have taken a fresh lease of beauty, and are giving us beautiful flowers. Even the rock madwort, Alyssum saxatile, gives us a sprinkling of gold, and A. sinuum accompanies it on the rockeries. Heaths of several kinds are yet in perfection; and, go where we may, we are always coming upon some little bit of beauty, such as we find under a bush of the Japanese rose, where a little colony of Cyclamen neapolitanum has sent up for many weeks its white or crimson flowers of the utmost beauty. Truly, we are happy in having these flowers to keep us from feeling that the winter is at hand, and to make us realise that our season of enjoyment is not bounded by the limits of a month or two, but extends over the greater part of the year.

S. Arnott.

VERONICA VEITCHI.

Within the past two decades our gardens have been enriched by a considerable number of shrubby veronicas belonging to the section represented by that fine hybrid known as V. Andersoni, and of much value from the decorative point of view. Unfortunately, they have not proved sufficiently hardy to pass through an English winter of moderate severity without receiving more or less injury, except in the more favoured districts. In the southern and western counties of England and the warmer parts of Ireland they grow vigorously, and, except in severe winters they do not suffer materially, with the result that, in many gardens, may be seen comparatively large specimens that throughout the summer and autumn months are objects of great beauty. Trained to the south side of a wall or planted in positions where the conditions are favourable to the ripening of the wood, and the plants receive some amount of shelter during the colder months, these veronicas survive winters that are not very severe, and attain a considerable size in gardens situated some distance to the north of London. They may have the more tender parts of the growths cut back by the frosts, but this is not a matter of so much consequence, for when pruned rather hard at the close of the winter they start freely into growth under the influence of the genial temperature and warm showers characteristic of the spring season. It is, indeed, surprising how quickly they recuperate and yield again of their attractive flowers. In severe winters they will be killed in many gardens, but a fresh stock can be readily raised from cuttings, and where they are employed for decorative purposes under glass some of the larger plants can be utilised in filling gaps caused by the frost.

The number of varieties belonging to this section is considerable, and many of them possess much merit, but we do not know one that is equal in value to the fine variety which Messrs. R. Veitch and Son, of Exeter, have submitted to public notice under the name of Veronica Veitchi. It has been shown at two of the meetings held by the Royal Horticultural Society since the close of the summer, and on both occasions it attracted much attention from the visitors who are interested in shrubs that are specially adapted to kind climates. The plant has ample glossy-green foliage, and is free branching, and soon grows into bushy specimens that bristle with spikes during the summer and autumn months. From the illustration given herewith a good idea will be obtained of the habit of the plant and profusion with which the rich blue flowers are produced, but to be able to form an idea of the effectiveness of V. Veitchi one had need to make the acquaintance of the fine specimens with a height of six or more feet, and a proportionate diameter, that may be seen growing in the open in Devonshire.



VERONICA VEITCHI.

A beautiful variety of shrubby habit, and bearing spikes of rich blue flowers, introduced by Messrs. R. Veitch and Son.

Cucumbers.—Keep the temperature of the cucumber house as nearly 70 degrees as possible; a few degrees higher, with sunshine, will do no harm, but do not let it run up too high with fire-heat or the growths will become weakly. Keep the temperature at 65 to 68 degrees at night, and well damp all dry places. Top dress with rich material frequently, and fumigate about every ten days. Cut all fruits as soon as of sufficient size, as nothing so taxes the plants as fruits allowed to become too large.—W. A. Cook, Leonardslee Gardens.

MESSRS. E. WEBB AND SONS SEED TRIAL GROUNDS.

Notwithstanding the frequent assertion that the climate of Great Britain is too fickle to enable us to grow our own supplies of garden seeds, we have many seed farms and trial grounds in the country, and the part they play in the advancement and extension of horticulture is of far-reaching importance. It may be claimed that nowhere has the work of improvement by selection and cross-fertilisation of vegetables and flowers been carried on with greater care or more marked success than in the trial and experimental grounds of the leading firms in our own land.

The firm of Messrs. E. Webb and Sons, Wordsley, has long held a foremost position among the largest and best seedsmen of Britain, and their extensive seed farms at Kinver not only constitute an important industry in the district, but exercise an influence on British horticulture that cannot be hastily measured or valued. Every gardener abroad, as well as at home, knows something of the work accomplished by Messrs. Webb and Sons in the raising and introduction to commerce of improved types and varieties of flowers and vegetables, but who shall estimate the amount of careful study and painstaking labour that has been involved to obtain the results we all appreciate?

A little insight into the labour expended and care exercised was afforded on the occasion of a visit to the Kinver Seed Farms during last summer, and most enjoyable and interesting the visit proved to be. Kinver is situated in most delightful country, amid natural scenery over which one might wax eloquent, but with so much to see we could only enjoy the scene for a brief spell as we drove toward the farm, and again cast lingering glances around as we left in the evening. The Kinver estate extends to some two thousand acres. The garden seed trials are conducted in well-arranged grounds many acres in extent, situated on an open hillside. Immediately on entering these grounds one comes upon long borders of herbaceous plants on either side a broad walk leading down to the office. Here were flowering profusely, despite the long-continued drought, great masses of delphiniums in every shade of blue and purple, gay gaillardias, golden coreopsis, phloxes, both white and coloured. The plants were all raised from the firm's own strains of seed, and their robust growth afforded a useful object-lesson on the advantage of seedlings over plants propagated by cuttings or division in a season of excessive heat and drought. A surprise awaited us in the great breadth of carnations which were growing with wonderful vigour, and flowering most profusely. They represented Webb's Imperial Strain, and there were yellow-ground and white-ground fancies and picotees, yellow selfs, and selfs of every other shade of colour, the quality over all being of a very high standard. Two or three bedding nasturtiums were very fine, Bedding Gem being one of the neatest and brightest scarlets we have seen. Meteor, crimson, was very rich, while Queen of Tom Thumbs was interesting on account of its prettily mottled foliage. Eschscholtzia Carmine King was of a lovely colour and good habit, other good varieties being Buttercup, small, but very free-flowering; Golden West, with orange centre and butter-yellow margin, this being a new and pleasing form; Mikado, deep mahogany; and Royal Rose completed a set of quite distinct and very beautiful annuals.

Dimorphotheca aurantiaca, the plant that has made such remarkable strides in popularity of late was in full bloom. Its chaste form and rich glowing orange gold colour make this one of the finest of all annuals, and it is small wonder that the demand for seed is rapidly increasing.

To mention all the charming flowers seen, and to furnish even brief descriptions of the particular merits of Messrs. Webb's strains would be to practically reproduce the firm's catalogue, for everything stocked is subjected to trial on the grounds, and it may be added that there was ample evidence that only varieties of the highest merit have a chance here. I must, however, pay tribute to the excellence of the pentstemons. The stock was derived from seed of Mr. E. Beckett's superb collection, and the doctrine of "Like produces like" has been well borne out here, for certainly the great breadths of seedling pentstemons in all colours were of handsome form and size, and for the ordinary mixed border nothing finer could be desired than a batch of this strain which, by the way, bears the name of Crown Jewel pentstemon. Almost as beautiful as the pentstemons were the antirrhinums, which embraced shades and combinations of colour in such variety as to baffle any attempt at description. In height they ranged from Tom Thumbs about eight or nine inches high, to giants with a stature exceeding three feet, all compact and erect in habit. For those who prefer separate colours, distinct varieties are available. The trials of stocks and asters were on an extensive scale, Admiration stock being wonderfully fine in rose, flesh, white, and crimson. Never have I seen a grander show of poppies than at Kinver. Shirleys in every conceivable shade of pink, rose, scarlet, and crimson; Magnet poppies of immense size and rich colours; Malmaison poppies, carrying double flowers, bearing close resemblance to Malmaison carnations, all full in bloom, the long beds being masses of shimmering loveliness.

The clarkias, godetias, larkspurs, especially the dwarf double forms, all deserve detailed description, but alas! my space is not unlimited, and I must, perforce, leave the purely decorative subjects to deal with the equally important, if less attractive, vegetables that are so well and largely grown in these extensive seed grounds.

Culinary peas are something more than a mere item in the trials at Kinver, and must, in fact, be accounted a leading feature. From dwarfest to tallest, earliest to latest, smooth, wrinkled, straight-podded and curved, peas to meet all requirements and satisfy everybody's demands were growing apace and bearing heavily. The collection was well worthy an afternoon's attention, and, indeed, it required some hours to closely inspect and compare the great number of varieties represented in the trials. Among the dwarf earlies, which, although past at the time of my visit, showed heavy crops of seed, the new Dwarf Gem was one that had rendered a good account of itself. It grows but a foot high, and bears fine large pods for a first early. Little Marvel is another of the same class, specially suitable for pot culture. Webb's New Pioneer is one of the earliest of the wrinkled marrowfats. Growing about a yard high, the sturdy plants bear an abundance of straight-podded peas of capital size and beautiful appearance. The variety has won high praise from gardeners up and down the country, and is certainly a pea of more than ordinary good quality. Among the peas that are particularly well adapted for exhibition purposes, Defiance Marrowfat, introduced last year, has proved to be an acquisition, the pods being long, broad, and of beautiful quality. A dish of Webb's New Model would be a strong point in any collection of vegetables. It as closely approaches perfection as one can well expect to see, and its flavour is as good as its appearance. Stourbridge Marrow has been a sufficient length of time in commerce now to have made a name for itself, and it will be a long while yet before its popularity wanes. The long rows on the trial grounds were highly attractive. Attaining a height of five feet or rather more, the haulm is strong and vigorous, and the pods, while fine enough for the show table, are borne with a freedom that is calculated to delight the heart of the market-grower.

Another remarkable cropper is Senator, the variety that realised the sensational price of £44 per acre at Kidderminster in July last. I have for a long period felt that it would pay our market men to take greater pains to obtain the best varieties of peas, and the record price obtained by Senator should show that this is a pea to grow for profit. Many another good pea was seen and taken note of as we passed up and down between the rows, and let it be added the large number of varieties are not merely peas under different names, but are all possessed of distinctive characteristics and points of merit that render them useful, any variety that falls short of these conditions being unhesitatingly discarded. Nor is it peas alone that are thus carefully handled and scientifically bred, but every class of vegetable that is grown by the British gardener receives close attention. Thus, did space permit, I could write at length of the high-class onions, the tempting tomatoes, solid-hearted cabbages, and all the other subjects that came under notice during my tour of inspection, but readers of the Gardeners' Magazine have from time to time seen illustrations, and read descriptions of the splendid specimens exhibited by the firm at the leading shows. It may, however, be added that the trial crops bore evidence that the whole of the stocks are wonderfully true to type and quality.

In one big field where the potato trials are conducted there were somewhere between seventy and eighty varieties, and although the summer's drought was very severe, many of them were doing remarkably well. It was interesting to see that Guardian, Goldfinder, Chieftain, and Colonist, which have rendered good accounts of themselves on the exhibition table, were growing well, and appeared to be absolutely free from any sign of disease. As generally known, Messrs. Webb and Sons grow farm seeds very extensively, and have been responsible for the introduction of some of the finest barleys, oats, and wheats in cultivation.

Small wonder that the head offices and store houses are huge buildings, and that a glance inside any one of the departments is to witness a scene of remarkable activity. The business of Messrs. Webb and Sons is, indeed, a large one, and, as mentioned at the commencement, has an important bearing on the welfare of the locality, and upon British horticulture.

Visitor.

LAVENDER GROWING.

The following interesting account of the lavender industry we reprint from the October issue of the "Journal" of the Board of Agriculture:

Lavender, which was introduced into England from the South of Europe in the sixteenth century, is grown commercially in a few districts in England where conditions have proved to be especially suitable to its cultivation. The principal lavender plantations are to be found in the neighbourhood of Mitcham, Carshalton, and Beddington, in Surrey, and at Hitchin and Canterbury. At each of these places the industry has been carried on for many years, and a local reputation for their lavender production has been established, which is no doubt a valuable asset. Recently its cultivation has been extended to Dorsetshire, where a somewhat large area at Broadstone has been devoted to it in conjunction with some other similar plants.

Although it is not improbable that there are many other districts where the crop could be grown with success, the difficulty of disposing of any large quantity of the produce in places where no still exists must be borne in mind. Distillers are often loth to take produce from a distance, owing to the fact that in order to get the best results distillation should take place immediately after harvesting. On the other hand, it may be pointed out that most large towns provide a fair market for bunches of lavender flowers.

The lavender plant is probably more dependent on climate than soil, though a light loam overlying chalk and a sunny sheltered position sloping to the south or south-west are perhaps most favourable. It is successfully grown at Hitchin on a light gravelly subsoil. Lavender is indigenous on the hills bordering on the Mediterranean, and conditions which closely reproduce those of its native habitat are necessary for its successful cultivation. As regards soil, good natural drainage, a light, fairly rich soil, and a warm position are essential, while a mild winter, with a low rainfall, followed by a warm, dry summer, favours a good crop, and, what is equally important, a high-quality oil.

A naturally sheltered position should be chosen if possible, as the plants may be injured by high winds in summer; but the artificial shelter of hedges or walls is not usually recommended. The plant is very liable to injury by frost.

The ground should be thoroughly cleaned before planting by being allowed to lie fallow, the weeds being collected and burnt, and the soil ploughed and cross-ploughed to produce a good tilth. A medium dressing of dung may be given at the same time.

Cuttings should be taken from established plants in the summer from June onwards, and struck in prepared beds, where they can be watered during dry weather. They should be put in 3in. or 4in. apart. The old custom of tearing off the woody branches of the plant and planting them thickly in trenches, though somewhat quicker in its results, is a bad one, as cuttings taken in this way are said to be more liable to attacks of fungus disease.

The young plants will be ready to plant out in their permanent positions in the following spring about May, when they should be dibbled in about 4ft. apart in rows and 6ft. between the rows. At this rate, 2,000 will be required per acre, and if they have to be purchased the cost may be 16s. per 100, or less. After the ground has been stocked, the grower would provide new plants by striking cuttings himself.

In the first year the plants should be cut back to prevent them flowering; in the third and fourth years they will be in their prime; and after the fifth year they should be dug up and burnt. Practice in this respect differs. At Hitchin they are taken up at the end of the third year. In making a new plantation, therefore, planting should be extended over several years, so that too large an area may not have to be grubbed up at once. After the lavender plants have been cleared out, some other crop, such as potatoes, should be grown for a year or two before the land is again planted with lavender.

The time of harvesting will depend on the character of the season, but it is usually early in August. Mr. F. Ransom, writing in the "Pharmaceutical Journal," states that the earliest season recorded by him was in 1868, when it commenced on July 17, while the latest was in 1894, when it was deferred till September 3.

The same writer estimates the average yield of oil at 12lb. per acre if the whole area under cultivation, including that devoted to cuttings and to the first year's growth, is taken into consideration. But from 15lb. up to as much as 30lb. of oil may be obtained in a favourable season when the plants are in their prime.

The value of the oil varies according to quality, demand, and other seasonal conditions. From 100s. per lb. thirty years ago it fell to 20s. to 30s. per lb., but during the present year the price has risen, and 40s. per lb. may be given as the current wholesale price.

Apart from growing for oil, which is not advisable unless a lavender distillery exists in the neighbourhood, the plant may be grown for its dried flowers. There is a limited sale for these at Covent Garden, while they may also be sold locally. It is in the latter direction that small holders may be able to dispose of the crop from a small area. Caution, however, is desirable, as the normal demand is not large.

The lavender plant is very subject to a fungus disease, which attacks the root and stem; indeed, the decline in cultivation which took place some years ago is said to be due to this cause, with the result that large quantities of foreign oil were imported, and to some extent supplanted the home product.

In view of the liability of the plant to this disease, it is very desirable (1) to root up and burn the old plants in order to destroy any fungus spores or mycelium that may be present, and (2) after sterilising the soil with quicklime to plant the ground with another crop for a year or two.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

At some shows fairly liberal prizes and several classes are provided for incurved blooms, but at many others scanty encouragement is given them. Years ago the principal class for cut blooms was generally the one in which equal numbers of Japanese and incurved blooms were shown, and, as a rule, the keenest interest was taken in the latter—at least, by cultivators. Then a time came when the incurved section was given the cold shoulder as it were, and they were not grown as extensively. Undoubtedly, in those days the cultivator had to possess much ability in order to grow perfect blooms. Nearly all the varieties grown were very refined, but one cannot say as much of some of the blooms classed as incurved at the present time.

Groups of plants are popular at present-day shows, and I certainly think that a few well-grown incurved varieties associated with the Japanese enhances the beauty of such groups, both when arranged in competition and also in the conservatory at home. Buds of many varieties "taken" at the end of August and during the first ten days of September develop into very refined flowers, and I would urge the inexperienced cultivator to take all possible care of such buds. The wood on which buds show as late as this in the season is rarely too ripe, and so every advantage must be taken to get it ripe before the plants are put under glass at the end of September.

The early buds of Japanese varieties will now be swelling rapidly if the stems immediately below them have thickened well. If, however, the buds are rather hard, syringing on fine days, if not done very late in the afternoon, will assist the swelling.

Sparrows will peck out the centres of forward buds where these birds are numerous and woods are near. I have seen beautiful fat buds partially spoiled by them.

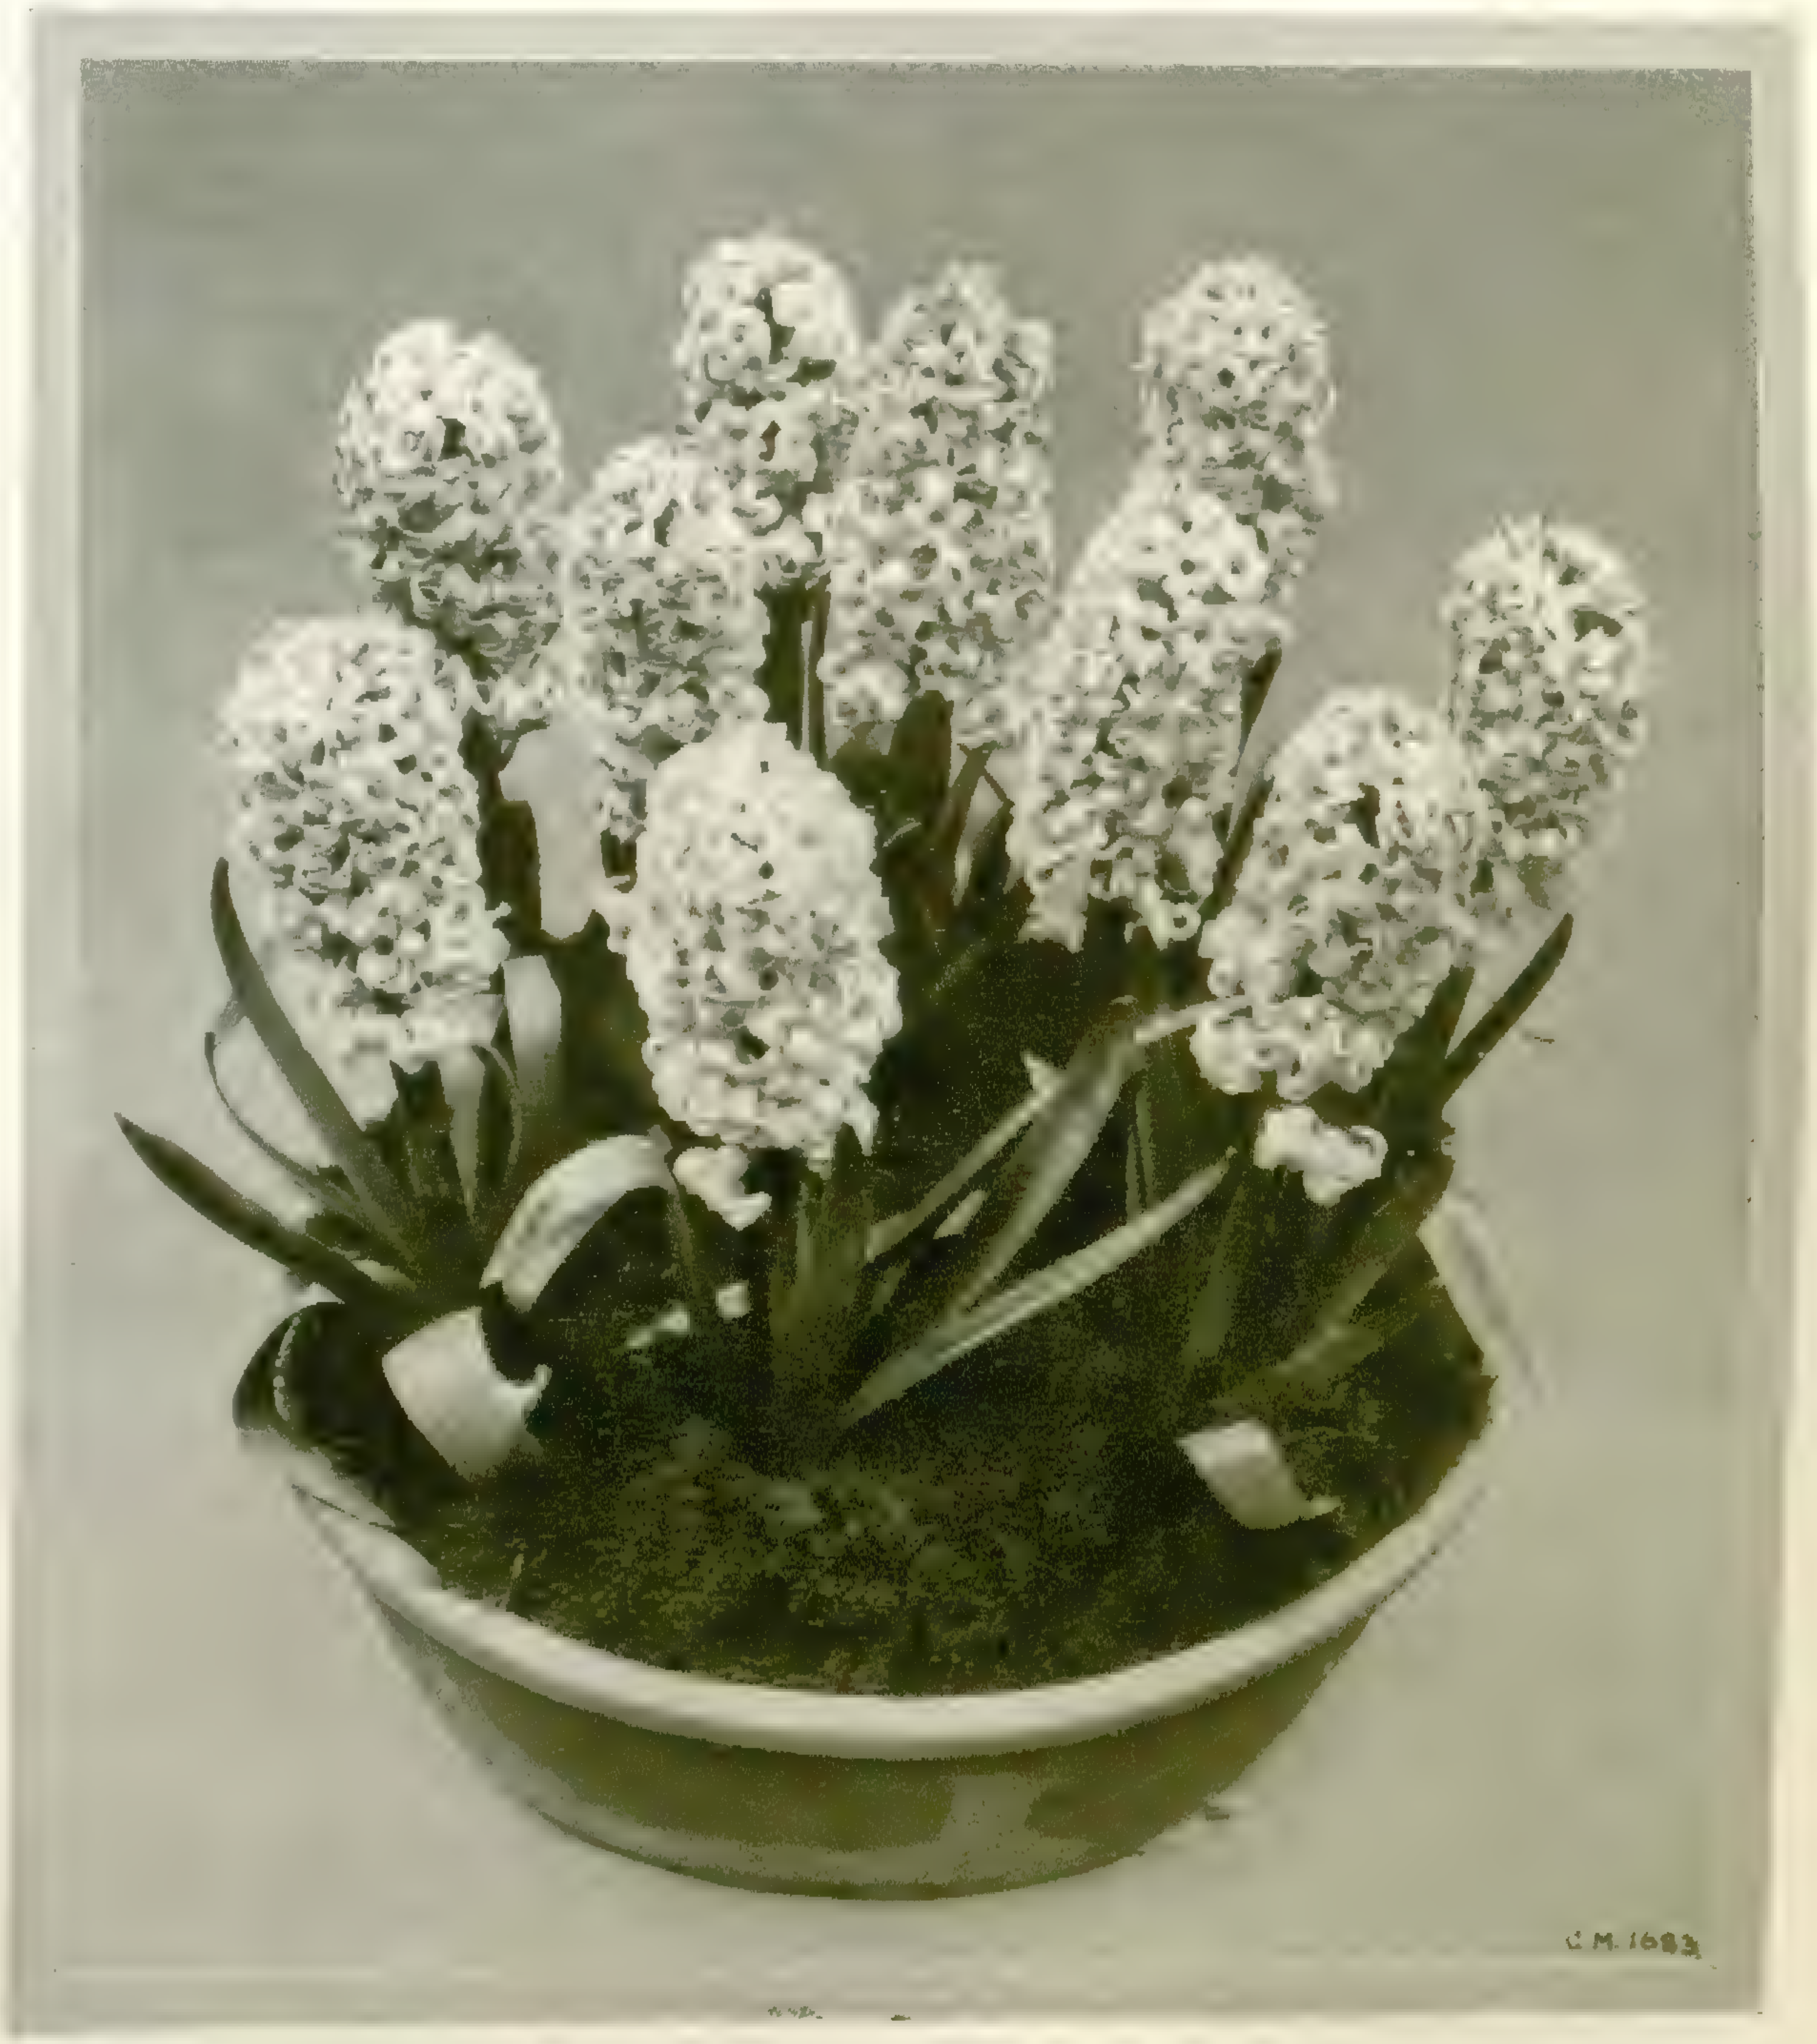
There is no doubt about the real popularity of the single-flowered varieties, and the lovely varieties recently introduced have compelled the admiration of growers and public alike. Like the blooms of the incurved varieties, those of the single are better, and in every way more refined, when the buds are "taken" rather late than very early. Full development soon follows the showing of colour of the petals. The plants grown for flowering at Christmas are often placed behind walls and fences in order to retard the opening of the blooms. Much better results follow when they are exposed to all the sunshine possible until the wood has matured and the buds formed. The plants are then in a healthy condition, and will not only withstand a little retarding in a very cool house later on, but be in a more fit state to be benefited by judicious feeding.

Geo. Garner.

FRUIT GROWING.—Full instructions as to planting, pruning, and management of fruit trees are given in PRACTICAL FRUIT GROWING (Ninth Edition) —a gold medal essay by John Wright, V.M.H.—price 1s., or by post 1s. 3d. from GARDENERS' MAGAZINE Office, 148 and 149, Aldersgate Street, London.

HYACINTH CITY OF HAARLEM.

Yellow hyacinths are by no means numerous, and in general cultivation in this country very few of them are known. The Dutch growers recognise about two dozen single-flowered yellow varieties, and these include some which are yellow only when one's imagination has been hard worked. King of the Yellows, Obélisque, MacMahon, Bird of Paradise, General Butler, Ida, and Vainqueur are among those with which home growers are more or less familiar, but yellow hyacinths are not popular, chiefly because they lack the robustness and vigour of the white and blue varieties, and the colouring is mostly a very long way behind the general conception of yellow. The best yellow hyacinth that has come under our notice either at home or in Holland is City of Haarlem, a variety that was grandly shown by Messrs. Ant. Roozen and Sons at the great bulb show held in Haarlem in March, 1905, and again at the Jubilee Show at Haarlem in 1910. The present illustration of the variety represents it as grown by Mr. Edwin Beckett, V.M.H., gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Herts, and the pan depicted was one of the six remarkably fine specimens with which Mr. Beckett won first prize at the Bulb Show held in March last by the Royal Horticultural Society, when hyacinths were staged in finer condition than for some years past.



HYACINTH CITY OF HAARLEM.

A beautiful variety, with pale yellow flowers, and properly regarded as the best in its colour group.

WORK FOR THE WEEK.

ORCHIDS.

SEASONABLE NOTES.—The conditions prevailing outside necessitates the practice of what is termed the winter treatment in the different divisions of the orchid houses. In the first place, the temperature in the various departments should be gradually reduced to the minimum degree. This can be explained by a general statement that the temperature of each division may be reduced by about five degrees. This is generally advised because of the fluctuations of the outside conditions, and owing to the subdued light very little advantage is derived by the plants from high temperature. To avoid fluctuations of temperature is a most desirable aim, but when excessive cold weather prevails, a fall of five degrees, or even more, from the normal, will produce no ill effect. We consider it is better to permit the temperature to fall, within a reasonable limit, than to resort to excessive artificial heat to maintain the thermometer at the usual level. But with a lower temperature care must be taken to reduce atmospheric moisture. Plants are rarely injured if dry conditions are provided during the prevalence of cold weather outside, and low readings of the thermometer inside. We make it a practice not to damp the floors, staging, etc., of our houses before the normal temperature is reached., and then only if the rise is sufficient to permit of the moisture becoming dispersed before the lower evening temperature is reached.

WATERING.—All plants that have matured, and, in the case of seedlings, those that have reached the flowering stage, will now require to be carefully attended to in respect to watering. The compost should be permitted to become dry about the roots of the plants between waterings. See that the water used is at least as warm as the atmosphere of the house. It will often be found that, after cold rains, and more frequently still with snow melting from the roof, the water in the tanks will be much colder than the atmosphere of the house. The use of such water cannot benefit the plants, and sufficient hot water should be added to raise it to the desired temperature before use.

VENTILATION.—I am afraid I am not an advocate of that free circulation of air about the plants at all times that some regard as necessary. I have a distinct recollection of a prominent horticulturist having some orchid houses erected where a penny piece was to divide the laps in the glass roof. There was no doubt about this affording free ventilation at all times; but the excessive fire heat required in winter destroyed all prospects of successful orchid culture. Ventilate whenever the outside conditions permit, and use the lower ventilators so that the air passing over the hot pipes may become warmed before reaching the plants.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

POINSETTIAS.—These valuable winter-flowering subjects are now freely developing their bracts, and will afford a cheerful display in the intermediate stove during the dull season of winter, when such brilliance is more than welcome. It should be remembered that poinsettias are practically dormant after the bracts have fully developed, so that extreme care in watering is most essential at this stage, excessive applications being liable to cause considerable loss of foliage, and reduce the value of the plants. The temperature of the house in which they are flowering may be reduced to 50 deg., and no serious damage is done if reduced to 45 deg., in which case, if the plants are required for house decoration, their lasting properties will be increased. In some cases poinsettias have to be used as cut flowers, and when this is so, immediately they are cut the wounded part must be sealed up by some such treatment as dipping the stems into hot water, plunging them into powdered charcoal, or searing the wound with a hot iron. Whichever operation is decided upon, it must be carried out before the stem loses any sap, or flagging will follow. As they finish flowering some attention must be given to ripening the wood preparatory to drying off and storing the stock in a dry position, where the temperature does not fall below 45 degrees.

GARDENIAS.—Where these plants are cultivated expressly for winter flowering, the growths will now be well set with flower buds; but from now until Christmas the flowers do not open so freely as they generally do in the early part of the New Year. I much prefer in this case to depend upon pot-grown plants, which have been liberally treated, and kept somewhat root-bound during the autumn. They should be staged at the warmest end of the stove when ready for flowering, and raised on inverted flower pots, as this encourages short-jointed lateral growths which provide successional displays of flowers. Mealy bug and brown scale are almost inseparable from gardenias, but where good results are expected one must make constant and diligent search almost daily to keep these troublesome pests at bay. An occasional fumigation and frequent syringing with an insecticide will save time in the long run.

PLUMBAGO ROSEA.—When treated as a winter flowering subject this is much appreciated. Its deep rose-pink colour is charming during daylight, and becomes even more pleasing under artificial light. The plants are now commencing to develop their flower spikes, and may be staged in a light and somewhat drier atmosphere than previously. Ventilation judiciously applied will improve the quality of the flowers by increasing the colour and enabling them to last much longer when cut. Plumbago flowers are admirably adapted for table decoration, and when tastefully associated with smilax or asparagus growths, they present a charming and elegant appearance.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

MATERIAL FOR PROTECTION.—As the cold season approaches it is necessary to have plenty of protective material in readiness to prevent losses amongst the tender subjects which have to pass through the winter outdoors. Bracken is an excellent covering for many plants, such as the gunneras, roses, or other plants requiring some light protection from frosts. Wattle hurdles are useful for breaking the wind where shrubbery borders are exposed to rough weather, especially in gardens on the sea coast where the salt winds cut the hardiest subjects. When new borders and beds are planted in such gardens it is advisable to place the hurdles in position before the shrubs are planted. A little extra work is necessary when dealing with specimen shrubs that have attained a fair size and are too large for ordinary hurdles. For these an open lattice framework should be erected on the cold side, and spruce or similar branches woven in it. The hamper frames which are used by nurserymen when sending out shrubs will be found very handy for shrubs that are not too large for the frames to cover. These should be securely fixed in the ground over the subject, and mats may be thrown over them at night.

AMARYLLIS BELLADONNA.—The past season has been an exceptionally good one for this beautiful autumn-flowering bulbous plant. There has been a grand display of magnificent spikes of flowers, which are always highly appreciated for decorative purposes. Early planting is essential for successful cultivation, but one must not expect too much from them until the plants become thoroughly established. The bulbs should be purchased and planted without delay, as their resting period is a very short one, and the sooner they are in the ground the better. An ideal position to plant the bulbs in is at the base of a south wall, in a well-drained and rich soil, burying them about six inches deep. If the selected spot should be damp, then the soil must be taken out to the depth of eighteen inches or two feet, drainage placed in the bottom of the trench, and the soil put back again, enriching it, if necessary. After planting, the border should be covered with some light protective material, such as bracken or light litter, until the bulbs are established, when it may be dispensed with. During the growing season, every encouragement should be afforded the plants to ensure healthy and vigorous foliage. Old-established plants which have worked themselves close to the surface, should be top-dressed.

CRINUMS.—A similar position to the one advised for amaryllis will be found suitable for crinums, but the bulbs must be planted from twelve to eighteen inches deep in a rich mellow loam. The foliage is extremely handsome and ornamental during the summer, and in the autumn, when the flowers appear, a striking effect is produced. C. Powelli, and its variety album, are quite hardy, and in warm localities C. Moorei may be successfully grown.

EARLY FLOWERING GLADIOLI.—These commence to grow very early, and unless protected, the young shoots, which are now pushing through the surface, will be destroyed. Bracken lightly laid over the border is a good safeguard against damage by frost. In the warmer climate of the south and south-west they pass through the winter safely without protection, but it is necessary to cover them in colder districts.—E. C. Pooley, Gnaton Gardens.

FRUITS UNDER GLASS.

EARLY VINES IN POTS.—These may now be pruned, especially if intended for starting towards the end of November; the canes will be well ripened, having enjoyed a long season of sunshine, and in order to maintain that advantage, they will, if pruned now, have a month of absolute rest, as water should be withheld except in extreme cases. As long as they remain outside they will not take much harm, but if we have a period of rain they should be taken into a cool and airy house.

PERMANENT VINES.—These will be ready for pruning within the next fortnight, so that they may have a period of rest before being started in December. The shoots should be pruned back to one good bud, or two at the most, leaving it on the upper side of the shoot for preference, as this is generally the strongest. After pruning the vines should have another good washing, and every particle of glass and wood and iron work should have a thorough cleansing with strong insecticides or petroleum and soft soap, and if it can be painted afterward, so much the better. All the top soil should be removed in case any pests should be lurking therein.

PEACH HOUSES.—The trees in the early house will by this time have shed all their leaves, and if the house is vacant the final pruning should now be done; assuming that a previous pruning took place after the removal of the fruit there will not be much wood to cut away. Remove all the growth that is not necessary either for fruiting or for balancing the tree. In many cases peach trees are not thinned enough. The shoots should not be tied in closer than six or seven inches apart, leave all the young fruiting wood possible, and cut out the long useless shoots. After pruning tie up the branches in convenient bundles, clean the wires with soft soap and petroleum, and give the glass and woodwork a thorough cleansing. Leave the ventilators open both top and bottom so that the house is kept cool and healthy. As soon as cleaning is finished proceed to tie and train the trees. Tie in the main shoots or branches first with strong tar string, and then start tying at the bottom and regulate the branches upwards, distributing them equally all over the space. This done, the surface of the border must next be dealt with. All old mulching material must be raked off, and the old surface soil pricked over with a fork lightly, and removed, its place being taken by an inch or two of fresh loam and mortar rubble, with a little bone-meal added.

THE EARLIEST FIG HOUSE should be treated on similar lines as soon as opportunity permits. I am a firm believer in proceeding with such work quite early in the season, so that there is no undue rush a little later on.—W. A. Cook, Leonardslee Gardens.

BRADFORD CHRYSANTHEMUM EXHIBITION in ST. GEORGE'S HALL, on
FRIDAY and SATURDAY, November 10th and 11th.
£50 FOR BLOOMS ON BOARDS.
Besides other good classes for open competition.
Schedules, with entry forms, post free from
H. SPENCER,
Hony. Secy.
Horton Park.

Secretary, 12, Eagle Parade, Buxton.

SCOTTISH HORTICULTURAL
ASSOCIATION.

CHRYSANTHEMUM EXHIBITION.

The Association will hold its next
GREAT CHRYSANTHEMUM EXHIBITION,
in the
WAVERLEY MARKET, EDINBURGH,
on
November 16, 17, and 18, 1911.

Copies of the Prize List, which contains all particulars as to prizes, conditions of competition, etc., may be obtained on application to the Secretary,
A. D. RICHARDSON,
19, Waverley Market,
Edinburgh.
Entries close on November 8th.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

An exhibition of considerable size was held at the Royal Horticultural Hall on Tuesday, October 24, and, though rain fell almost continuously all day, there was a good attendance of Fellows and visitors. Dahlias were present in great force, and lent splendid colouring to the general display. Trees and shrubs were brought in large numbers, but the efforts to show autumn colouring were not good, as so many of the really fine subjects were often only represented by a few small branches. Orchids were well shown, but there was only a moderate display of fruits and vegetables. Novelties were fairly numerous for the season.

FLORAL COMMITTEE.

A great exhibit of bamboos from Mr. L. R. Russell, Richmond, extended the whole length of the far side of the hall; on a bright hot day such an exhibit would have been appreciated, but as the day was a very dull one, the long stretch of bamboos did not help matters. Phyllostachys nigra, P. Castillonis, P. rubicunda, Thamnocalamus nepalense, T. Falconeri, T. gracilis, Bambusa palmata, and B. marmorea variegata were a few of the most graceful kinds in a large collection. Mr. Russell also contributed a group of berried shrubs.

Mr. Thomas Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, contributed a large group of purplish celosias, every plant a perfect pyramid of plumose florescence, capped with a cockscomb-like head.

A large and interesting exhibit, from Messrs. W. Cutbush and Son, Highgate, consisted chiefly of new hardy climbers from China; rubi and vitises were very much in evidence, but a number of the species presented were as yet unnamed, while others were apparently not fully determined. Some labelled as rubus appeared to have more relation to vitis. Clematis Armandi, Vitis heterophylla Delavayana, V. pentagona, Rubus mesogoeus, R. lasiostylus, and R. Geraldianus were conspicuous. Finely berried skimmias provided a foreground in which was set a basket of Veronica Silver Queen, a dense habited, silver-variegated form. In another group the Highgate firm put up a fine collection of Michaelmas daisies wherein such beautiful varieties as Climax, Novelty, Delight, Sirius, Ideal, and White Queen were excellent. In yet another group Messrs. W. Cutbush disposed a set of perpetual carnations, and here the outstanding variety was Goldfinch, a broad petalled rich apricot-coloured form of great distinction and beauty.

The charming little Cyclamen neapolitanum and its white form, with the tiny starry white Narcissus serotinus, autumn crocuses, kniphofias, and perennial asters came from Messrs. Barr and Son, Covent Garden.

A large exhibit of shrubs across the end of the hall, arranged by Messrs. James Veitch and Sons, Chelsea, was of great interest, as it included a number of very fine subjects, such as Lonicera nitida, a neat evergreen, with tiny shining foliage; Symphoricarpus occidentalis, covered with white berries; Berberis Thunbergi, Viburnum Awafuki, Vitis purpurea, Quercus coccinea, and Smilax caduca, all remarkable for their brilliant foliage. Gold and silver conifers, yuccas in variety, standard bays, ivies, and privets were all used in the group, while Ilex Pernyi, I. cornuta, Berberis Gagnepaini, Berberis Wilsonæ, and Ligustrum Henryi were among the newer things on view. In another group the Chelsea firm presented a bautiful batch of Nerine Fothergilli major, Begonia Mrs. Heal, and hybrid greenhouse rhododendrons in a great variety of colours.

A rare bank of brilliant colouring was provided by Messrs. T. S. Ware, Lim., Feltham. Their exhibit consisted of two parts, one of early chrysanthemums, put up in large sheaves, but a little too closely arranged; in the other half cactus and paeony-flowered dahlias were very extensively shown, and the flowers were of remarkable size and brilliance for such a late date.

Several new Michaelmas daisies from Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, Elstree, attracted a good deal of attention; one large-flowered variety named Amethyst (A.M.) is quite bright blue; Silver Queen is very graceful and thickly studded with tiny whitish flowers; Comeliness, Approval, and Profusion (A.M.) were all distinct and grandly represented by large specimens.

New nerines were finely shown by Mr. Walters, gardener to H. J. Elwes, Esq., Colesbourne, Cheltenham. These represented colouring from almost pure white to deepest crimson and maroon, and a few that especially appealed to us were the deep orange, deep maroon, a very free rosy pink form, and some of the salmon shades. Mrs. F. R. S. Balfour, pink and red (A.M.); Hon. Miss Gibbs, soft maroon (A.M.); Snowflake, white (A.M.); Mrs. Mead-Waldo, orange (A.M.), were the pick of a fine set. Mr. Elwes has been working among nerines for many years, and has added many new colours, as well as improved the form, to a useful genus of greenhouse bulbous plants.

Autumn-tinted foliage of many kinds was staged by Messrs. J. Cheal and Sons, Crawley, who showed Rhus typhinus laciniata, oaks, berberis, viburnums, etc. Messrs. Paul and Son, Cheshunt, presented autumn foliage and a collection of rose hips and fruits.

The collarette dahlias were again well shown by Mr. J. B. Riding, of Chingford, and his stands of Crown Prince, Charlotte, Bajadere, Henri Farman, Ideal, Joseph Goujon, Madam Poirier, Orphée, Gallia, and the yellow Souv. de Charbanne were very attractive. Messrs. Allwood Bros., Haywards Heath, were exhibitors of perpetual carnations, and Messrs. S. Low and Co., Enfield, had a considerable exhibit of these popular flowers.

Pæony-flowered dahlias were finely shown by Messrs. Bakers, Wolverhampton, who filled a length of table with fine colour; Mrs. Ralph Heaton, J. S. Brunton, Sunset, Red Indian, King Leopold, Germania, and Faust were a few of the best varieties.

Mr. G. Reuthe sent a small collection of hardy plants, and Messrs. Carter Page and Co., London Wall, had a large and attractive group of dahlias.

The collection of adiantums staged by Messrs. H. B. May and Sons, Edmonton, included a hundred and twenty species and varieties of these graceful and popular ferns; this was a fine collection, and included the new Glory of Nordrecht, a form of A. tenerun Farleyense, A. Birkenheadi, A. trapeziforme, A. scutum, A. Veitchi, A. Lindeni, A. elegantissima, and A. cardiochlæna.

The very pretty Cosmos White Queen, C. Rose Queen, and C. Crimson King, three fine annuals, respectively deep rose, pink, and rosy crimson were exhibited by Messrs. Dobbie and Co., Edinburgh.

Messrs. W. Wells and Co., Merstham, had a large display of chrysanthemums and carnations, and among the former they had Bronze Goacher (A.M.), the handsome light crimon Japanese variety, Mrs. R. H. Witty, the big pale yellow Japanese form named Mrs. W. Hookey, and the single Dorothy Dann; this firm's group of Japanese, single, and decorative chrysanthemums, arranged with crotons and Michaelmas daisies, was a great attraction.

Mr. James Box, Lindfield, filled one corner of the hall with a delightful exhibit of perennial asters and early chrysanthemums; the arrangement was very fine, and the groupings of Le Pactole, Champagne, Savoiê, Normandie, Perle Chatillonaise, and Belle Mauve chrysanthemums were delightful. Phloxes, delphiniums, and kniphofias were also displayed.

Miss V. Jeffrey, Rozel, Gymal Road, Lee, brought up some splendidly-executed water-colour drawings of different flowers, so arranged as to be excellent botanical studies; the minuteness of detail was remarkable.

ORCHID COMMITTEE.

Acineta chrysantha, the handsome Cattleya Fabia, the bold Cypripedium Franconia, Spathoglottis Fortunei, and the very curious Bulbophyllum Medusæ were conspicuous in the group of orchids from Messrs. Sander and Sons, St. Albans.

A bright exhibit from Messrs. Armstrong and Brown, Tunbridge Wells, was notable for its numerous examples of Cattleya Fabia, C. Armstrongi—very freely flowered, C. Iris, Cypripedium Thalia var. Mrs. F. Wellesley, C. Germaine Opoix Westfield var., Brassocattleya Leemanæ, Dendrobium, Cœlogyne, etc.

Messrs. Hassall and Co., Southgate, made up a bold group of Cattleya labiata varieties, some of the light forms being very charming.

Messrs. Charlesworth and Co., Haywards Heath, put up a small group of orchids that contained fine forms of Cattleya labiata, C. Wendlandiana, C. Golden Oriole, the finely marked Odontoglossum Aireworth, and Miltonia Bleuiana nobilior.

A bright orchid group from Messrs. S. Low and Co., Bush Hill Park, Enfield, was rendered particularly effective by reason of its arching spikes of Oncidium varicosum, O. oblongatum, and O. oblongatum citrinum; dendrobium, phalænopsis, and numerous lælio-cattleyas added their meed of rich colours.

Messrs. J. Cypher and Sons, Cheltenham, contributed a bright group of cypripediums, Vanda cærulea, and lælio-cattleyas; Bulbophyllum grandiflorum, Cattleya Mrs. J. W. Whiteley, and Cypripedium Niobe were notable subjects.

Mr. Alexander, orchid grower to Lieut.-Colonel Sir G. Holford, Westonbirt, brought up Lælio-cattleya luminosa aurea with pale yellow sepals and petals and rich purple lip (F.C.C.). MM. Maron and Sons, Brunoy, France, submitted Cattleya Fabia var. Vigeriana with nine grand flowers; Brasso-cattleya Maronæ, and B.-c. Rhadames, with a rosy-edged lip.

Mr. Hopkins, gardener to F. Wellesley, Esq., showed a fine form of Brasso-lælia Veitchi, Cattleya labiata Lady Leese, and L.-c. Mrs. Phayre.

Mr. E. V. Low, Vale Bridge, Haywards Heath, presented Brasso-cattleya Queen Alexandra Vale Bridge var., with two splendid flowers; and a large specimen of Cattleya labiata, carrying forty-six blooms.

Messrs. Mansell and Hatcher, Rawdon, Leeds, gained an A.M. for the white Vanda Kimballiana alba. Mr. Barker, gardener to W. [illegible], Esq., Hessle, showed Cypri-

Miss V. Jeffrey, Rozel, Gymal Road, Lee, brought up some splendidly-executed water-colour drawings of different flowers, so arranged as to be excellent botanical studies; the minuteness of detail was remarkable.

ORCHID COMMITTEE.

Acineta chrysantha, the handsome Cattleya Fabia, the bold Cypripedium Franconia, Spathoglottis Fortunei, and the very curious Bulbophyllum Medusæ were conspicuous in the group of orchids from Messrs. Sander and Sons, St. Albans.

A bright exhibit from Messrs. Armstrong and Brown, Tunbridge Wells, was notable for its numerous examples of Cattleya Fabia, C. Armstrongi—very freely flowered, C. Iris, Cypripedium Thalia var. Mrs. F. Wellesley, C. Germaine Opoix Westfield var., Brassocattleya Leemanæ, Dendrobium, Cœlogyne, etc.

Messrs. Hassall and Co., Southgate, made up a bold group of Cattleya labiata varieties, some of the light forms being very charming.

Messrs. Charlesworth and Co., Haywards Heath, put up a small group of orchids that contained fine forms of Cattleya labiata, C. Wendlandiana, C. Golden Oriole, the finely marked Odontoglossum Aireworth, and Miltonia Bleuiana nobilior.

A bright orchid group from Messrs. S. Low and Co., Bush Hill Park, Enfield, was rendered particularly effective by reason of its arching spikes of Oncidium varicosum, O. oblongatum, and O. oblongatum citrinum; dendrobium, phalænopsis, and numerous lælio-cattleyas added their meed of rich colours.

Messrs. J. Cypher and Sons, Cheltenham, contributed a bright group of cypripediums, Vanda cærulea, and lælio-cattleyas; Bulbophyllum grandiflorum, Cattleya Mrs. J. W. Whiteley, and Cypripedium Niobe were notable subjects.

Mr. Alexander, orchid grower to Lieut.-Colonel Sir G. Holford, Westonbirt, brought up Lælio-cattleya luminosa aurea with pale yellow sepals and petals and rich purple lip (F.C.C.), MM. Maron and Sons, Brunoy, France, submitted Cattleya Fabia var. Vigeriana with nine grand flowers; Brasso-cattleya Maronæ, and B.-c. Rhadames, with a rosy-edged lip.

Mr. Hopkins, gardener to F. Wellesley, Esq., showed a fine form of Brasso-lælia Veitchi, Cattleya labiata Lady Leese, and L.-c. Mrs. Phayne.

Mr. E. V. Low, Vale Bridge, Haywards Heath, presented Brasso-cattleya Queen Alexandra Vale Bridge var., with two splendid flowers, and a large specimen of Cattleya labiata, carrying forty-six blooms.

Messrs. Mansell and Hatcher, Rawdon, Leeds, gained an A.M. for the white Vanda Kimballiana alba. Mr. Barker, gardener to W. Burkinshaw, Esq., Hessle, showed Cypripedium Lord Ossulston with nine blooms, each with a very big white dorsal sepal.

Vanda cærulea, Cattleya gigas, and C. aurea were conspicuous in the small group of orchids staged by Messrs. J. and A. McBean, Cooksbridge. Particularly fine was Lælio-cattleya St. Gothard McBean's var. (F.C.C.), with a splendid violet-purple lip and golden throat. Odontioda Charlesworthi and Cypripedium insigne Harefield Hall were other good subjects included.

FRUIT AND VEGETABLE COMMITTEE.

A dish each of forty-seven stocks of carrots, from the R.H.S. gardens at Wisley, proved very interesting. Most of the varieties were red, but there were two white-rooted sorts. The intermediate forms were well represented, and so were the short-horn and the Model sections; but those that appeared to create most interest were the cylindrical varieties of the Nantes and Paris Market types.

Messrs. Ambrose Palmer and Co., Grosvenor Street, W., showed good dishes of popular kinds of apples and pears.

About 70 dishes and baskets of potatoes from Mr. W. E. Sands, Hillsborough, Ireland, represented almost as many varieties, and included a number of seedlings; The Colleen, Irish Queen, Irish Hero, President, Factor, Rent-Payer, Sharpe's Victor, King George V., and the old Skerries were varieties prominently good.

Mr. McDonnell, Shepherd's Bush, showed some bunches of Black Hamburgh grapes ripened out of doors.

CERTIFICATES AND AWARDS.

First-class Certificate.—To Lælio-cattleya Luminosa aurea, from Lieut.-Colonel Sir G. Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester; to Lælio-cattleya St. Gothard, McBean's var., from Messrs. J. and A. McBean, Cooksbridge.

Award of Merit.—To Vanda Kimballiana alba, from Messrs. Mansell and Hatcher, Rawdon, Leeds; to Nerines Mrs. F. R. Balfour, Snowflake, Mrs. Meade Waldo, and Hon. Miss Gibbs, from H. J. Elwes, Esq., F.R.S. (gardener, Mr. Walters); to Clerodendron Fargesi, from the Director, Royal Gardens, Kew; to Asters Profusion and Amethyst, from Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree; to Chrysanthemums Dorothy Dann and Bronze Goacher, from Messrs. W. Wells and Co., Merstham; to Berberis verruculosa and Lonicera nitida, from Messrs. Jas. Veitch and Sons, Chelsea; to decorative dahlia Delice, from Messrs. Carter Page and Co., London Wall; and to plum Coe's Violet, from Mr. J. Vert, gardener to Lord Howard de Walden, Saffron Walden.

MEDALS.

Silver-gilt Flora.—To Messrs. H. B. May and Sons, Edmonton, for ferns and begonias; to Messrs. Jas. Veitch and Sons, Chelsea, for trees and shrubs and greenhouse plants; to Mr. L. R. Russell, Richmond, for bamboos and berried shrubs.

Silver-gilt Banksian.—To Messrs. W. Cutbush and Son, Highgate, for climbers, asters, and carnations.

Silver Flora.—To Messrs. Bakers, Wolverhampton, for dahlias; to Mr. J. Box, Lindfield, for hardy autumn flowers; to Messrs. J. Cheal and Sons, Crawley, for autumn foliage; to Mr. H. J. Elwes, F.R.S., Colesbourne, for nerines; to Messrs. Thos. S. Ware, Lim., Feltham, for dahlias and chrysanthemums; to Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. S. Low and Co., Enfield, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. Hassall and Co., Southgate, for orchids; and to Miss Jeffery, for botanical studies.

Silver Banksian.—To Messrs. J. and A. McBean, Cooksbridge, for orchids; to Messrs. Carter Page and Co., London Wall, for dahlias; to Messrs. W. Wells and Co., Merstham, for chrysanthemums; to Messrs. Ambrose and Co., Grosvenor Street, W., for fruits.

Silver Knightian.—To Mr. W. E. Sands, Hillsborough, Ireland, for potatoes.

Bronze Flora.—To Messrs. Paul and Son, Cheshunt, for rose hips and autumn foliage.

Bronze Banksian.—To Messrs. C. Maron and Sons, Brunoy, for orchids.

Bronze Knightian.—To Mr. W. B. McDonnell, Shepherd's Bush, for Black Hamburgh grapes; Messrs. Allwood Bros., for carnations.

SCIENTIFIC COMMITTEE, OCTOBER 10.

Present: Mr. J. T. Bennett Poë, M.A. (in the chair); Messrs. E. M. Holmes, F.L.S., A. Worsley, W. Hales, W. C. Worsdell, J. O'Brien and F. J. Chittenden (hon. sec.).

VARIATION IN ELM.—Mr. W. C. Worsdell drew attention to the variation which had occurred this year, both at Kew and Cambridge, in the foliage of Ulmus glabra, Miller. At the base of many leaf-blades, from one to three extra small leaflets had developed on the petiole. These, when on the side of the leaf in which the blade is usually less well developed, appeared to be complementary growths, but in several of the leaves the blade was symmetrical. A second variation, of considerable frequency, was seen in the forking of the midribs of the leaves, sometimes to the base, so as to produce apparently two leaves at a node, sometimes less deeply. In some few cases also some of the leaves formed ascidia.

RUDBECKIA TRILOBA MALFORMED.—Mr. Wordsell also showed an inflorescence of Rudbeckia triloba, with foliage leaves developing from the apex, through the centre of the capitulum.

MENTHOL PLANT.—Mr. Holmes showed a specimen of the true Menthol plant from his garden. The plant was derived from one growing in Berlin. It is a form of Mentha arvensis called piperascens, and is a native of Japan.

FASCIATION IN CHRYSANTHEMUM MAXIMUM.—Mr. J. R. Jackson sent an example of a fasciated stem and inflorescence in this plant from Lympstone. This species appears to be very subject to fasciation.

ONION BULB WITH LATERAL GROWTHS. — Mr. E. E. Turner sent from Coggeshall, Essex, an onion bulb having numerous greenish bulbils growing from around the base, so that the original bulb was surrounded at its base by numerous out-growths. It may possibly have arisen from a second growth being developed after a check imposed by drought.

CABBAGE WITH HAIRY LEAVES.—Mr. A. Simmonds sent from Mitcham, Surrey, a cabbage leaf having hairs upon both surfaces, especially upon the veins. The wild form is often hairy, but hairiness appears to be very rare in the cultivated varieties.

ROTTING OF NARCISSUS BULBS.—Rev. J. Jacob sent some narcissus bulbs which had been attacked by the fungus Fusarium bulbigenum. This was first described in "Grevillea," Vol. XVI., p. 49, but appears not to have been troublesome since.

APPLES DISEASED.—Mr. Rogers sent from Hexworthy some apples with peculiar greenish depression on the surface, showing a well-marked brown marginal line, which also limited the spots on the inner side, being there about ¼in. below the surface. The trouble had, apparently, developed in the store, and had occurred in a large number of varieties. Mr. Chittenden took them for further examination.

VOTE OF CONDOLENCE.—A vote of condolence was sent Mr. E. A. Bowles, on the death of his mother.

PACKING FRUIT, ETC.—The proper mode of packing fruit and vegetables for market is fully described and illustrated in the Gold Medal Essay of the Worshipful Company of Fruiterers, entitled Packing and Selling Fruit and Vegetables. Price 1s. from booksellers, or 1s. 3d. by post from Gardeners' Magazine Office, 148, Aldersgate Street, London.

Royal Horticultural Society of Ireland.

The winter fruit show of the Royal Horticultural Society of Ireland, assisted by the Department of Agriculture, was held in the buildings of the Royal Dublin Society, Ballsbridge, on the 18th and 19th inst. The weather on the first day was particularly favourable, and in the afternoon the attendance fairly good. A show so well organised, at so much expense, and made so attractive in every way, and with the view of encouraging an important industry for the country—that of fruit growing—should have attracted a larger number of the fashionable and wealthy class. In every other respect the show seemed a completely successful venture, being a record one in the entries in the numerous classes, and, on the whole, the quality and size of most of the fruit on exhibition have heretofore scarcely been equalled. The colours, in dessert apples—those from the Southern district especially—were perfection. In some of these classes the entries were large, Cox's Orange Pippin leading the number with 73 dishes. In Ireland this favourite dessert variety still easily leads in popularity. Mr. R. Dalton, of Pilltown, Kilkenny, took first with medium-sized, brilliantly coloured fruit; the second going to Mr. N. Coghlan, and the third to W. Coffey, Esq., of Newmarket-on-Fergus, in very close competition. The class for Allington Pippin was also a large one, and the first prize was awarded to Mr. Coghlan, also of Pilltown, with medium fruits of wonderful colour; the second prize going to Mr. R. Dalton, Pilltown. King of the Pippins was another good class, with Mr. Whiting, of Hereford, occupying the premier position with a really superb dish in size and colour, and Lady Fitzgerald second. For Ribston Pippin the first went to Mr. Steward for very big fruit, and second to Mr. Hannon.

The first prize for Worcester Pearmains was awarded to Mr. Dalton, of Pilltown, who had a very highly-coloured dish, and second to Mr. Wm. Coffey, Newmarket-on-Fergus. Mr. Bowers, of Silversprings, Kilkenny, gained first for Rival, as well as first for a collection of twelve dishes of cooking apples, with Mr. Coffey, of Newmarket-on-Fergus, second. Good fruits of Charles Ross were shown by Mr. R. J. Brown, who was successful by winning first prize. The premier award for James Grieve went to Mr. J. Cooney, Kells, but this early apple was rather past its best, and there were only seventeen dishes. Mr. J. Cooney also secured first in a collection of six dishes of cooking apples. For an excellent collection of six dishes of dessert apples Mr. J. B. Jameson, of Bray, gained the premier award, very handsome dishes of Rival and Allington being conspicuous. The chief award for a decorated table of eighteen dishes of apples went to Mr. J. Jameson, of Portmarnock. In the class for a collection of twelve dishes of eight cooking and four dessert apples, open to amateurs only who employ a gardener, premier honours were obtained by Lady Fitzgerald, who showed extra fine Cox's Pomona, Bramley's Seedling, and Warner's King; the second prize was awarded to Mr. J. Jameson, of Portmarnock. Some other first prize winners in other classes of dessert apples were Mr. G. Butler, for a well-finished dish of King of Tomkin's County, in a miscellaneous class of ripe fruit, not elsewhere classed.

In a competition of forty-eight dishes of late kinds not classed, Mr. S. Bowles won first with handsome high-coloured fruit of Barnack Beauty. For American Mother Mrs. Bowers won first prize. For russets Lady Annaly, and for Blenheim Orange Mr. C. S. Roynane obtained premier awards. Among the single dish classes for culinary apples Bramley's Seedling, comprising over seventy dishes, made an imposing display. Lord Derby, Blenheim Pippin, Lane's Prince Albert, Bismarck, Gascoyne's Scarlet, Newtown Wonder, Warner's King, Peasgood's, and The Queen formed other extensive classes. Lane's Prince Albert was mostly of very high colour, and Bramley's Seedling so in most cases, and Newton Wonder particularly rich in colour. The first prize winners in some of the many classes were, for Bramley, Lady Annaly, with perfectly uniform, full-sized fruit; for Blenheim Orange, Mr. K. F. Malcomson; for Bismarck, Mr. Wm. Coffey; for Gascoyne's Scarlet, Mr. Wm. Nulty, in very close competition with the second prize winner, who was Mr. J. O'Donnell. For Beauty of Kent, the Earl of Drogheda gained first; for Lord Derby, which was a very fine class, Mr. J. Kennedy was awarded first for a magnificent dish; for Lane's Prince Albert, another grand class, Mr. A. G. Bowers obtained first prize with a superb dish, both colour and form being ideal. Other firsts were for Newton Wonder, Mr. A. Claud Ellis; for Peasgood's, Mr. J. Nulty; and for The Queen, Mr. M. Kennedy, who was easily first with grand fruit. The Earl of Drogheda gained first prize in a class for any other early cooking kind not classed with fine fruit of Loddington Seedling. In this class appeared fine examples of Queen Caroline, of brightest yellow; Bess Pool, dark red; Waltham Abbey Seedling, very large. For any other variety, late cooking, not classed in a big competition, Mrs. Kennedy gained first for King Edward of fine form and size. Other markedly good kinds in competition in this class were Beauty of Stoke, Cobham, American Greening, and Emperor Alexander. In the class for Royal Jubilee, the dishes were uniformly good, for which Mr. James Kennedy was awarded first prize.

Pears were also well shown. For the collection of six dishes of dessert varieties, Lady Clara Fitzgerald, Newmarket-on-Fergus, was awarded first, and Mr. B. H. Barton, of Straffan House, second. For the collection of four dishes of dessert pears the first was won by Mr. J. R. Jameson, of Bray. Lady Kenure Park gained first for a dish of Doyenne du Comice. For Pitmaston Duchess Mr. Mapother, of Roscommon, was first. Some other winners in the various other single dish classes for pears were Lady Redmond, Earl of Drogheda, Alderman Bewley, Rathgar; and Mr. E. D'Olier, Knocklin.

The show of grapes was not a remarkable one, but the competitions for apple packing were keen. Vegetables were very well shown. In the collections the closeness of the competitions, the general good quality, and the neatness of the staging, made a most attractive display. The first prize for twelve kinds of vegetables went to Mrs. S. J. Brown, Naas. For six kinds, the first prize was won by Alderman Bewley, who was also awarded first for six very well-grown specimens of Salvia splendens.

The chrysanthemums were not so prominent a feature as in some years past, but the quality of the blooms shown was very good. The prize for the stand of twenty-four Japanese blooms was won by Mr. J. Jameson, Portmarnock, who also won first in several other classes, some of the most conspicuous of the blooms were Elsa Fulton, White Queen, Mrs. N Davis, Yellow Skanklin, and F. Joliffe. For the stand of twelve blooms the first prize was awarded to the Hon. C. F. Crichton, Mullaboden; second to Mr. W. Robertson, of Hermitage. The competition was close between the first and second prize winners. Noticeable winning blooms were Mrs. A. T. Millar, Mrs. W. Knox, and F. Joliffe. Mr. Robertson showed Formality and F. Penford. For a stand of six blooms Mr. Westby, Roebuck Castle, was first. The competition for six vases of carnations was won by Alderman Bewley, some markedly good varieties being Mrs. Burnett, White Lady Bountiful, very lovely; Britannia, and Mrs. T. W. Lawson. The nurserymen and traders' stands were numerous and elaborate, and added considerably to the general interest of the show. Messrs. Bakers, of Wolverhampton, were awarded a gold medal for a very showy and attractive display of named hybrid pæony-flowered dahlias. Sir James Mackey, of Sackville Street, was also awarded a gold medal for the best stand containing fruit, flowers, and vegetables. This stand was extensive and of varied order. In this were shown hybrid gerberas of vivid colours, which were very beautiful and attractive. Messrs. C. Ramsay, of Ballsbridge, were awarded a gold medal for the finest group of foliage and flowering plants. Messrs. Watson, of Clontarf, were awarded a gold medal for a fine stand of hardy fruits. Many other firms gained awards, and added interest to a very fine exhibition.

In connection with the fruit show, on the second day in the Industrial Hall the Fruit Conference was held. The attendance was large and representative, and comprised fruit growers from all parts of Ireland. Mr. T. W. Russell, M.P., Vice-President of the Department of Agriculture, presided.

Royal Scottish Arboricultural Society.

A meeting of the Aberdeen branch of this society was held in Aberdeen University Buildings on Saturday afternoon, 14th inst. There was a capital attendance of leading landed proprietors, foresters, nurserymen, etc., from the North-east of Scotland. Mr. Sydney J. Gammell, of Drumtochty and Countesswells, president of the branch, occupied the chair. After some preliminary business had been transacted, the Chairman called upon Mr. J. A. Duthie, Pinewood Park Nurseries, Aberdeen, to read his paper upon "The Trade Nursery and its Function in the Extension of Afforestation." Mr. Duthie said he wished to discuss whether our knowledge, our skill, our experience of plant culture would be required when afforestation came. He did not mean to go into a history of the nursery trade, but would lay stress on points of interest upon which no doubt there might be very much difference of opinion. There were few trade nurseries prior to 1750. No doubt the huge plantations made by the Duke of Atholl and other proprietors in the latter part of the 18th century created a demand for forest trees over and above what could be raised in their estate nurseries. There were still a few firms in Scotland who were established in the latter end of the 18th century, although not a few old firms succumbed during the '80's, when agricultural depression became so acute, and put a stop to estate planting operations generally. At the present moment he was doubtful if there was more than half the acreage under nursery crops that existed, say, between 1850 and 1870, when rents and prices of agricultural produce reached high-water mark. The last quarter of the 19th century were barren years for the nursery trade, a poor and irregular demand, and a steady increase in taxes and working expenses making the business far from profitable.

Mr. Duthie then proceeded to speak on the situation, soil, etc., of the nursery. Briefly, the situation should, if possible, be a natural well-drained soil with a gentle slope, not subject to late spring or early autumn frosts, possessing a kindly soil, more or less sheltered in spring and early summer from prevailing cutting winds, and last, but not least, land as far as possible free from weeds and stones. The lecturer then proceeded to deal with the most suitable manures and recommended bone-meal as the safest artificial. Proceeding to deal with the seeds used, he emphasised the point that the selection of good seeds from healthy sources was of the greatest importance. Instead of criticising nuserymen for growing seeds which were, in some cases, faulty, why should not landowners co-operate with them, and prevent the collection of seeds from badly grown or diseased trees? Nurserymen could not do so, and were powerless in the matter. Seeing the question was one of national importance, could not landowners take the business of seed collecting into their own hands? No one would welcome a solution of this matter more than bona fide nurserymen. He was perfectly satisfied that every Scottish nurseryman who valued his reputation, present and prospective, was anxious to secure the best possible seeds, irrespective of price. He could never quite understand why all the vices in creation should be attributed to home-grown larch, and all the virtues to Tyrolese. Had they any surety that the foreign article fulfilled all the conditions of what good seed should be? Perhaps it might be a case of "Where ignorance is bliss, 'tis folly to be wise." As to the respective merits of home and foreign larch, he did not wish to express an opinion, but there was no doubt that up to two or three years of age plants raised from home seed were much superior in growth and hardiness to those raised from foreign seed. As long as there was sufficient supply of native Scots fir available, he saw no necessity for introducing an inferior type to our woods. Manifestly, the whole business of seed collecting was not altogether in a satisfactory condition. The same difficulties had to be met with in the home nursery, but with this difference, that the prorpietor's whole capital was not at stake, nor was he confronted with one of the greatest initial difficulties—the irregular and intermittent demand. They sowed in faith and sometimes reaped—a bonfire.

There need not be any antagonism between trade and private nurseries, for both were, he believed, indispensable. Let the requirements be indicated, assure the nurseryman of a regular and constant demand, throw open for the collection of native seeds the best woods in the country—or, better still, failing Government centres, let landed proprietors take the business of seed collecting into their own hands, and supply the nurseryman with the genuine article.

When the Forestry Commissioners' report came out some years ago recommending that in Scotland something like nine million acres were suitable for afforestation, the first question that confronted practical foresters was where the requisite number of plants were to be procured if afforestation of such large areas should take place. That need not be a drawbock. Create the demand, and the nurserymen would provide the supply—a supply that in quantity, quality, and price would render it unnecessary to cross the German Ocean. The most regrettable feature in foreign competition was, he thought, the importation of foreign Scots fir. He had already mentioned that it was so liable to attack by leaf-shedding fungus as to make it scarcely worth growing. If home larch was inferior to Tyrolese, why plant Continental Scots fir, which everyone admitted was inferior to our native pine? What would the timber merchant's verdict be in the matter when the wood, if ever it came to a marketable size, reached maturity? To his mind there were three serious objections to the introduction of the foreign produce into this country—first, its liability to leaf-shedding fungus, which might become epidemic and be injurious to Scots pine plantations as larch canker was to larch; second, the timber produced would in all likelihood be inferior in every way to our finest indigenous pine; and, third, seed might be collected in the future from the foreign form, which might lead to the deterioration of the type. In fact, he would go so far as to advocate the prohibition of the importation of Continental Scots pine.

Several speakers having most favourably criticised the paper, including Mr. William Dawson, lecturer in forestry at Aberdeen University, and Mr. J. D. Crozier, forester on the Durris estates, near Aberdeen, a very hearty vote of thanks was accorded Mr. Duthie, on the motion of the chairman, for his very valuable and interesting contribution.

The usual votes of thanks terminated the meeting.

National Chrysanthemum Society.

The Floral Committee met at Essex Hall, Strand, in the afternoon of October 23, and had a goodly number of blooms to consider, these being sent by Messrs. W. Wells and Co., Mr. Jinks, Mr. Salsbury, Mr. H. J. Jones, Mr. Perry, Messrs. Cragg, Harrison, and Cragg, etc. Six First-class Certificates and six Commendations were granted; and the descriptions of the flowers so honoured will be found under "New Plants."

Votes of thanks were passed to Messrs. Low and Shawyer, of Uxbridge, and Messrs. Cragg, Harrison, and Cragg, of Heston, for their courtesy and hospitality on the occasion of the visits of the committee to their establishments, and such thanks were recorded on the minutes.

The committee regarded Golden Glory as identical with Cranford Yellow, already certificated by the N.C.S.; under these names Messrs. W. Wells and Co. submitted numerous blooms, and no one could distinguish any difference between the flowers.

At the general committee meeting held at Carr's Restaurant, there was a large attendance. The death of Mr. Reeve, of Barnet, a former cultivator of specimen chrysanthemums, was reported, and a silent vote of condolence passed to his relatives. A financial balance of £43 11s. 8d. was reported to date. Whether the use of electric lights in a table decoration was permissible was discussed at some length, but it was pointed out that the class specification did not prohibit the use of lights, and as lights were commonly used in table decorations they could not disqualify.

The Publications Sub-Committee reported the desirability of obtaining a descriptive account of the November show for publication in the schedule, as such accounts, if carried out annually, would be of great historic interest and value, as showing the development of certain classes of flowers and the decline of others. The recommendation was agreed to, and a sum not exceeding three guineas was granted for the preparation of such account.

The Chairman reported what had taken place at the Mansion House meeting that afternoon respecting the Crystal Palace and its purchase for the nation. As the Official Receiver has power to act up to October 31, 1912, it was agreed to proceed as far as possible in connection with dates for shows in that year.

Six new Fellows and sixteen new ordinary members were elected.

Some humour was imported into the proceedings by the very emphatic desire on the part of some members that the society's dinner on November 29 should be "a real English one."

Dundee Horticultural Association.

The first meeting of the session was held in the Technical College on the 19th inst., when the hon. president, W. S. Melville, Esq., presided. Mr. J. B. Corr gave an admirable and interesting lecture on "Some Curious Habits and Habitats of Plants." After contrasting tropical forests with the alpine flora, and pointing out the natural adaptation to environment in extreme cases, the lecturer held his audience spellbound while he talked of the humble flowers of the field and hedgerows, marsh plants, aquatics, climbers, lichens, mosses, ferns, and fungi, all of which he discussed admirably, and pointed out many of their peculiarities. His examples of pollination and perpetuation of species were exceedingly well chosen, and proved of much interest, while the extent of his information showed him to be an ardent student of nature, and one capable of imparting his information to others. A large Up-to-date potato weighing 2¾lb., exhibited by Mr. J. S. Ritchie, Monifieth, created much interest.

Broughty Ferry Horticultural Society.

At the ordinary monthly meeting on the 17th inst., Mr. Wm. MacDonald, head gardener at Mount Melville, was the lecturer, taking as his subject "Points for Gardeners, Young and Old." In weighty words the lecturer denounced the average young gardener for his lack of interest in his daily occupation. He was either given to sport, or of indolent, careless, and disrespectful habits, and fast losing his caste. This was accountable from the fact that young apprentices were drawn from a poor source, encouraged by the "keeping wage" advanced in no other trade. He deplored the fact that the best young men were emigrating where better remuneration was obtained, and he thought that something ought to be done to keep the best talent at home, and keep wastrels out of the gardening ranks; he suggested lower wages and longer services for apprentices, a higher standard of education, and some combined effort to hall mark the best, so that worth would be recognised.

In an animated discussion which took place the President, Messrs. Grant, Slater, Meston, Masson, Bell, Stewart, Christeson, and others took part, after which the lecturer was cordially thanked.

In a competition for three leeks, three heads of celery, and three onions, Mr. John Campbell, Forbes Court Gardens, was first, and Mr. James Bethel, The Grange Gardens, second.

Reading Gardeners' Association.

At the fortnightly meeting, held in the Abbey Hall (by kind permission of Messrs. Sutton and Sons), on Monday, there was again a very large attendance, the President (Mr. F. B. Parfitt) occupying the chair.

The speaker for the evening was one of the initiators of the association, Mr. G. Hinton, gardener to T. Allsopp, Esq., Downham Lodge, Caversham, and his subject was "Vegetables—Preparing for Winter." Mr. Hinton, who has been long known to his confrères as a clever vegetable grower, opened his lecture by stating that his remarks would be more particularly addressed to those who held what were known as single-handed places, and who had to think and act for themselves. An exceedingly interesting paper followed, Mr. Hinton giving practical information which had been culled from his long experience in the gardening world, instancing for example the method he had used in raising an abundance of cabbage plants during the past autumn, while many of his friends had altogether failed in the trying season.

A particularly animated and instructive debate followed, which was maintained to the close of the meeting, when a hearty vote of thanks to Mr. Hinton was carried with acclamation.

A certificate of cultural merit was awarded to Mr. G. Tovey, The Gardens, Leighton Park, for a group of zonal pelargoniums; and Mr. A. Abraham, gardener to Mrs. Bird, Shrublands, Earley, Reading, was highly commended for a collection of apples and pears. Mr. A. Giles, gardener to H. Dunlop, Esq., exhibited a bouquet of dahlias; and Mr. Shipley, head gardener to F. W. Nicholson, Esq., sent some wonderfully robust growth, seven feet in height, of Love-Lies-Bleeding.

Bournemouth Gardeners' Association.

On Tuesdays, October 17, a concert in aid of the Royal Gardeners' Orphan Fund was given in the Avenue Assembly Room, and proved a great success. Alderman J. Eames Beale, J.P., presided, supported by J. H. Ralph Smythe, Esq., J.P., the president of the association. Both the ladies and gentlemen who rendered the programme acquitted themselves very creditably indeed. During the interval Mr. Beale made a very eloquent appeal to the company—a large one—to swell the funds and so assist those who are in less favourable circumstances. He spoke of the great good such societies did, of the relief given to widows left lonely, and stated that he once conversed with a celebrated Japanese visitor to this country, and, during their conversation he asked the gentleman what struck him most in this country, and suggested that possibly it would be the Navy. "No," said the gentleman, "your magnificent hospitals, orphanages, and similar institutions impress me most, and the grand work carried on in connection with them."

Charges were not made for admission to the concert, but a collection was made, which on this occasion amounted to £4 7s. 5d., and was later made up to £4 14s.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

PALLID CUCUMBER LEAVES.—A., Carisbrooke: The leaf sent us carried a goodly number of red spiders, quite sufficient to account for the trouble. Some amount of dryness at the roots as well as in the atmosphere is the cause of the attack, as evidenced by the thin foliage. Spray or sponge the leaves with a solution of flowers of sulphur, and follow this up with frequent syringings as weather permits, taking care to wet both surfaces of each leaf as well as the immediate surroundings. Pay careful attention to watering, as cucumbers should on no account be allowed to get dry at the roots. Give small top-dressings of equal parts of loam and cow manure as soon as roots appear through the surface soil.

TUBEROUS BEGONIAS.—F. E., Derby: Lay the pots on their sides on the greenhouse staging for a few days, allowing the soil and stems to face the sun. Here the old stems will soon ripen and detach themselves from the tuber, and as this happens, remove the pots to a less conspicuous place where the soil and tubers will be kept dry and in a temperature of about 50 degrees. If the pots are needed, shake the tubers free from soil, and place them in little bags or baskets, with labels attached, in the seed cupboard or similar dry frost-proof place.

RUBBER SEEDS.—W. B. S., Southampton: The seeds are those of the Para Rubber tree, Hevea braziliensis, but quite half of those sent us were dead, although they appeared to be sound.

GLAZING HONEY SECTIONS.—F. E. J., Epping: For glazing sections, glass cut to the correct size may be purchased of any dealer in bee appliances, together with the strips of paper lace edging, which, when pasted round the angle formed by the glass and wood, serve to fix the glass on. The local glazier will gladly cut up waste glass to the small size (viz., 4 3-16in. by 4 3-16in.) required, while neatly printed bands of coloured paper, 19in. by 3in., can be used instead of the lace edging. These bands cost about 7s. per 1,000. They are more easily pasted on than the paper lace edging, and make much firmer and neater work, while they also give an opportunity of placing the names of the apiary and retailer on each section. Neat cardboard cases, plain

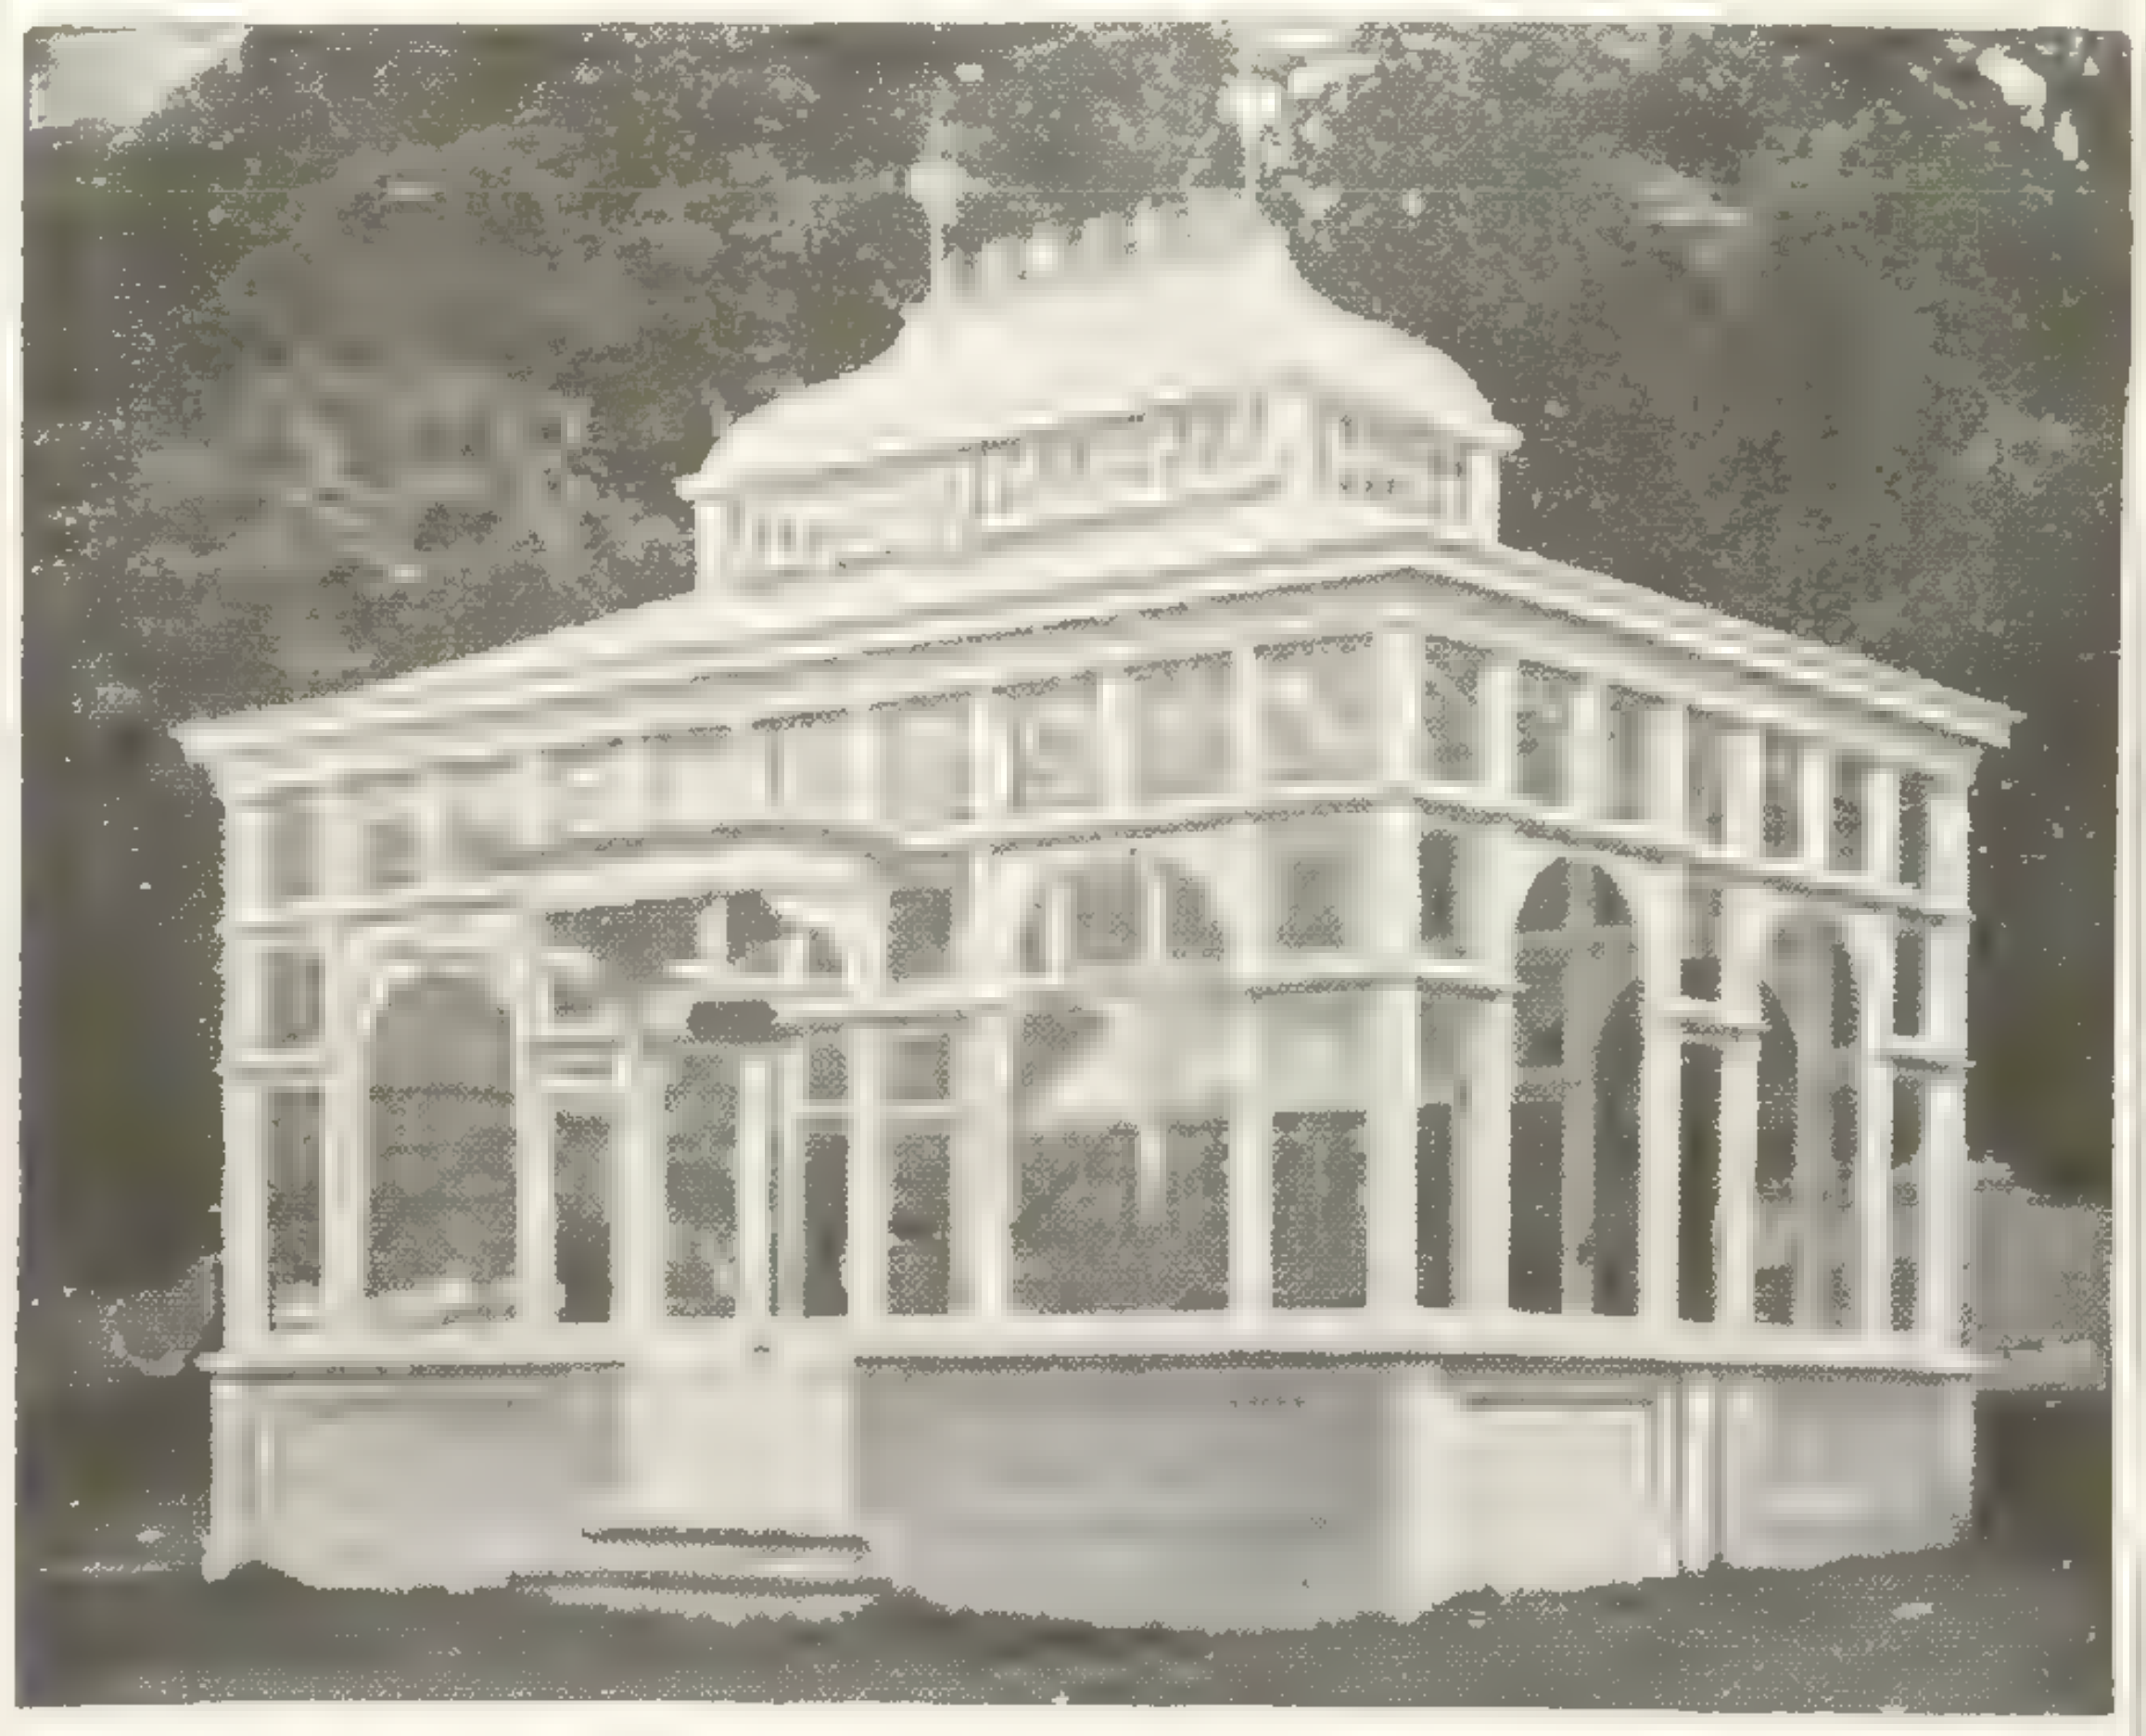
The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price 10/6. Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).

BOULTON & PAUL, LTD., HORTICULTURAL BUILDERS, Norwich.

ATTRACTIVE, PRACTICAL GLASSHOUSES.

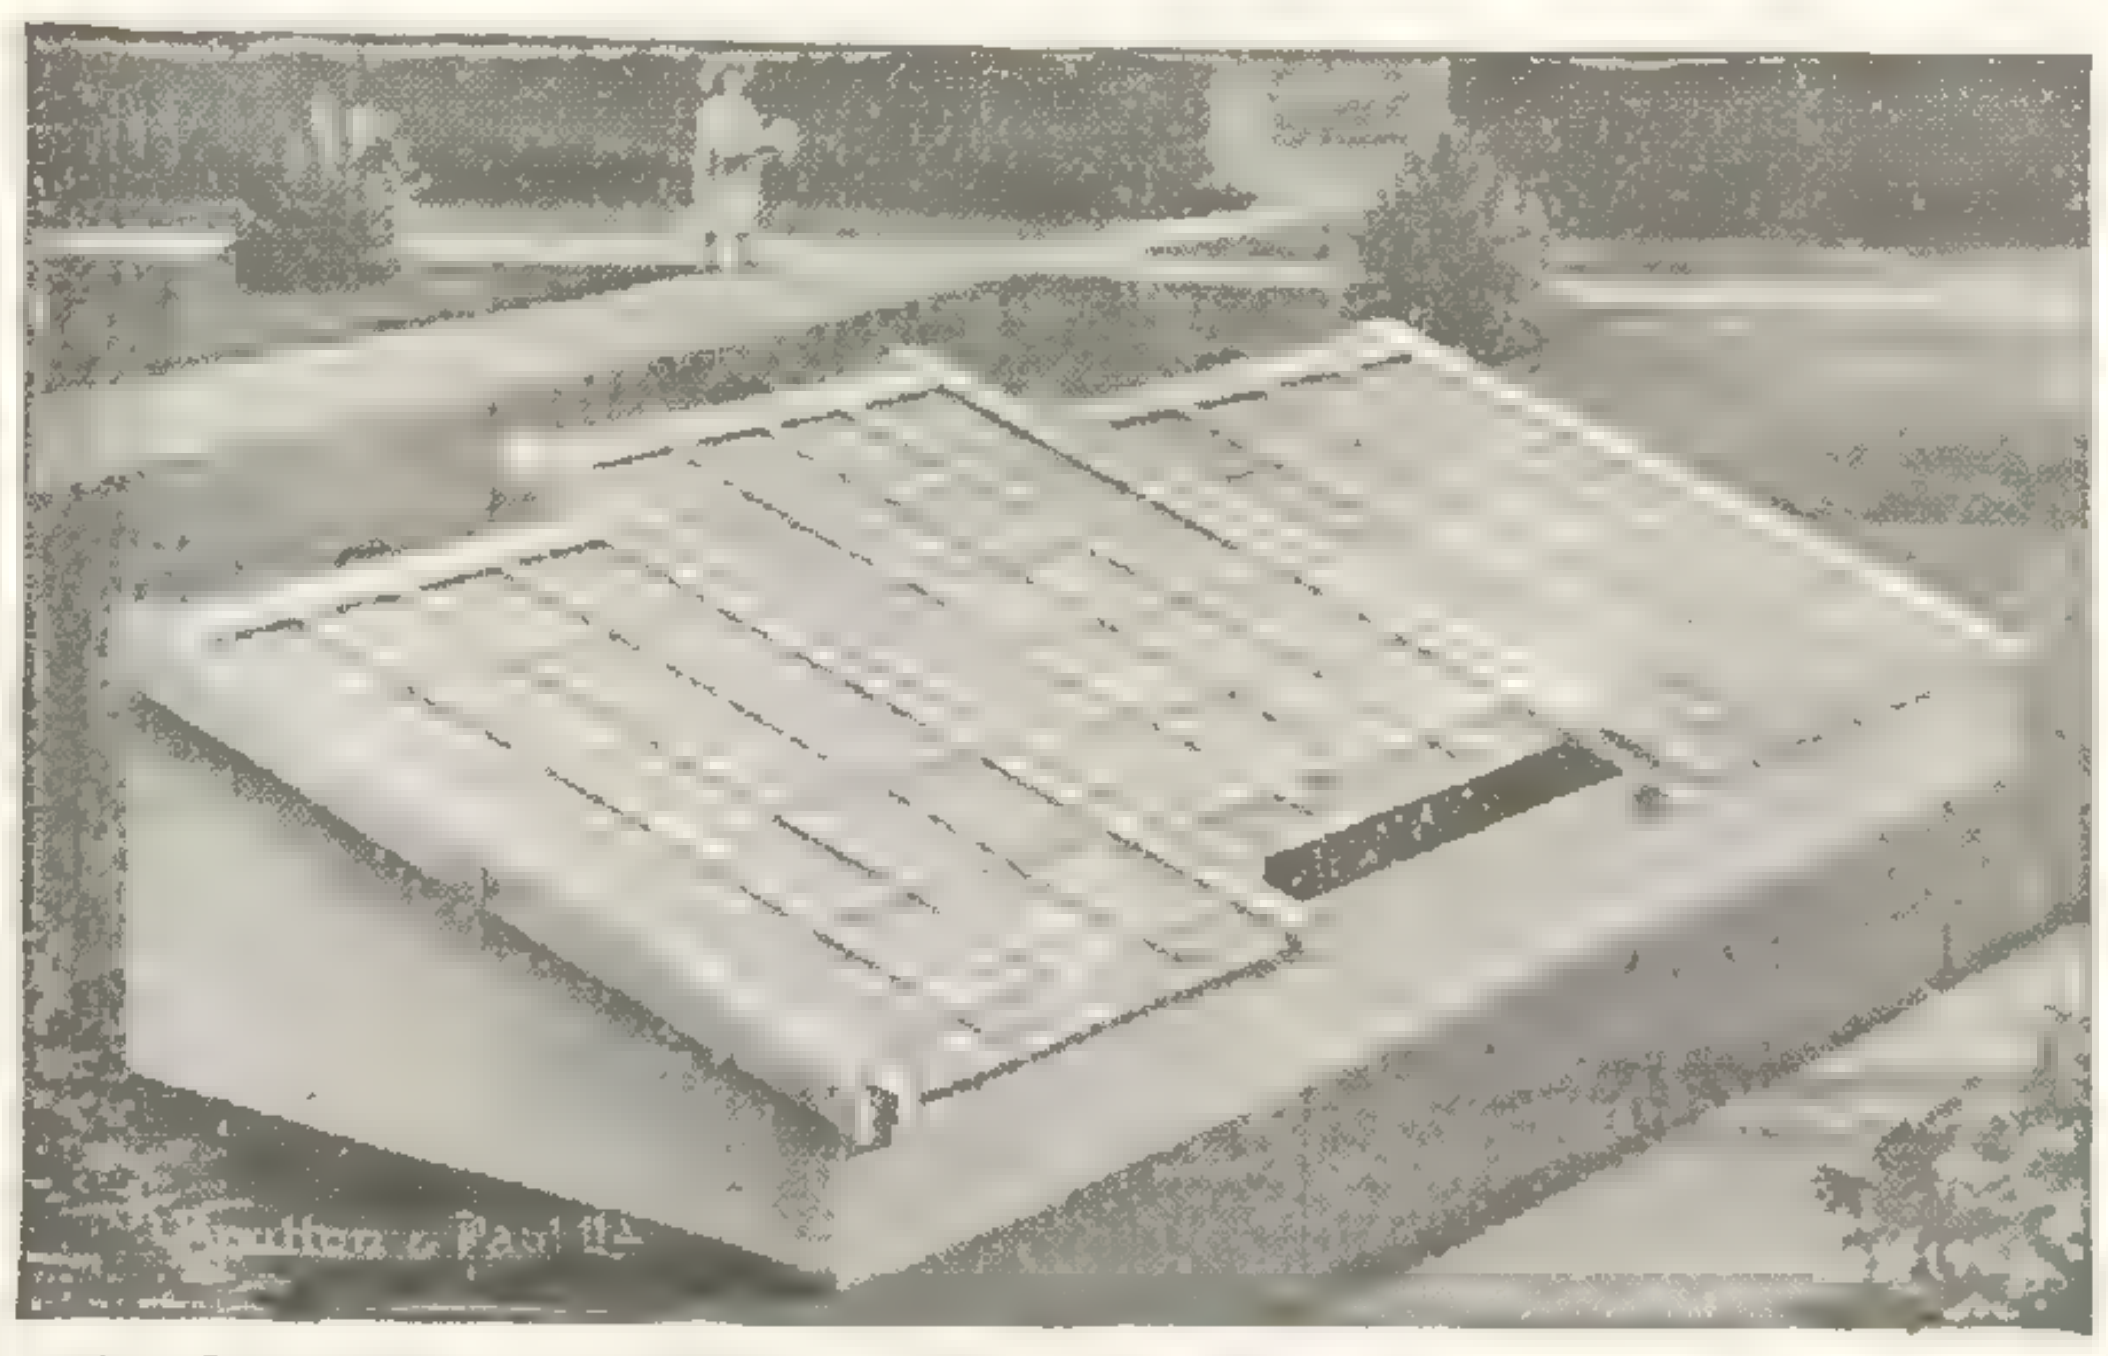


Ladies and Gentlemen waited upon by appointment.

CARRIAGE PAID on orders of **40**/- value to most Goods Stations in England.

HEATING APPARATUS installed in COUNTRY HOUSES, HORTICULTURAL & PUBLIC BUILDINGS.

No. 75.—MELON and CUCUMBER FRAME.

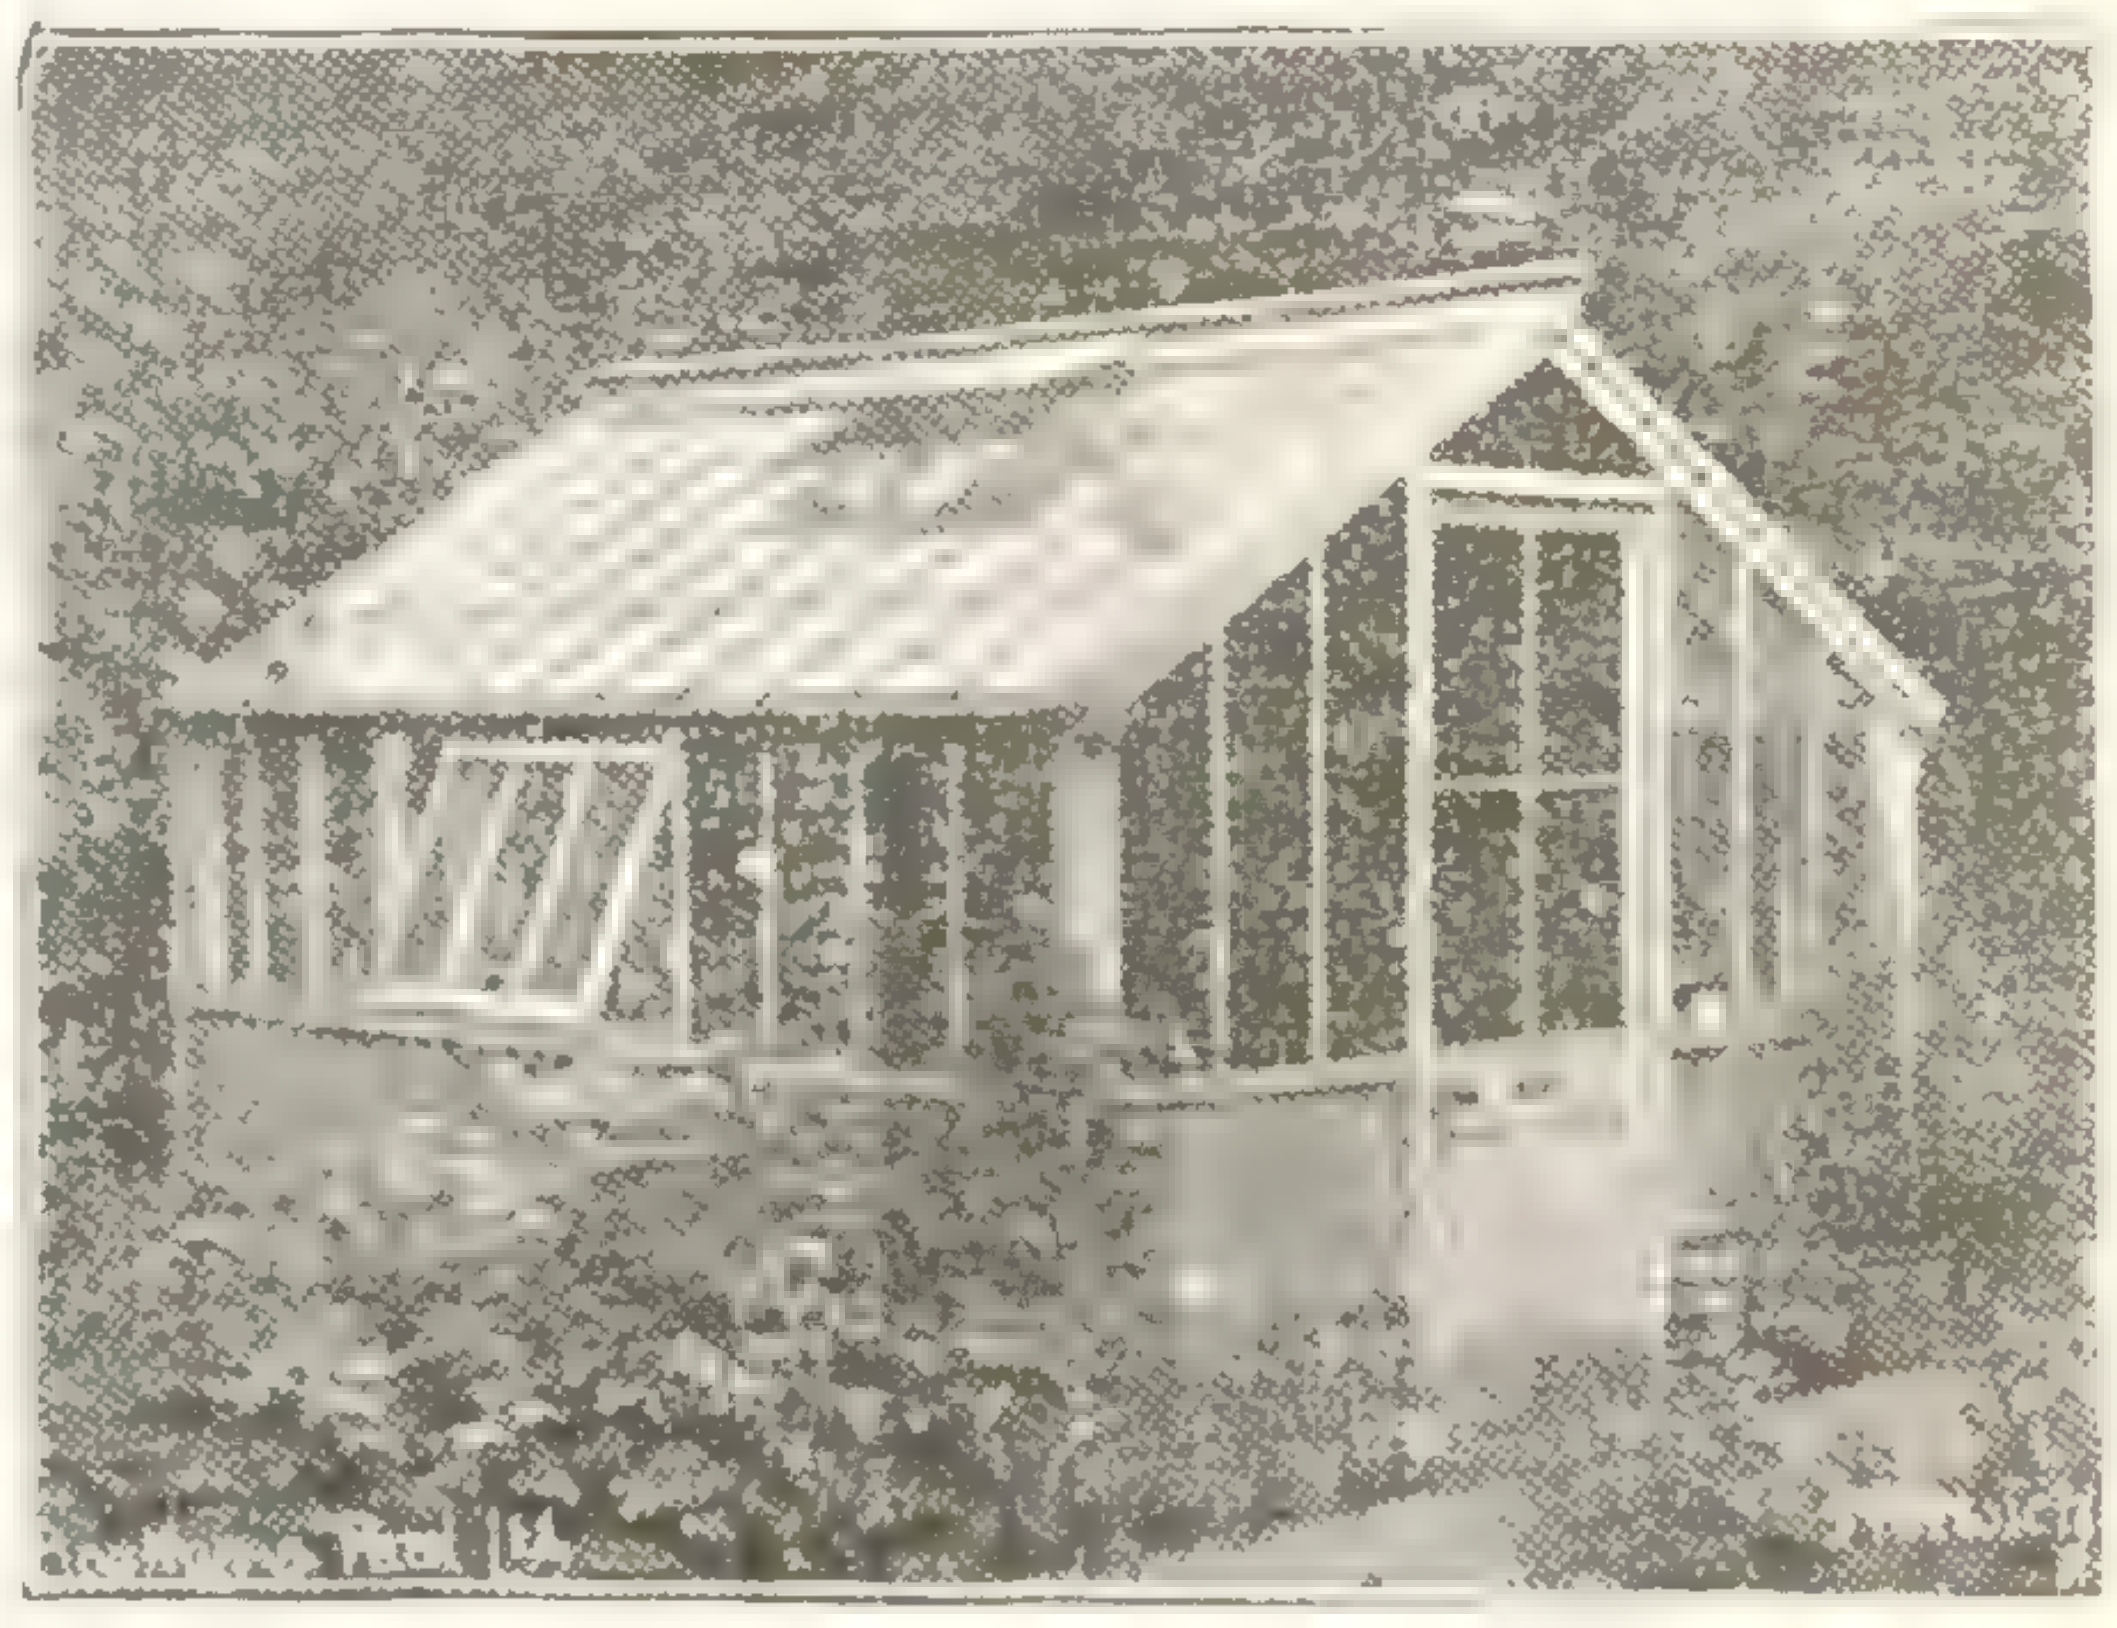


4ft. by 6ft. ... £2 0 0 | 8ft. by 6ft. ... 3 0 0
Painted three coats. Glazed with 21oz. glass.

No. 77.—VIOLET FRAME, 6ft. by 4ft. Similar to No. 75, with Two Lights... **35**/-

SEND FOR ILLUSTRATED CATALOGUES.

Every part of these Houses is thoroughly well made, painted three coats, GLAZED AT OUR WORKS WITH 21oz. GLASS and CARRIAGE PAID.



No. 49A.—Span, 10ft. by 8ft. £11 10 0
No. 47A.—Lean-to, 10ft. by 7ft. £9 10 0

All parts are numbered ready for easy re-erection by any handy man.

or glazed on one or both sides, and glazed tin boxes, are provided by appliance dealers for those who have but a small number of sections to deal with; where larger quantities are handled, the printed band holding on the two squares of glass will be found the best and most economical.

FARM WEEDS.—R. L. M., Ipswich: The Board of Agriculture and Fisheries has issued eight leaflets dealing with common farm weeds and their destruction. These are: "The Destruction of Charlock" (No. 63); "Weeds and Their Suppression" (No. 112); "Some Common Thistles" (No. 166); "Dodder" (No. 180); "Coltsfoot" (No. 194); "Meadow Saffron" (No. 222); "Broom Rape" (No. 226); and "Couch or Twitch" (No. 249). You may obtain all these leaflets, free of charge and post free, on application to the Secretary, Board of Agriculture, 4, Whitehall Place, London, S.W., and the letter of application so addressed need not be stamped. You could scarcely get the desired information cheaper!

HORTICULTURAL EXAMINATION PAPERS.—R. M. A., Godalming: The questions set by the Royal Horticultural Society at all the examinations held from 1893 to 1909 are now published in book form, and are of great value and interest to prospective candidates. The set can be obtained from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S. W., for 2s.

SWEET PEAS.—A. L., Beverley: Obtain "Sweet Peas and Their Cultivation" from the GARDENERS' MAGAZINE office, 148, 149, Aldersgate Street, London, E.C., post free for 1s. 2d., or 1s. 8d. (cloth binding).

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

R. C., Oxford.—Polygonum Baldschuanicum.

G. B. J., Truro.—1, Stapelia gigantea; 2, Thymus serpyllum; 3, Plumbago Larpentæ.

B. G., Eye.—1, Ligustrum chinensis; 2, Eleagnus pungens; 3, Olearia Haasti; 4, Cotoneaster frigida.

C. W., Shrewsbury.—1, Callicarpa purpurea; 2, Cotoneaster horizontalis; 3, Aster Delight; 4, Solidago californica.

N. A. W., Torrington.—1, Tamarisk gallica; 2, Arbutus Unedo; 3, Diplopappus chrysophyllus; 4, Solanum capsicastrum; 5, Solanum jasminoides.

W. H. C., Monmouth.—1, Pelargonium crispum; 2, Strobilanthes Dyerianus; 3, Sedum Sieboldi.

V. P., Hertford.—1, Odontoglossum crispum, poor form; 2, Cattleya Harrisonæ; 3, Odontoglossum gloriosum; 4, Sibthorpea europæa; 5, Cypripedium Actæus.

NAMES OF FRUIT.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

T. D. L., Whitby.—1, King of the Pippins; 2, Lane's Prince Albert.

L. M. S., Halstead.—1, Hambling's Seedling; 2, Ribston Pippin; 3, Mère de Ménage.

A. T. B., Bletchley.—1, Lane's Prince Albert; 2, Golden Noble; 3, Adam's Pearmain.

F. Y., Bideford.—1, Yorkshire Beauty; 2, American Mother; 3, Alfriston; 4, not in character.

G. S. D., Abergavenny.—1, Court Pendu Plat; 2, Beurre Bosc; 3, Beurre Diel; 4, Dumelow's Seedling; 5, Sturmer Pippin.

B. A. F., Newhaven.—1, Claygate Pearmain; 2, Beurre Clairgeau; 3, Pitmaston Duchess; 4, Marie Louise; 5, Cox's Orange Pippin; 6, Fearn's Pippin.

CATALOGUES RECEIVED.

C. KIEF AND SONS, LIMMEN, NEAR HAARLEM, HOLLAND.—The special features of this firm's English catalogue of bulbs are the extended descriptive lists of double and single hyacinths and tulips.

J. STORMONTH AND SON, KIRKBRIDE, CARLISLE.—This is a closely-printed descriptive catalogue of handy size, and one that includes a wide range of tuberous and fleshy-rooted plants as well as bulbs.

ALDERSEY AND MARSDEN JONES, TILSTON, MALPAS.—An interesting list of choice new sweet peas, raised at Aldersey Hall. These varieties are remarkable for their refinement of form and colour.

W. SEABROOK AND SONS, CHELMSFORD.—Although a well-illustrated and descriptive list of fruits occupies the larger part of the catalogue, roses are also included.

H. MERRYWEATHER AND SONS, LIM., SOUTHWELL, NOTTS.—A handy catalogue of fruits, roses, shrubs, etc. The new fruits offered include the Merryweather damson and Crimson Bramley's Seedling apple.

FRANK CANT AND CO., BRAISWICK NURSERIES, COLCHESTER.—A very complete catalogue of roses, freely illustrated. New varieties occupy a prominent place in the list.

JAS. VEITCH AND SONS, CHELSEA.—Four catalogues reach us from the Chelsea firm. The one devoted to fruit trees is capitally arranged and well illustrated. The rose catalogue is quite a work of art, and contains a very fine selection of varieties. Carnations and picotees furnish another list, but of special interest is the list of new hardy plants from Western China, introduced through Mr. E. H. Wilson.

FORTHCOMING ENGAGEMENTS.

VOL. LIV.—No. 3,027. SATURDAY, NOVEMBER 4, 1911.

THE GARDENERS' MAGAZINE.

The Season of the Golden Flower.

As will be seen by the reports that appear in another part of this issue, the exhibition season of the chrysanthemum has commenced, and it is satisfactory to have evidence at the shows that have been held that, notwithstanding the trying character of the weather experienced during the summer months, the blooms are likely, as a whole, to attain to a high state of development. Those who have taken a close interest in the exhibition aspects of the chrysanthemum and its cultivation, for a period, say, of thirty years, could hardly have failed to be much impressed by the quiet manner in which the present season has opened, as compared with the keen interest evinced in previous years in the possibilities of the competition in the leading classes at the great exhibitions, and in the chances of the more successful of the exhibitors of adding to the number of valuable challenge cups or to the balance at their bankers. There is still an interest in the chief competitions, but it is less pronounced, even in the case of those who fully appreciate the cultural skill displayed in the production of blooms in so high a state of development as to enable the grower to take a leading position in a keen contest. As regards the flower-loving community as a whole, there can be no question that chrysanthemum shows do not prove so attractive as was the case no farther back than ten years ago, and that the interest shown is of a decidedly local character. If this be so—and we have no doubt upon the point—there can be no question as to the large exhibition blooms, which have so long been the chief feature of chrysanthemum shows, being less highly esteemed by the general public. This is due in some degree to the practice which has so long obtained with many societies of giving undue encouragement to one class of chrysanthemums, instead of arranging the classes to ensure an adequate representation of the chief sections. The average visitor will undoubtedly make his way, on entering an exhibition, to the stands or vases of splendidly-developed blooms of Japanese varieties in competition for valuable prizes, and will linger long over them in admiring their graceful forms and attractive colourings. Having fully enjoyed their charms, he will turn to the other objects in the exhibition, and, we venture to suggest, derive but little pleasure from an inspection of the stands of blooms belonging to the same section, but of quite ordinary quality. Within the past few years some improvement has been effected in the allocation of prizes; and several other sections, notably the singles, have been staged in larger numbers and better condition. The falling off in the number of entries in some of the chrysanthemum classes is undoubtedly due to a considerable reduction in the numbers of these flowers grown under glass in the majority of gardens. For a comparatively long period after the introduction of the Japanese varieties there were but few flowers of their season that could properly be compared with them for decorative purposes; but there are now several classes that possess so high a degree of merit as to have proved formidable competitors. First in importance there are the perpetual-flowering carnations, which, it will be readily conceded, are of immense value for beautifying the plant house and the supply of flowers in a cut state for indoor decorations. Then there are the winter-flowering begonias which have been introduced within recent years, and are now sufficiently numerous to form a large group of much value for the production of bright colour effects in the warm conservatory during the dullest period of the year. In addition to these new and highly attractive classes of autumn and winter-flowering plants, the bulbs and hardy shrubs retarded in accordance with modern methods have to be reckoned with; for, owing to the facility with which they can now be had in bloom during the autumn, they enter into a strong competition with the chrysanthemum. In a consideration of the facts bearing on the decline in popularity of blooms of the type which for a number of years have so greatly predominated at exhibitions, we see no cause for despondency with regard to the future of the chrysanthemum. The various sections of the flower may be expected to undergo considerable changes in their relation to the public taste, precisely in the same way as they have done in the past; but there is full justification for the belief that the chrysanthemum will, taking it collectively, continue to occupy a prominent position in gardens. It should be remembered in connection with this point that while the big exhibition blooms have been steadily declining in favour, there has been a remarkable development in the early-flowering varieties, and a great increase in their popularity. As one result of the increase in the number of first-class varieties blooming before the opening days of November the cultivation of this section for market has become an industry of some importance. Another result has been their greatly extended culture in private gardens for the production of bright effects during September and October; and it is reasonable to assume that this extension will increase in rapidity as the merits of the finer varieties become fully recognised. If there is no cause for anxiety with regard to the chrysanthemum in relation to the garden, there is some cause for apprehension as to the future of a large proportion of the November exhibitions. There is not so much a danger of collapse as of their failing to receive sufficient support to admit of their being maintained in a high degree of efficiency, and thus afford those residents of the respective districts who are interested in gardening an opportunity of meeting once a year amid pleasant surroundings. There is no occasion to abolish the large exhibition

MR. JOHN E. DAVIS.

blooms, but in many instances the number of classes should be reduced with a view to giving more encouragement to other sections, and thus ensure a greater diversity of colour and form. Especially deserving of encouragement are the single and decorative varieties, which, tastefully arranged in vases of moderate size, prove highly attractive. We suggest also that classes should be provided, with comparatively liberal prizes, for the carnations referred to, of which there are now so many beautiful varieties, and also for begonias flowering in winter; and the classes for the latter should be so arranged as to secure an adequate representation of the several types. There are other plants that might be encouraged with advantage; and the object should be not so much to hold a show of chrysanthemums as a winter exhibition in which these flowers will be prominent, and other subjects, including fruits and vegetables, belonging to the season be adequately represented.

Mr. John E. Davis, who has charge of the beautiful gardens of Ballathie, the Perthshire seat of Colonel Richardson, takes high rank among the many able exponents of the gardening art who pursue their avocations in the district of which the fair city of Perth is the centre. Deservedly high as is Mr. Davis's reputation as a practical horticulturist, he disclaims any idea of being a specialist; and, writing with a personal knowledge of the Ballathie gardens, in which his generous employer takes so keen an interest, we have no hesitation in stating that we are in full agreement with him on this point, and should regard him rather as occupying a prominent position among those who are usually described as all-round gardeners. Mr. Davis is certainly equally at home in all departments of a great garden; for, whether in plant or fruit house, or flower or kitchen garden, there is ample evidence of judgment and cultural skill of a high order; and in many a keen contest at Edinburgh both ornamental plants and vegetables have brought honours to the Ballathie gardens. For some years Mr. Davis has been a most successful exhibitor of groups of plants arranged for effect, and of collections of vegetables at the Royal Caledonian Horticultural Society's autumn exhibitions. At the Scottish Horticultural Association's shows in November the Ballathie chrysanthemums have won numerous awards, including several gold and silver medals offered by the National Chrysanthemum Society, and the Centenary Cup. While giving increased attention to hardy fruits and vegetables, Mr. Davis has been especially successful in the cultivation of hardy and half-hardy annuals, and of the fine borders of these, relieved by columns of sweet peas, we have a very distinct recollection. Equally noteworthy are the great breadths in the ample borders of antirrhinums, violas, sweet williams, and nemesias, the last named being grown and flowered in a manner that is by no means usual, and form a feature that at once arrests the attention of visitors. Previous to taking charge of the gardens of Ballathie, Mr. Davis was head gardener for some eight years to J. E. Barker, Esq., K.C., at Brooklands, Derbyshire, and here also he gave ample evidence of his ability and knowledge of all that relates to the garden and its management.

Apples and Pears at R.H.S. Meetings. The Rev. W. Wilks writes: The Chairman of the Royal Horticultural Society's Fruit Committee wishes to call the attention of those sending apples and pears for awards to the fact that at least six fruits of each variety are required by the rules, and that all specimens should be in good usable condition either for cooking or dessert at the time of sending. Each variety should be accompanied with full particulars as to the position in which it is grown (wall culture or otherwise), and also the form of tree, and, if possible, its origin, with full notes as to cropping, keeping, and age of tree. Otherwise the examples cannot be dealt with. For instance, it is useless to send up apples which will not be at their best till March in October and November.

His Majesty King George V. has just communicated to the directors of the Royal International Horticultural Exhibition, through Colonel Sir George Holford, K.C.V.O., his intention to open the exhibition on May 22, 1912, at 12 noon.

Ghent Quinquennial, 1913.—The preparations for the International Horticultural Exhibition that will be held by the Société Royale d'Agriculture et de Botanique de Gand in 1913 are in an advanced state, and these suggest that it will be at least equal to the most important of the horticultural gatherings that have been held in Ghent since the foundation of the society. The exhibition will be held in the new Palais de l'Horticulture et des Fêtes, which, judging from the plans now before us, is admirably adapted to flower shows of the first class. This magnificent building will have a superficial area of 30,000 metres and cost 1,750,000 francs. It will contain a hall with a superficial area of 14,000 metres, for plants not requiring artificial heat at the time of exhibition, and a smaller hall with a superficial area of 6,000 metres that will be heated and otherwise fitted for the accommodation of plants from tropical regions. As at previous quinquennials, special encouragment will be given new plants, the schedule containing twenty-one classes. In addition to the ordinary prizes in the several classes, the jury will have at their disposition a special prize to be awarded to the plant or group of plants presenting the greatest merit. The section devoted to orchids is of special interest as evidence of the increased importance of orchids in Belgium. A quarter of a century ago less than a dozen classes were provided for orchids, and in the schedule of the exhibition to be held in 1913 they number eighty-four.

Horticultural Club.—The next house dinner of the club will take place on Tuesday, November 7, at the Hotel Windsor, Victoria Street, S.W., when Mr. Reginald A Malby will give a lecture on "A Miniature Alpine Garden," illustrated by lantern slides.

Heating the Waverley Market, Edinburgh.—At last the Edinburgh Corporation have adopted a scheme of heating for the Waverley Market, and Messrs. Mackenzie and Moncur, Ltd., are at present working day and night in order to accomplish the task of handing over the installation in working order before November 13. Competitors and exhibitors at the Chrysanthemum Show and other winter exhibitions will be glad to hear of this, and the general public will now have the satisfaction of knowing that in future they will be able to visit these exhibitions under much more comfortable conditions than they have hitherto done in severe weather. The system which has been adopted is what is known as the "Plenum," and in its essential features is the same as that in operation in the Houses of Parliament. The steam used for heating the air which will be driven into the building will be generated in a Babcock and Wilcox water-tube boiler, which is to be placed in an underground chamber outside the building. The heating chamber, to which the steam will be conveyed from the boiler by piping, will be placed immediately inside the market house. In this will be placed a series of 75 coils of $1\frac{1}{4}$in. piping, in flat sections resembling gridirons, placed parallel to each other, and over this battery of 8,000 feet of steam-heated piping the air will be driven into the building by a powerful fan worked by a 40-horse power electric motor. This fan will be capable of forcing 5,000,000 cubic feet of heated air into the building per hour, and it can be used in hot weather for driving in fresh air for ventilation of the building. From the heated chamber the air will be conveyed into the building by a large duct, placed at the level of the roof girders, and thence it will be carried in smaller ducts to all parts of the hall. The cost of the installation will be over £2,000.

Nomenclature of Cape Pelargoniums.—The council of the Royal Horticultural Society has been asked to endeavour to obtain an agreement on the nomenclature of what are commonly known as Cape pelargoniums. The only practical way known to the council is to invite all growers of these plants to at once send cuttings (rooted or otherwise), with the name known to the sender, by post to the Superintendent, R.H.S. Gardens, Wisley, Ripley, Surrey. They will be potted up, and next year be compared with each other and with Herbarium specimens and printed records. No zonals, or show, or French pelargoniums should be sent; only these known as "Cape." As the nomenclature of this interesting group of pelargoniums is much confused, we hope that growers will co-operate with the council of the Royal Horticultural Society in placing it on a satisfactory basis.

N.R.S. Catalogue of Roses.—The new official catalogue of roses published by the National Rose Society has been issued to the members, and, unless we are much mistaken, will be highly appreciated by them as a trustworthy guide to the distinguishing characteristics of the finest of the varieties in cultivation, and in making selections for various purposes.

National Sweet Pea Society.—This society will hold its annual meeting on Friday, December 8, at the Hotel Windsor, Victoria Street, Westminster, at two o'clock. Notices of new rules or alteration of rules should reach the hon. secretary, Mr. C. H. Curtis, on or before Friday. November 17. The annual meeting will be followed by a dinner at six o'clock, and this in turn will be followed by a sweet pea conference to commence at seven o'clock, and at which the following subjects will be dealt with: "Sweet Pea Diseases," by Mr. Fred Chittenden, F.L.S., Director of the Wisley Laboratory; "Packing Sweet Peas for Market," by Mr. Thomas Page, of Hampton; and "Packing Sweet Peas for Exhibition," by Mr. Thomas Stevenson, of Addlestone.

Important to Secretaries of Horticultural Societies. — The edition of the "Gardening Year Book" for 1912 is in an advanced stage of preparation, and secretaries of botanical and horticultural societies and gardeners' associations are earnestly requested to return the notices properly corrected which they have received, with as little delay as possible, so that any changes which have been made in the names or addresses of the secretaries may be duly recorded in the list of Horticultural and Botanical Societies of the United Kingdom. We shall also be glad to receive from our readers notification of any such changes as have come under their notice.

NATIONAL CHRYSANTHEMUM SOCIETY'S SHOW.

The premier chrysanthemum society held its exhibition at the Crystal Palace on November 1, 2, and 3, and the opening day was a delightful one. The show was of great extent and rather finer than that held in 1910. The competition of many of the classes was not over keen, but the blooms staged were of excellent quality. Table decorations were better than usual, and trade exhibits were exceptionally fine and numerous, making in themselves a wonderfully brilliant and interesting exhibition. It is a pity that in some of the "display" classes there is not a keener interest, as such exhibits are very attractive. The affiliated societies did well, and each exhibit in their special class was of high merit.

Mr. Norman Davis was awarded the gold medal offered by Messrs. Clay and Son, Stratford, for the best non-competitive display in the show; and Mr. Hunt, Ashstead Park Gardens, Ashstead, secured the Dean Memorial Gold Medal with his exhibit of three dozen incurved blooms.

DISPLAY OF CHRYSANTHEMUMS FROM THE DULWICH HORTICULTURAL SOCIETY.
This exhibit won the Trophy open to competition among societies affiliated with the National Chrysanthemum Society at the Crystal Palace, on November 1, 2, and 3.

HOLMES CUP CLASSES.

The Holmes Memorial Cup for three dozen incurved blooms, distinct, was won by Mr. G. Hunt, gardener to Pantia Ralli, Esq., Ashstead Park, Epsom, with a set that included some fine flowers, but also some weak ones; his best were of Duchess of Fife, Romance, Mrs. G. Judson, Clara Wells, Mrs. C. Crooks, Miss E. Holding, Embleme Poitevine, W. Biddle, Godfrey's Eclipse, C. H. Curtis, and Edwin Thorp; Mr. W. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, came second, and Mr. T. J. Broom, gardener to Miss Langworthy, Gays House, Holyport, came third.

Only two competitors came forward to fight for the Holmes Memorial Cup for forty-eight Japanese blooms, distinct, and Mr. C. Moore, gardener to Mrs. W. Clash, Frensham Place, Farnham, won the famous cup. His flowers were fine, clean, and bright, and the very best were J. Lock, Mrs. C. H. Totty, Margaret Smith, Mr. Charles Beckett, Miss E. Green, Mrs. F. C. Stoop, Master David, A. S. Bott, D. B. Crane, J. W. Molyneux, Reg. Vallis, Francis Jolliffe, F. S. Vallis, Hon. Mrs. Lopes, and Duchess of Sutherland. Second prize fell to Mr. W. Mease, Downside Gardens, Leatherhead, who had capital blooms of King Edward VII., Reg. Vallis, Hon. Mrs. Lopes, Mrs. C. Penford, Rose Pockett, and Mrs. A. T. Miller.

LARGE VASE CLASSES.

Two exhibitors came forward in the class for a dozen vases of Japanese blooms, three flowers of one variety in each vase. First prize was won by Mr. A. Chandler, Colon House Gardens, Rugby, who led with large examples of Frances Joliffe, James Lock, George Hemmings, Master David, Mrs. H. Thornton, G. J. Bruyard, Master James, Mrs. F. C. Stoop, Eclipse, Evangeline, Algernon Davis, and Reginald Vallis; the second prize fell to Mr. W. Mease, Downside Gardens, Leatherhead.

Mr. G. Hunt scored for a dozen vases of incurved blooms distinct, three flowers of each, with big well-developed examples of Edwin Thorp, Buttercup, Mrs. G. Judson, C. H. Curtis, W. H. Thorp, Godfrey's Eclipse, Romance, Clara Wells, Duchess of Fife, Margaret Brown, Embleme Poitevine, and Miss Nellie Southam; the second prize was won by the veteran grower, Mr. W. Mease.

JAPANESE BLOOMS.

For twenty-four Japanese blooms distinct the premier award (President's Prize) fell to Mr. H. Lloyd, gardener to Captain C. Wiener, Ewell Castle, Ewell, for a good even set that included Reg. Vallis, Rose Ellis, Frances Jolliffe, Sir Albert Rollit, J. Lock, Superb, Bessie Godfrey, Mrs. F. C. Stoop, Mrs. A. T. Miller, and Melchet Beauty; second prize fell to Mr. W. Rigby, gardener to the Rev. Cooper Marsden, Borstaldine, Bickley, and third to Mr. A. Chandler, gardener to A. James, Esq., Coton House, Rugby. There were six competitors.

Mr. Mease had the best vase of six white Japanese blooms, and he scored with grand examples of the beautiful Mrs. A. T. Miller: for six blooms of a yellow Japanese variety, Mr. C. Moore, Frensham, led with very large specimens of the Hon. Mrs. Lopes, with Mr. H. J. Hedges, Kirkdale Nursery, Sydenham, second. For six blooms of any other colour, Mr. G. Mileham secured the chief award with James Lock, Mr. H. J. Hedges coming second with Mrs. George Mileham.

In the class for a dozen Japanese blooms distinct, arranged with suitable foliage on a space of 5ft. by 3ft., there were five competitors, and the class proved a very attractive one. First prize was well won by Mr. W. Mease, who had grand blooms of Hon. Mrs. Lopes, Reg. Vallis, Countess of Granard, J. Lock, White Queen, Mrs. A. T. Miller, Kara Dow, Duchess of Sutherland, Walter Jinks, Beatrice May, Rose Pockett, and Miss Annie Nicoll; Mr. A. Smith, The Convent Gardens, Roehampton, second, and Mr. Rigby, Bickley, third.

SINGLE AND POMPON VARIETIES, ETC.

Competition was poor in the class for a table of single chrysanthemums; first prize fell to Mr. F. G. Bealing, Bassett, Southampton, who had large vases of small and rather rough blooms of Mary Richardson, the Pagram varieties, etc. There was only one entry for a display of singles, and this was disqualified because it failed to meet the schedule specifications.

Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham, was the only exhibitor of a display of single and pompon varieties arranged on a ground space of 72 sq. ft. Mr. Howe used Mary Richardson, Ladysmith, and other sorts freely, with a few bush plants of yellow pompon varieties, banking these with crotons, bamboos, and ferns, and making up a bright exhibit.

One competitor came forward with six vases of pompons, and this was Mr. T. J. Broom, to whom a first prize was granted; he showed delightful little flowers of Golden Fleece, Rosinante, Mdlle. Elise Dordan, Sunset, President, and Katie Mannings. Apparently only one exhibitor staged four vases of large anemones, and to this set, from Mr. T. J. Broom, a second prize was awarded.

First prize for a dozen bunches of market chrysanthemums was capitally won by Messrs. Cragg, Harrison, and Cragg, Heston, with grand dozens of Mrs. Roots, Freda

Bedford, D. Ingamells, Phœbe, E. Cox, Heston Bronze, Crimson King, H. W. Thorp, Moneymaker, Embleme Poitdevine, Mary Thorp, and Bronze McNiece; Mr. F. Brazier, Caterham, second.

The best dozen incurved blooms came from Mr. W. Mease, with Mr. T. J. Broom, gardener to Miss Langworthy, Gays House, Holyport, second. For six incurved blooms, one variety, Mr. W. Mease was to the front with very large but somewhat rough flowers of Buttercup; Mr. G. Mileham, gardener to A. T. Miller, Esq., Emlyn House, Leatherhead, second, with Buttercup; and Mr. T. J. Broom third with Clara Wells.

AMATEURS.

In the amateurs' section, Mr. W. Rigby led for a dozen Japanese blooms from among six competitors, and he was followed in order by Mr. W. Trowell, gardener to D. Link, Esq., Fairlight, Beckenham; and Mr. J. W. Stevens, gardener to W. H. Stone, Esq., Donnington, Sydenham. Mr. J. King, East View, Hendon, scored for a dozen incurved blooms, with Mr. T. Sharpe, Railway Terrace, Greenhithe, second.

In another division, Mr. T. Sharpe gained a first prize with a capital set of twelve Japanese blooms, his Reg. Vallis, Mrs. G. Mileham, and Master David being very fine; Mr. B. E. Davies, White Lodge, Biddenden, second; and Mr. J. King third.

In the smaller amateurs' classes leading prizewinners were Mr. J. Vanstone, gardener to W. G. Richardson, Esq., Hollymead, Tulse Hill; Mr. W. Rigby; Mr. R. Gladwell, gardener to A. Goschen, Esq., Tennison Road, Norwood (who showed a fine half dozen of Reg. Vallis); Mr. C. H. Martin, gardener to Mrs. Langton, Roymead, Hendon; Mr. A. Dyer; Mr. J. Luscombe, St. Faith's Road, West Norwood; Mr. B. E. Davies; Mr. T. Sharpe, Stone, Greenhithe; Mr. J. King, East View, Hendon; and Mr. G. Moorman, Hampton Court Palace.

AFFILIATED SOCIETIES.

There were three entries in the National competition open to societies in affiliation with the N.C.S. This was for a display of chrysanthemum blooms, to represent not fewer than four sections of the flower, arranged with suitable plants and foliage on a table 16ft. by 6ft. The Challenge Trophy fell on this occasion to the Dulwich Horticultural and Chrysanthemum Society, which arranged its flowers boldly in stands, baskets, and vases, in association with fern fronds and autumn foliage. There were grand stands of big Japanese blooms, and smaller exhibits of incurved flowers, while the stands of singles and the baskets of decorative sorts were delightfully set up. The second prize was won by the Sevenoaks Gardeners' Chrysanthemum Society, with a very graceful and effective contribution that had less of chrysanthemums, but almost as much of elegance as the first prize collection. The Sydenham District Horticultural Society came third.

FLORAL DECORATIONS.

In the open class for dinner-table decorations of chrysanthemums, yellow and bronze-coloured flowers only to be used, the leading award was given to Mrs. A. Robinson, Norhyrst, Park Hill, Carshalton. The arrangement of moderate-sized flowers was very tasteful, tinted autumn foliage being skilfully used to set off the blooms. Mr. T. W. Stevens, gardener to W. H. Stone, Esq., Donnington, Laurie Park, Sydenham, was second with a more formal arrangement, Mr. A. W. Trossell, 12, The Parade, Beckenham, coming third. The class was a strong one of some sixteen entries, but there was a certain degree of monotony in the whole display.

In the other table class, admitting any other coloured chrysanthemums, Mr. T. W. Stevens scored well with a nice arrangement, in which the palest of pinks contrasted with lively crimson. Mrs. Robinson followed with mauve and white flowers, Mr. A. W. Trossell coming third.

Only one entry was staged in the class for two vases of pompon or anemone pompon varieties, Mr. L. Lawrence, Shoreham Cottage Gardens, Shoreham, near Sevenoaks, being awarded first prize. For one vase of singles, Mr. M. E. Mills, gardener to F. Lloyd, Esq., Coombe House, Croydon, scored with a great vase of well-grown flowers set off with withered bracken and asparagus. Mr. L. Lawrence was second with a much smaller vase, Mrs. W. Maslin, Ongar Hill Cottages, Addlestone, being third out of five entries. Autumn foliage and berries arranged in a basket made quite an attractive class, the winning exhibit, staged by Mrs. Brewster, 12, St. Peter's, Canterbury, being composed of open pods of Iris fœtidissima, Physalis Alkekengi, Clematis vitalba fruits, statice, Honesty, etc. Mr. L. Lawrence came second with a tastefully-arranged basket of berries and bracken, third prize going to Mrs. A. R. Bide, Highlands, Farnham.

A hand basket of chrysanthemums for table was required in a class confined to lady members only, the winner being Mrs. G. Davis, 10, Crystal Palace Station Road, Upper Norwood, who used the ever popular yellow and bronze colours to good purpose. Mrs. A. Robinson, Carshalton, was a capital second, and Mr. A. R. Bide third, with nice blooms of the popular Rayonante well poised in a gilded basket.

The amateurs' single vase class for five Japanese blooms found Mr. W. Passey, gardener to Captain C. D. Clark, Shortlands, at the head of the list, with a nice vase of Mrs. A. T. Miller; second went to Mr. A. Dyer, gardener to E. Wood, Esq., The Tyrol, Church Road, Upper Norwood, his variety being F. S. Vallis; five blooms of a seedling came third, the exhibitor being Mr. J. W. Harrison, gardener to R. Girvin, Esq., Ashbourne, Laurie Park, Sydenham. Mr. A. Dyer won a good first for one vase of decorative blooms, showing some capital incurves and elegant singles; Mr. G. Bowyer, gardener to P. Dawson, Esq., Sydenham, showed Rayonante and a good white for second place, third going to Mr. J. W. Harrison. Mr. A. Dyer again led the way for a vase of singles, showing disbudded flowers of capital quality; Mr. W. Trafford, 15, Brook Street, Leek, Staffs, was second; and Mr. J. W. Harrison third.

FRUIT.

Four entries were staged in the class for three bunches of white grapes, the winner being Mr. E. C. Wickens, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill; second being awarded Mr. J. Shelton, gardener to Lord Hillingdon, Wildernesse, Sevenoaks; and third to Mr. W. Lintott, gardener to Sir Walpole Greenwell, Bart., Marden Park, Caterham. Mr. Wickens scored for three bunches of Gros Colmar; and Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham, led for three bunches of any other black variety with Alicante; second going to Mr. W. Lintott; and third to Mr. Shelton.

In the pear classes Mr. A. Basile, Woburn Park Gardens, Weybridge, led easily for six dishes, with Mr. W. Lintott second, and Mr. Paulley, Brigstock Road, Thornton Heath, third. For six dishes of apples Mr. Basile scored with grand dishes of Bismarck, Emperor Alexander, Lady Henniker, Mère de Ménage, Newton Wonder, and Bramley's Seedling; Mr. W. Lintott second; and Mr. C. Harris, The Grove, Watford, third..

NEW VARIETIES.

First-class Certificates were awarded: To Mrs. Percy Wiseman, a primrose incurved, from Mr. P. Wiseman, Woodham Walter; to Heston Bronze, a market variety, from Messrs. Cragg, Harrison, and Cragg, Heston; to Celia, a yellow single, from Messrs. Cragg, Harrison, and Cragg; to Mrs. John Peed, a bright yellow single, from Messrs. J. Peed and Son, West Norwood; to Caterham Bronze, a single, from Mr F. Brazier, Caterham; to R. G. Burge, a white single, from Mr. P. Ladds, Swanley Junction; to Mrs. Andrew Walker, a rich chestnut Japanese, from Messrs. W. Wells and Co., Merstham; to Miss Margaret Walker, a golden-bronze single, from Messrs. W. Wells and Co.; to Charles Dickens, a golden-yellow single, from Mr. Norman Davis.

NON-COMPETITIVE.

Several very fine exhibits, composed wholly, or almost wholly, of chrysanthemums, were staged, and these formed a grand feature of the exhibition. In the centre of the Palace Mr. Philip Ladds, Bexley, Kent, arranged a huge circular group, and in the middle he put up about a dozen enormous bouquets of fine blooms of prominent Japanese and reflexed market varieties, such as Crimson King, Freda Bedford, Miss L. Thorne, Mrs. A. T. Miller, Rayonnante, etc. Under these were palms and ferns, and dwarf pot chrysanthemums, while, forming a broad margin all around were low vases of blooms, associated with ericas, spiræas, and ferns, with here and there a tall vase of carnations, the whole edged with maidenhair ferns.

Mr. H. J. Jones, Lewisham, filled a large space in front of the orchestra with a magnificent exhibit of flowers arranged in stands of varying height, and in baskets and vases of various sizes. Palms, ferns, and autumn-tinted foliage were freely and ably used to set off the flowers to fullest advantage. There were about sixty stands, vases, and baskets filled with large blooms, and in nearly every case only one variety was used in each receptacle. In some of the stands there were as many as two dozen flowers. A few of the varieties that were conspicuous in this fine exhibit were Mrs. Williams, Mdme. Albert Hall (a new yellow incurved), Miss L. Thorne.

Another splendid contribution was that from Mr. Norman Davis, Framfield, Sussex, who put up large sheaves of fine flowers, arranged over dwarf-flowering plants and single varieties. Very fine were the bold masses of Countess of Grenard, Mrs. C. H. Totty, December Gold, White Queen, Norman Davis, and Lady Talbot, while the grand single white, named Mensa, was represented by two fine vases. Baskets of single varieties added grace to the whole, and the pretty outline of the group was greatly admired. It was interesting to notice that Mr. Davis showed a few flowers each of King of the Crimsons and Progne, both probably upwards of half a century old.

Messrs. Hobbies, Lim., Dereham, contributed a bright collection of collarette, pæony-flowered, and cactus dahlias, and a large group of weeping standard roses and late rose blooms. Plumose nephrolepises and a rare collection of adiantums came from Messrs. H. B. May and Sons, Edmonton, and were greatly admired. Ornamental trees and shrubs with variegated foliage were extensively displayed by Mr. David Russell, Brentwood.

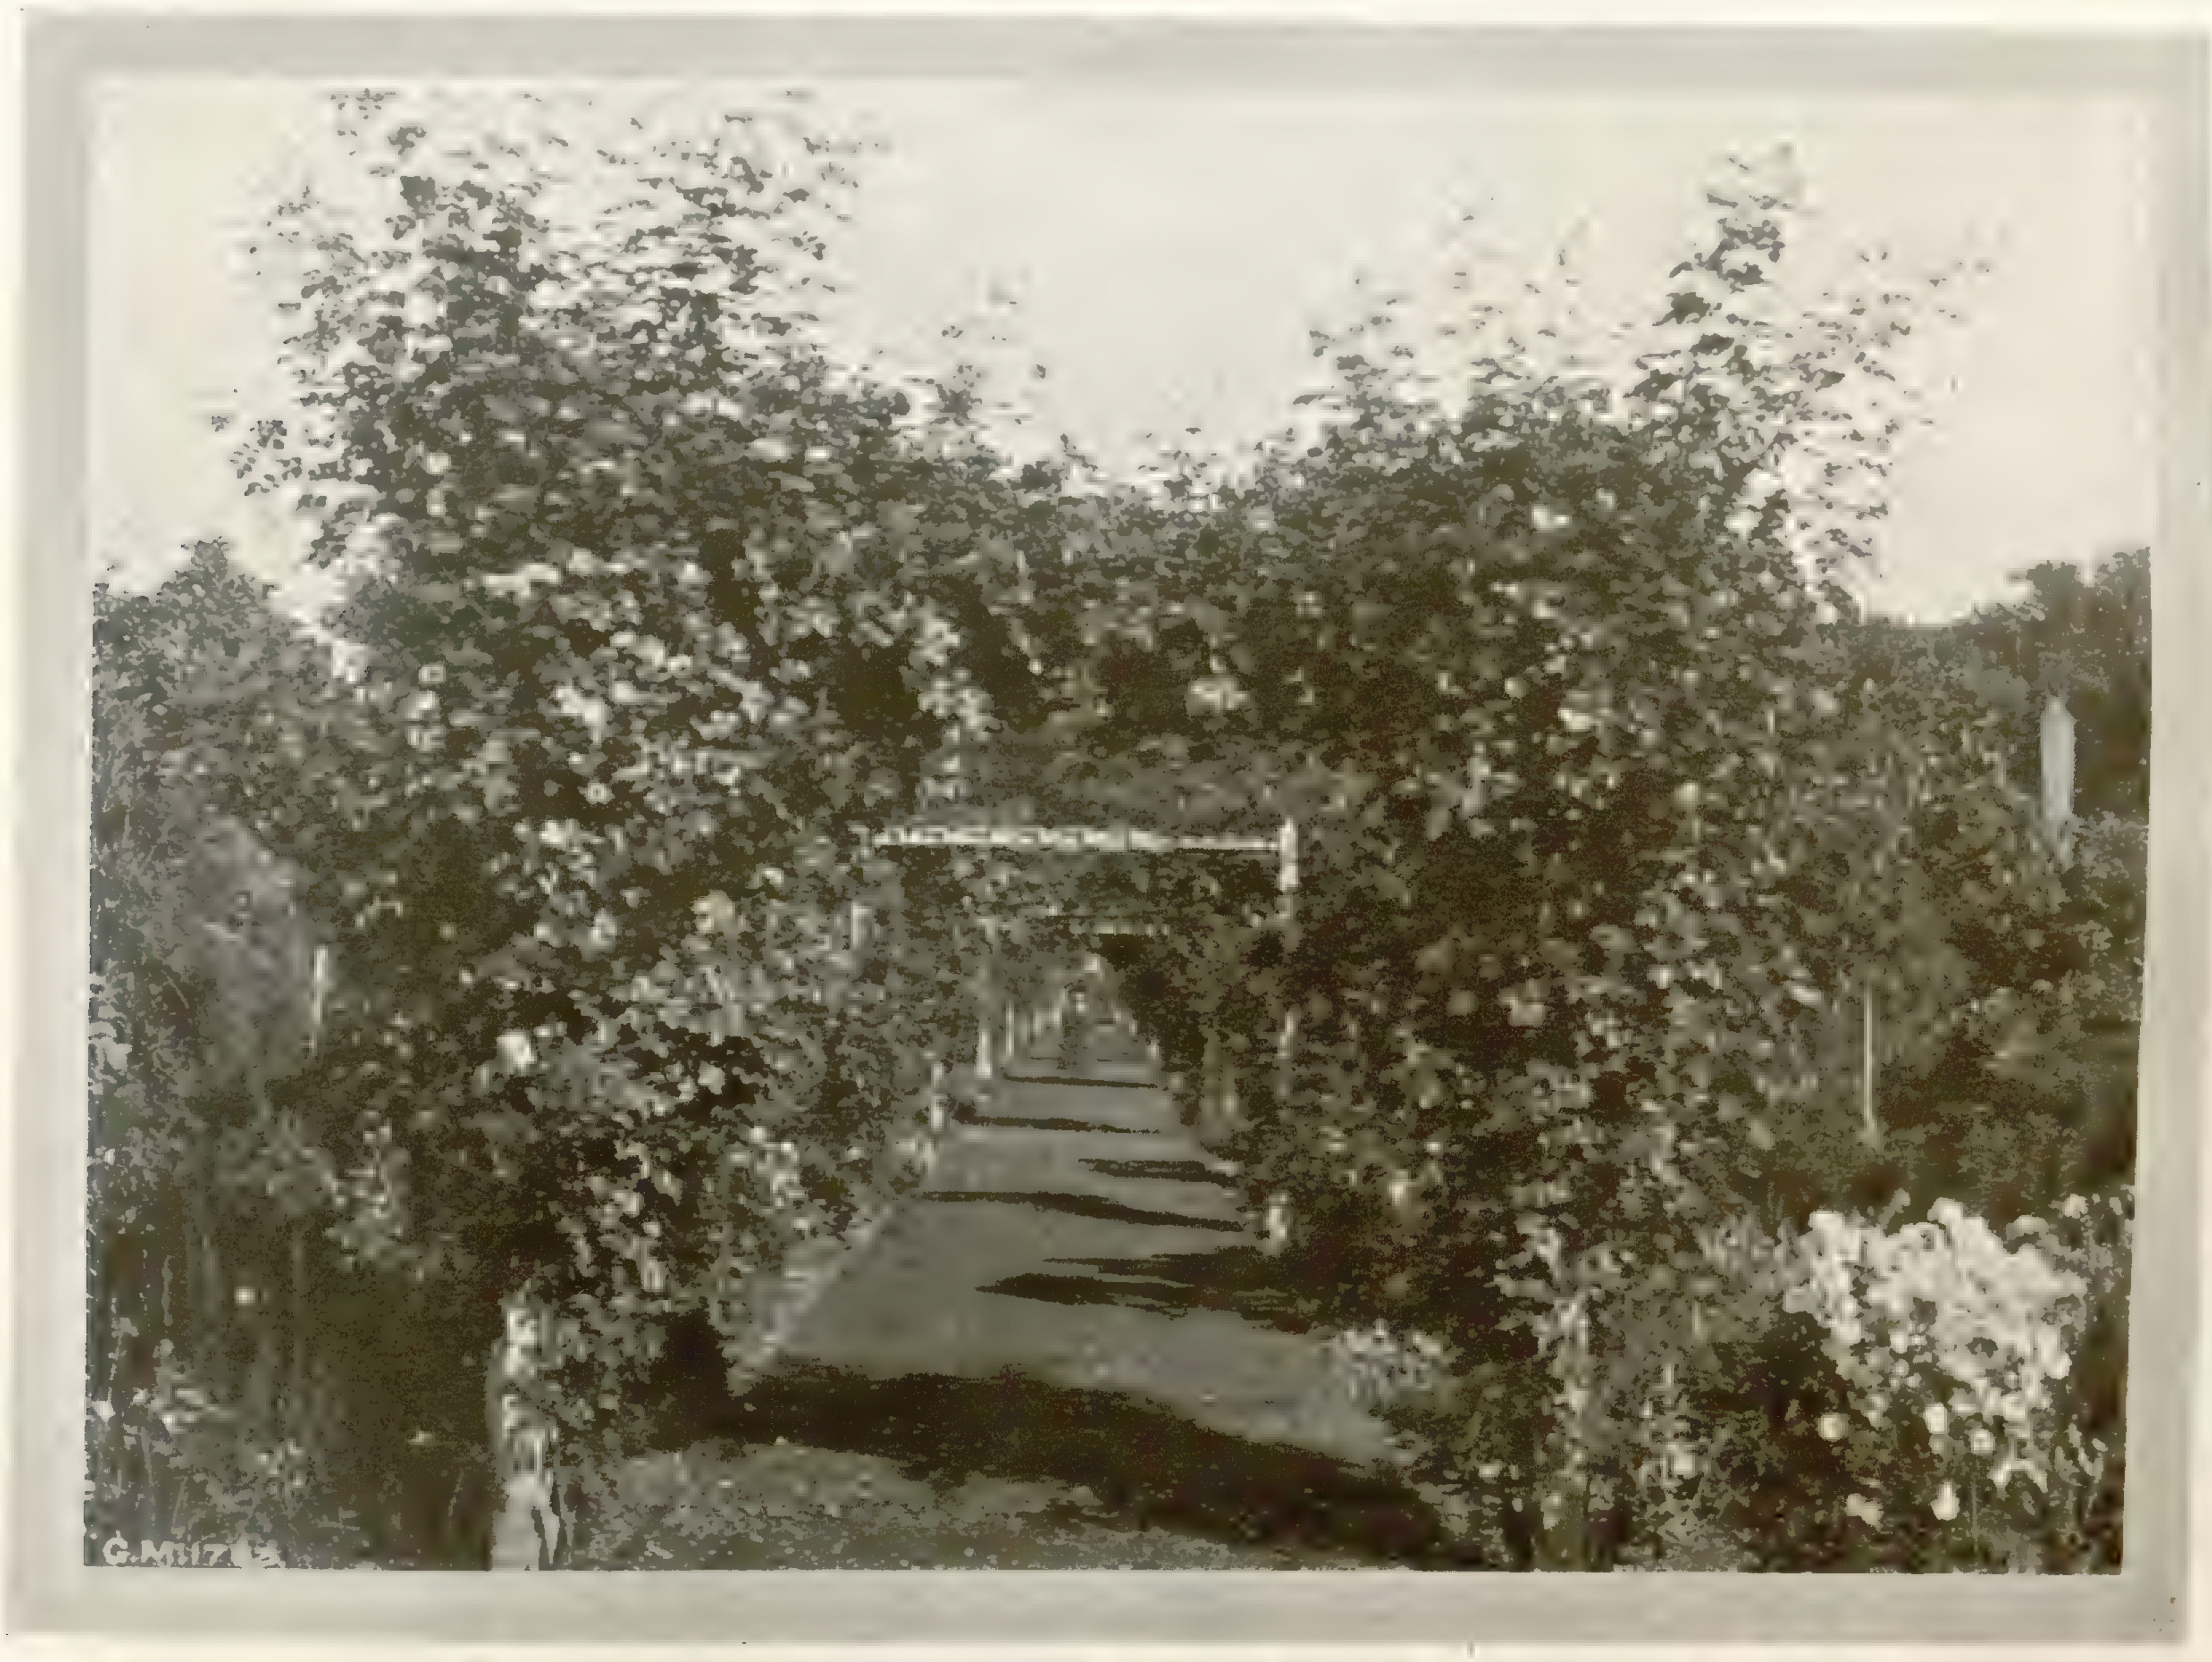
Messrs. J. Cheal and Son, Crawley, put up a very attractive exhibit of finely-coloured apples. Mr. D. Russell, Messrs. J. Peed and Son, Norwood, and Messrs. H. Cannell and Sons, Swanley, Kent, all showed apples and pears largely, the latter firm presenting a particularly attractive collection of bright and finely-grown fruits.

Messrs. W. Wells and Co., Merstham, put up a fine bank of chrysanthemums, a sort of ideal conservatory arrangement as in the great majority of cases the flowers were on the plants. Single, decorative, incurved, and Japanese varieties were almost equally represented, the latter occupying the post of honour. Along the background were big flowers of Mrs. F. C. Stoop, Miss Lilian Hall, White Queen, Mrs. W. Hookey, Mrs. R. H. Witty, David Ingamells, Marie Loomes, etc. Singles were finely grouped in the front centre, while small decorative sorts were used in flanking groups. Two especially fine examples of Phœnix Roebelini occupied points of vantage, and ferns formed an edging; the addition of some bright autumn-tinted foliage would have made this group practically perfect.

(Continued on page 826.)

ROSE PERGOLA AT PRESTON HALL.

The pergola as a means of displaying to the best advantage the distinctive charms of roses of rambling habit continues to enjoy a high degree of popularity, and in many gardens may be seen pergolas in course of construction, preparatory to an extension of the culture of Wichuraiana, polyantha, Ayrshire, and other roses that require support. Pergolas have many advantages as aids in the enhancement of the attractiveness and interest of the garden, and because of this it is satisfactory to know that they are regarded with much favour by those who appreciate the graceful growth and the beauty of flowers or foliage of climbing plants. One of their chief advantages is the facility with which they can be adapted to the area in which it is intended they should be a conspicuous feature, and to the amount available for erecting and furnishing them. It matters not whether pergolas be of large size and ornate in design, or of quite modest dimensions and characterised by simplicity, provided and this is an important point—they are more or less in agreement with their environment. Another advantage is they afford ample opportunity for the display of a considerable diversity of taste on the part of the owner, and as the result of this we see in visiting gardens a much greater difference in design than in the case of some other garden features. It matters not whether the supports be of brick or stone, of square cut timber or of roughly trimmed oak posts or larch poles, provided appropriateness has received due consideration in the preparation of the design.



A FINELY FURNISHED ROSE PERGOLA WITH GRASS WALK AT PRESTON HALL, DALKEITH.

Whether the pathway be of gravel, flagstones, or turf is very much a matter of individual taste, provided the structure and the pathway is in agreement. Pergolas with brick or stone pillars should, as a rule, have pathways of flagstones or gravel; but for those with a framework of wood the paths may be of grass or either of the two materials mentioned, provided the woodwork is not so constructed as to exclude, when covered with the growth of roses or other climbers, the light and air from the grass, and thus prevent it making a satisfactory growth. A springy, closely cropped turf makes the most pleasant of all paths during the summer months, but without a sufficiency of light and air, the grass will become thin and drawn, and anything but satisfactory. It should also be mentioned that grass walks are not suitable for pergolas through which there is much traffic irrespective of the weather. On the other hand, where the pergola is intended chiefly as a resort during the summer months when the roses are yielding of their wealth of bloom and the supports are a goodly distance apart, grass forms an ideal walk. We have conclusive evidence of this in the rose pergola that forms so attractive a feature of the kitchen garden at Preston Hall, Dalkeith, the residence of Mrs. Callender. This pergola, as so well shown, is of great length, and the uprights and cross far enough apart to allow the light and air essential to the health of the grass to reach the pathway.

This pergola has the further advantage of being of sufficient height and width to allow two or three persons to walk abreast without inconvenience to themselves or injury to their clothing. This is an important point, and one to which attention has been directed in these pages on several occasions. There is still room for improvement in this detail, and as an incentive to this being effected with as little delay as possible, we again direct attention to the fact that few things are more annoying when walking along a pergola than to have to dodge the growths of the roses, or in the case of ladies to have hats or other articles of apparel disarranged, or it may be damaged. As Mrs. Callender fully appreciates the beauty of climbing roses, all sections are well represented in the delightful gardens of Preston Hall, and the pergola is furnished with varieties that occupy a high position in the respective sections to which they belong. G.

AMELANCHIER CANADENSIS.

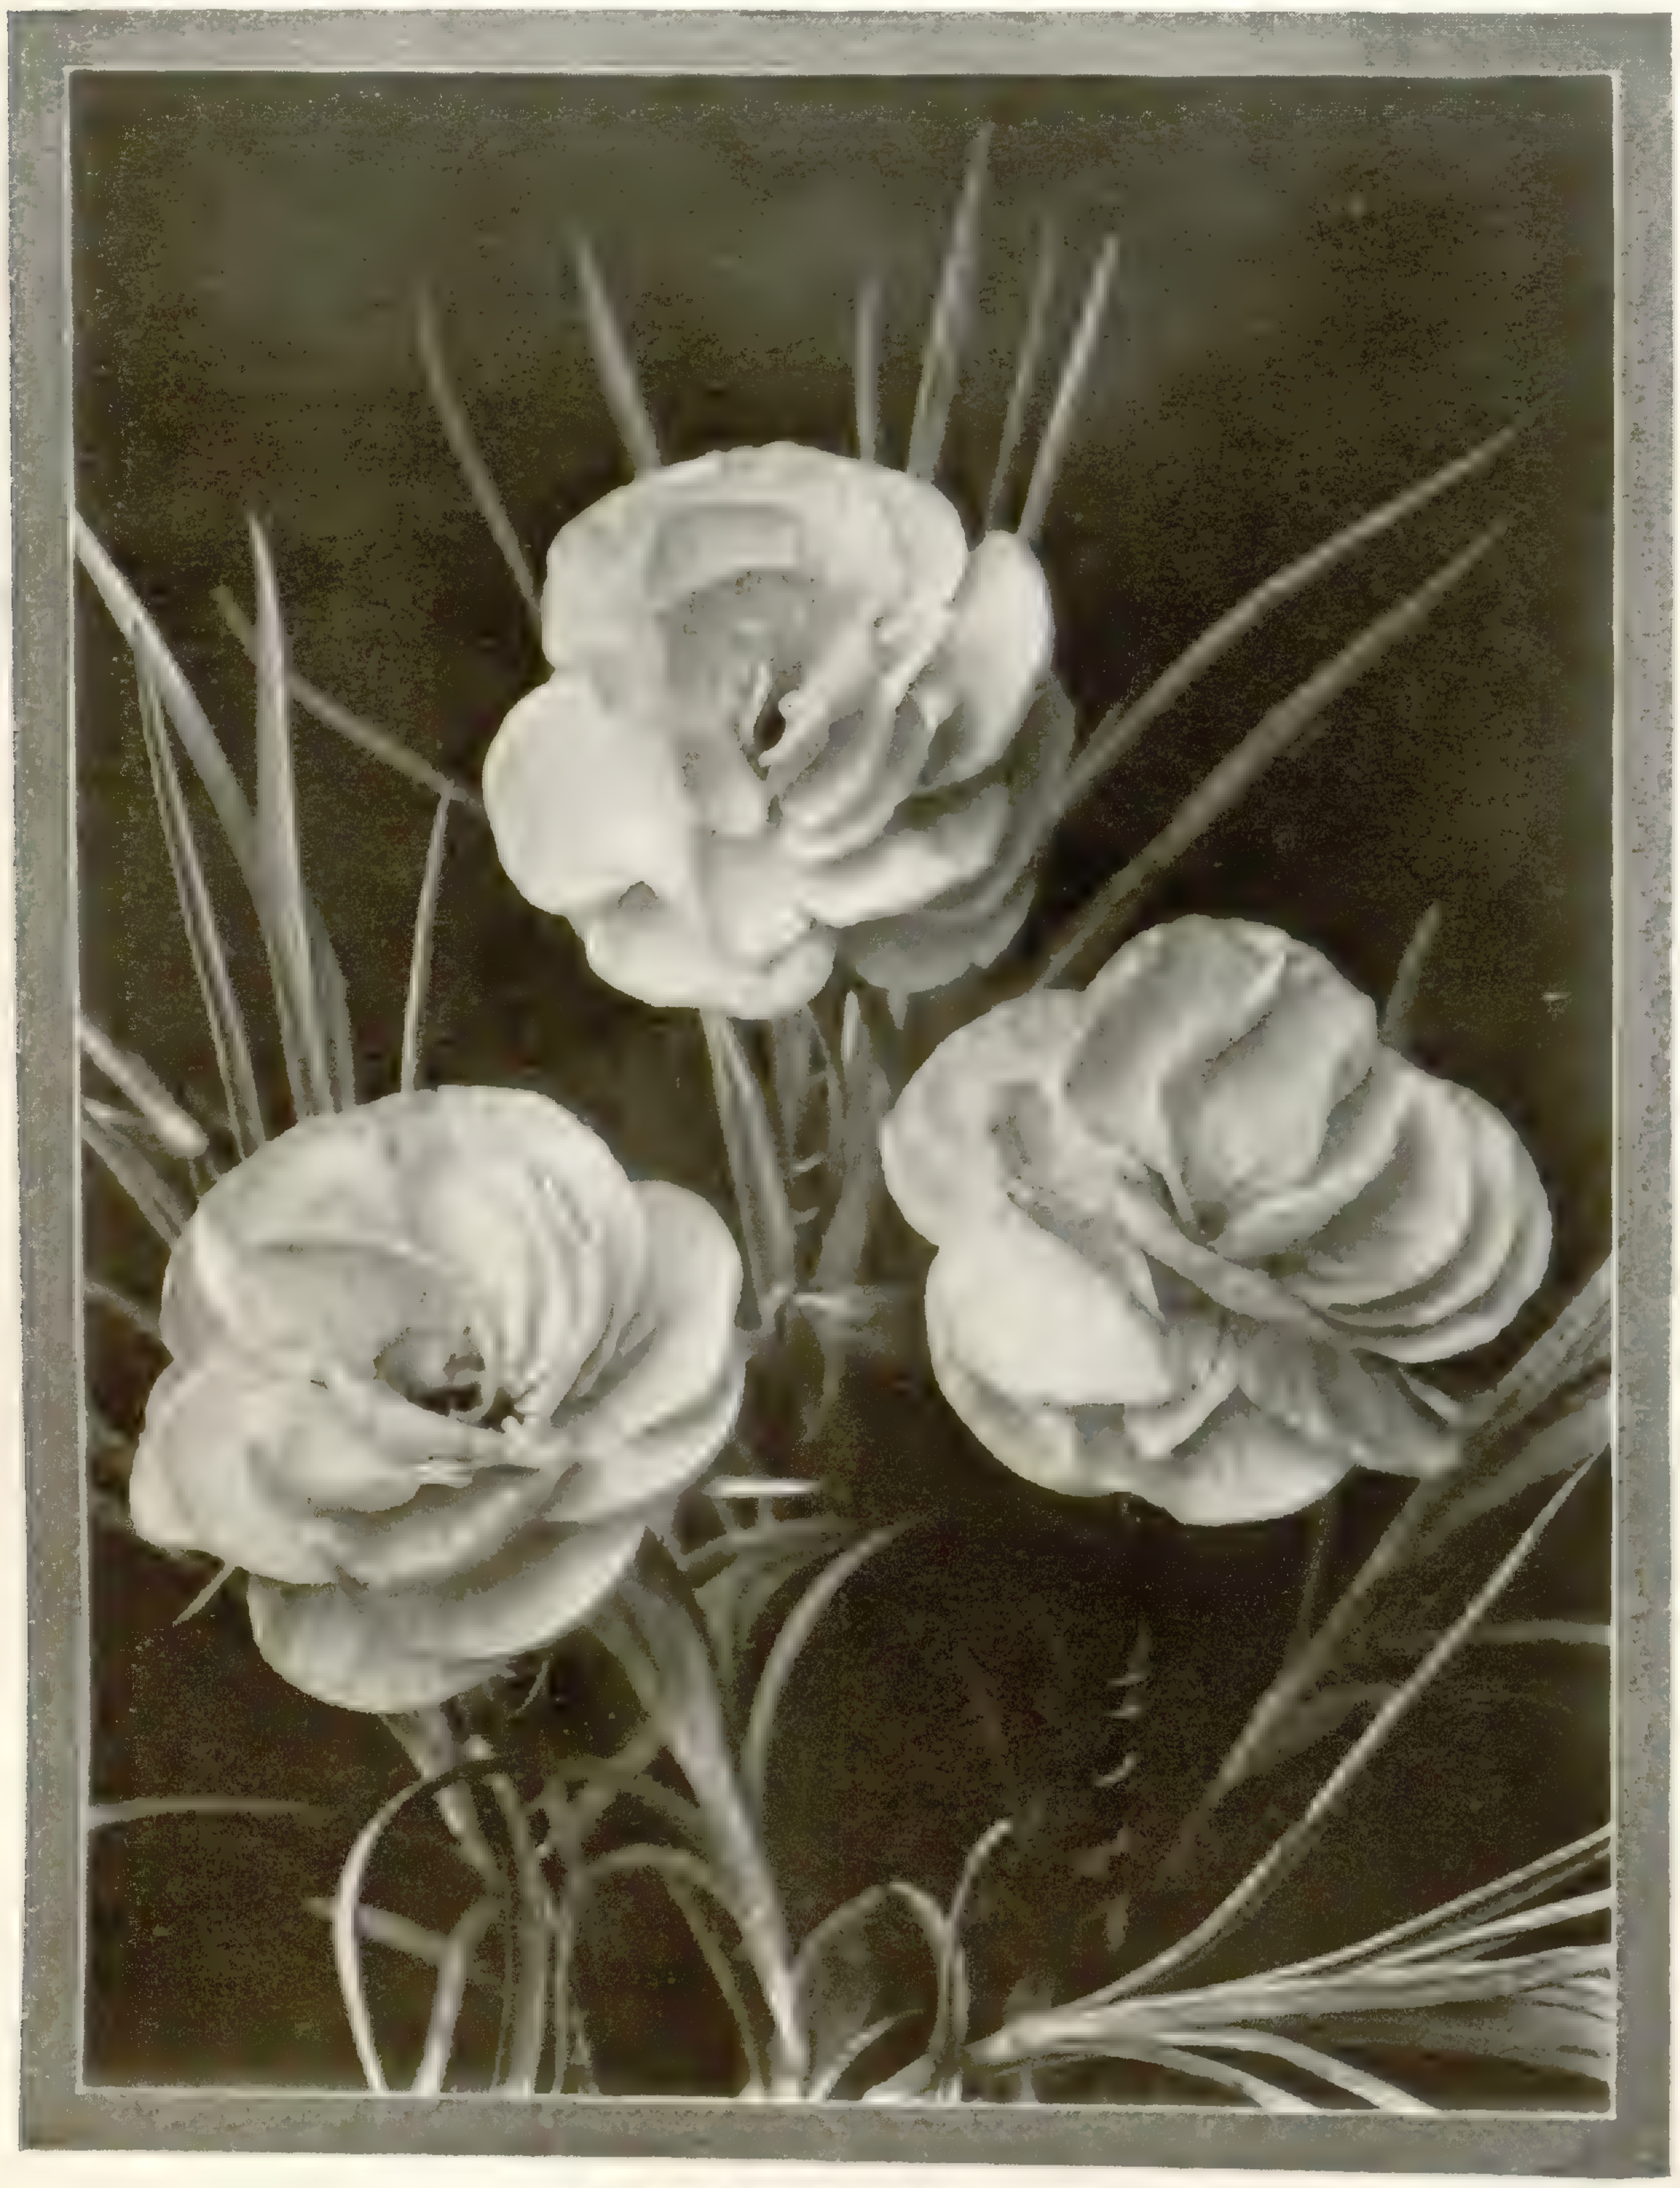
The virtues of this trees as a showy flowering subject in May have often been extolled, but less frequently has attention been directed to its decorative qualities in autumn, yet, if anything, its effectiveness is most pronounced at the later season, for at that time the leaves are bright red, or sometimes red and orange. Furthermore, the effect is more lasting in autumn, for the colour is maintained over a period of from two to four weeks, while in spring the white flowers are rather fugitive, and a heavy rainstorm soon after they expand may seriously injure the blossoms. A. canadensis has the advantage of being a good-natured and easily-grown tree, and there are few gardens where it will not succeed. Soil is not an important factor towards success, for it thrives alike in light, medium, and heavy loam. In the warmer kinds of soil, however, the leaf colour in autumn is most pronounced, while trees growing in open positions are usually more effective than those growing in shade. A great variation is noticed in habit, leafage, and flowers of this tree, and it is possible that too wide a system of grouping has been adopted. It would possibly have been better to include some of the forms as good varieties which are at present ranked as synonyms. W. D.

NEW CHINESE TREES AND SHRUBS.

The current issue of the Kew Bulletin contains several important contributions relating to trees and shrubs, and is therefore of much interest to those who appreciate their importance in the garden. We make the following extract from Mr. Bean's notes on new trees and shrubs that have been introduced from China.

Berberis verruculosa, Hemsley and Wilson.

Among the numerous species and forms of berberis which recent exploration in China has added to our collections, none is more distinct and in habit at least more pleasing than this. It is an evergreen bush of low, sturdy, very neat habit, probably never much more than two feet high. One of the most distinctive characters of the plant is the roughness of the young stems, due to a dense covering of small dark warty excrescences. Leaves densely arranged in fascicles along the branch, elliptic-oblong, ½ to 1½ inches long; spine-tipped and spiny-toothed, coriaceous, dark shining green above, glaucous beneath, margins revolute. Flowers golden-yellow, short-stalked, solitary or in few-flowered fascicles. Fruit black covered with a blue bloom. The species was discovered in Western China and introduced by Wilson in 1904. Four years later it flowered with Messrs. Veitch at Coombe Wood, and to them Kew is indebted for a healthy plant lately added to the collection.



CARNATION CAMBRIA.

A beautiful self carnation with canary-yellow flowers. Raised by the Rev. C. A. Gottwaltz, and introduced by Messrs. A. R. Brown, Lim.

Carpinus polyneura, Franchet.

This beautiful hornbeam is only represented in cultivation by a single tree at Kew, growing at the north entrance of the Rhododendron Dell, and now about 16 feet high. It was raised from seed sent by Mr. A. Henry, in 1889, from Central China. It is a small tree 30 feet high, with slender branches, pendulous at the ends, which give the tree a very elegant aspect. Leaves ovate, acute, slightly cordate at the base, 1 to 2½ inches long, ½ to 1 inch wide, sharply (occasionally doubly) dentate, dark shining green and glabrescent above, and with silky down on the midrib and veins beneath. The leaves differ from those of other hornbeams in cultivation in being flat and scarcely plicate. In its leafless state the tree is distinguished by the narrow, linear, silky stipules which persist through the winter and until the appearance of the new leaves. The tree at Kew flowers regularly, and has borne clusters of fruit, but the seed formed has hitherto been infertile.

Corylus Colurna var. chinensis, Burkill.

Few deciduous trees are more handsome in leaf and habit, or more interesting in fruit, than the "Constantinople Nut"—Corylus Colurna. It reaches 70 to 80 feet high in continental gardens, and is the only species of Corylus hitherto in cultivation which makes a genuine tree. A new arborescent variety, however, has recently been introduced from Central China, viz., the var. chinensis of Burkill. Originally discovered by Henry, in Szechuan, in 1888, nuts were first sent home by Wilson in 1901, from which a number of young trees were raised by Messrs. Veitch at Coombe Wood, and thence obtained for Kew. Mr. Wilson informs me that this tree is usually met with 50 to 60 feet high, but that he has seen it over 100 feet high—a magnificent size for one of the hazels. The leaves are ovate-oblong or obovate, as much as 6½ inches long by 4 inches wide, deeply and obliquely cordate at the base, acuminate, rather finely and unequally dentate; pilose on the midrib, and with scattered bristles above; glandular-pubescent on the midrib and veins beneath. The young branchlets and petioles are also glandular-pubescent. Our young plants have not borne flowers as yet, but they give promise of being quick growers and perfectly hardy.

Fokienia Hodginsi, Henry and Thomas.

Mr. H. Clinton Baker, of Bayfordbury, has recently presented to Kew a plant of this new and extremely rare conifer. It is one of a few living specimens sent to him in 1909 by his brother, Captain L. Clinton Baker, R.N., from the Fokien province of Eastern China. The species has been made the type of a new genus of coniferæ by Henry and Thomas. It is described by the authors as in many respects intermediate between Cupressus and Libocedrus, the cones being similar to those of the cypresses belonging to the Chamaecyparis group, the foliage resembling in many points that of Libocedrus macrolepis. It is described as a tree 40 feet high. On Mr. Clinton Baker's plant—a young one about four feet high—the flattened, sharply pointed leaves are ¼ to ⅓ inch long, deep lustrous green above, with conspicuous white bands of stomata beneath. The leaves are in flattened whorls of four, the outer pair twice as large as the inner pair. Mr. Clinton Baker thinks that it will not withstand our winters, but, in any case, it will make a handsome evergreen for conservatories and winter gardens, and may prove suitable for the south-western counties in the open.

SELF CARNATION CAMBRIA.

There is a peculiar fascination about a yellow self carnation, varieties of this colour being the more highly esteemed by carnation lovers by reason of the fact that good flowers are by no means plentiful. The variety Cambria, of which an illustration is given herewith, is a flower of beautiful form and colour, and is likely to become a great favourite, especially among exhibitors. It was raised by the Rev. C. A. Gottwaltz, of Droitwich, to whom growers are indebted for a considerable number of excellent and well-known carnations. Messrs. A. R. Brown, Lim., Kings Norton, hold the stock, and include it in their list of novelties for the season. Our illustration is a reproduction of a photograph of blooms that were exhibited by Messrs. Brown in one of their winning stands at the Midland Exhibition of the National Carnation Society, and it shows the fine breadth of petal and beautiful outline of the flower. It is therefore not necessary to say more than mention that the colour is a clear and pleasing shade of canary-yellow. When exhibited at Birmingham the enthusiasts commented very favourably on the merits of this fine variety, and we have every confidence in commending Cambria to the attention of those of our readers who cultivate carnations, whether for the border or exhibition.

Advice given on all matters appertaining to **LANDSCAPE GARDENING.**

GEO. JACKMAN & SON,
Woking Nurseries, Surrey.
Established over a Century. (Nurseries 200 acres.)

GARDENING FOR HOUSE ADORNMENT.

The love of flowers in the garden leads infallibly to the desire for floral beauty in the house; there are persons who object to plucked blossoms, yet even they rejoice to see growing plants in the rooms and corridors, and especially upon the dinner table. The gardener, therefore, whether professional or amateur, is always confronted with the problem how best to bring his art to bear upon the adornment of the home.

Perhaps the simpler the plan the more gratifying the results. One exceedingly easy and novel scheme is the making of a primrose ball to hang in some window, or a series to suspend along a conservatory adjoining the drawing-room. The best foundation is a small piece of the fish netting that is used to protect fruit trees; this is heaped up a few inches with the most tussocky bits of turf-loam, with perhaps some cocoanut-fibre refuse also, and a third portion of old leaf soil, which so conduces to the welfare of the primrose; the corners of the netting are then gathered together and tied firmly, enclosing the soil materials. A rounded shape is to be aimed at. The next process is to plant young primroses, through the mesh of the netting, all over the ball, pressing leaf-mould firmly around their roots. After this is done more cocoanut-fibre refuse is bound on between the little plants, fine green wool being the right material to use. Finally, dried moss is similarly used to hide the cocoanut-fibre refuse. If the spherical shape has been kept the effect will already be good.

Spiræa japonica clumps can be taken up from the borders, the roots bound into a globe, and a mixture of equal portions of fibre and leaf-mould pressed solidly between all their inner spaces and added as a bound-on covering five or six inches deep, wool being used for the binding, and the coverings of cocoanut-fibre refuse and moss given as before. As the spiræa will only produce leaf and blossom from the top, however, a prettier effect is gained by inserting small roots of variegated arabis at intervals all over the base and sides.

The method of watering a ball of growing plants is to immerse it for a few moments in a pail of tepid water, hang it up to dry where the drip can do no harm, then return it to the position it adorns. Many other hardy plants can be used in this style: Creeping Jenny has a charming appearance, so has London pride, while miniature balls prove popular made of sedums or mossy saxifrages. It is generally wise to employ some jadoo, or else rely altogether upon the fertilised fibre sold for growing bulbs in. Large-rooting plants do not need the netting foundation.

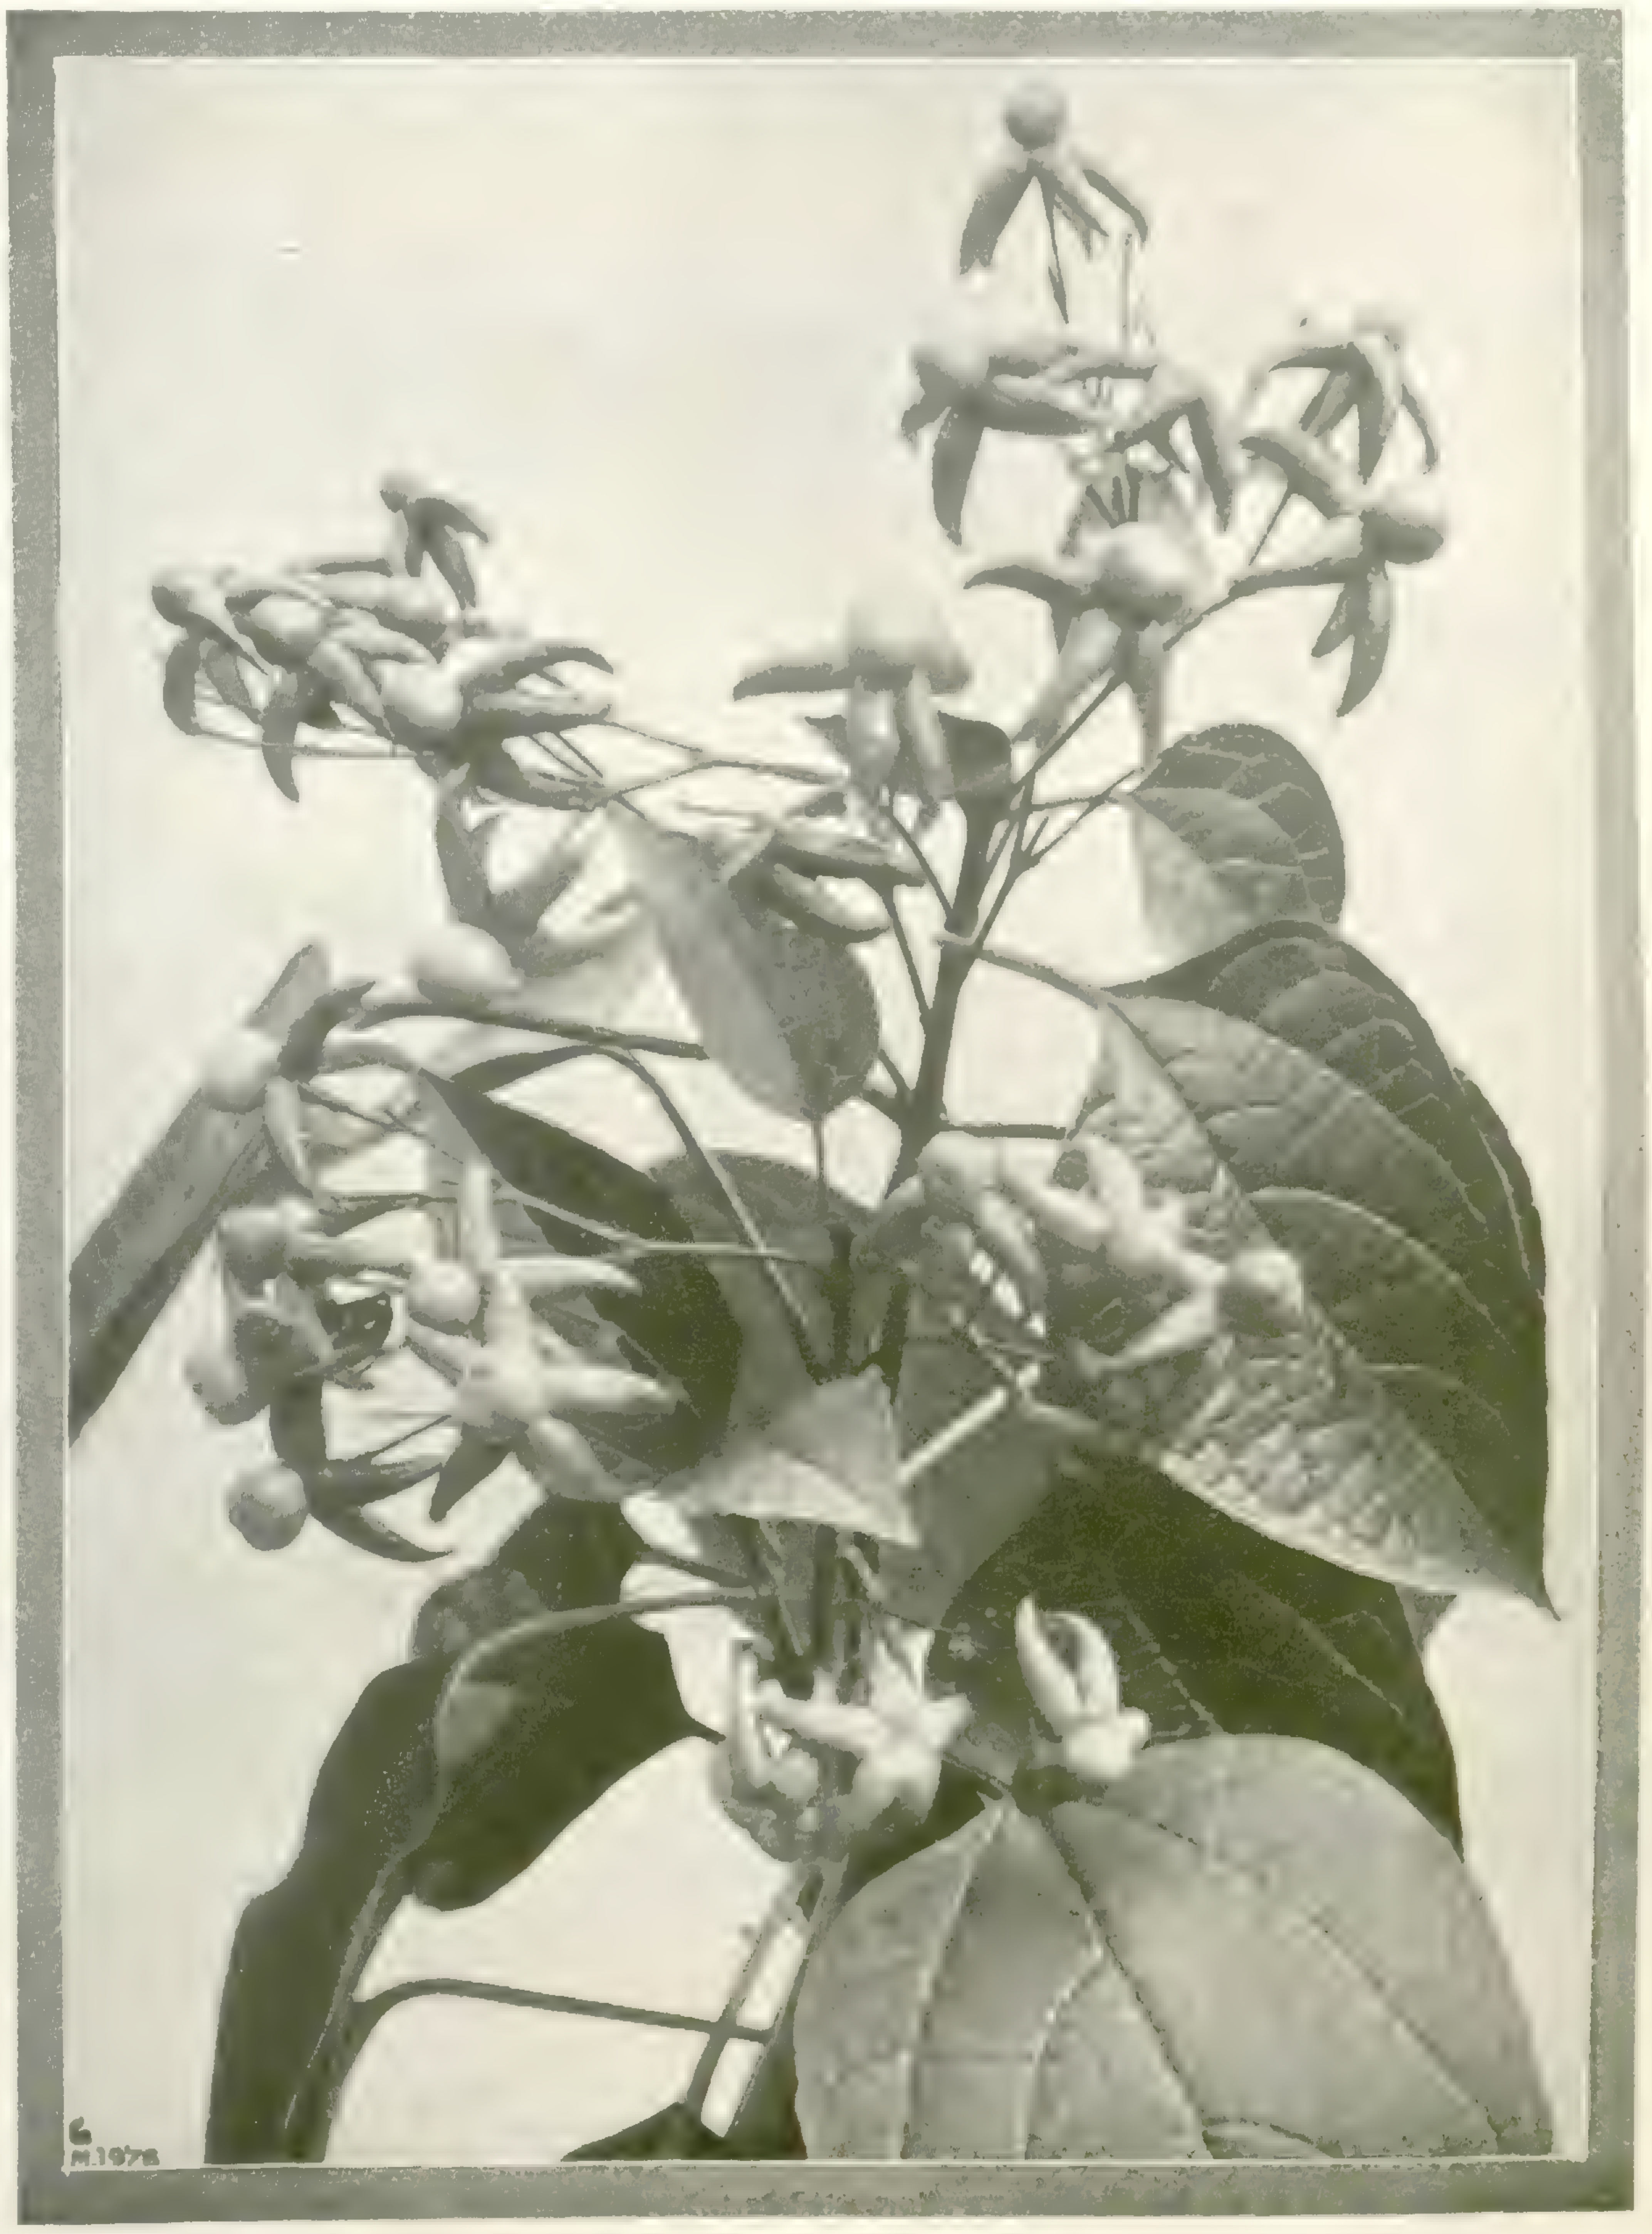
Flowering shrubs are a real joy indoors; they must be grown on in pots in cold frames or unheated greenhouses first, or else sunk in deep beds of ashes out of doors in a sheltered spot. Unless the pots are covered altogether, and a mulch of ashes or cocoanut-fibre refuse is thickly laid over the soil, the roots will be frozen. A beautiful early bloomer to choose is Daphne Mezereum; when it is opening its clustered rosy flowers all along the branches in February, it will be indeed welcome as a centrepiece for the dining table, or a pillar ornament in the hall, and every bud will come to perfection indoors, giving forth unrivalled perfume. There is also Daphne laureola, that is fragrant too, but has only greenish-yellow bloom.

Then the popular yellow winter jasmine is a plant of which the gardener should make many uses; it thrives in pots, will blossom indoors for weeks together without losing its healthy appearance, and can have variegated arabis, the silvery Sedum album, or yellow winter aconite bulbs planted above its roots.

Plant groups are often needed to beautify houses on festive occasions, such as dances, weddings, and dinner parties; the garden cannot supply these plants, but a moderately warmed greenhouse can always contain enough of them if suitable varieties and species are chosen. During the worst months of winter the many kinds of scented-leaved pelargoniums keep vivid green in a temperature of 50 degrees. Primula obconica, lilac, purple, and rose, should be in bloom, also Oxalis rosea and blue trailing lobelia. Seedling fuchsias can be kept from flowering by giving them increased pot room, until their blossom is trebly desirable in December, while freesias, Van Thol tulips, polyanthus narcissi, Roman and other hyacinths, Allium neapolitanum, and daffodils soon come into beauty.

A large collection of small palms, aspidistras, and the common hart's-tongue fern is of inestimable service in group forming. Several evergreen shrubs will thrive in the greenhouse, and serve to assist in house decoration, notably the gold and silver variegated euonymus, laurustinus, and myrtle.

Pots of single French anemones give bright bits of colour; these should be grown altogether in frames until buds are forming, when the greenhouse temperature will hasten them; Spanish iris are perfect room plants at a later season. Clumps of Dicentra spectabilis can be dug up and potted, even when new leaves are forming, and in a warmer temperature soon develop into beauty.



CLERODENDRON FARGESI.

An attractive hardy shrub that has whitish flowers in summer, followed by peacock-blue berries set in a purple calyx. A.M., R.H.S., October 24. The Director, Royal Gardens, Kew

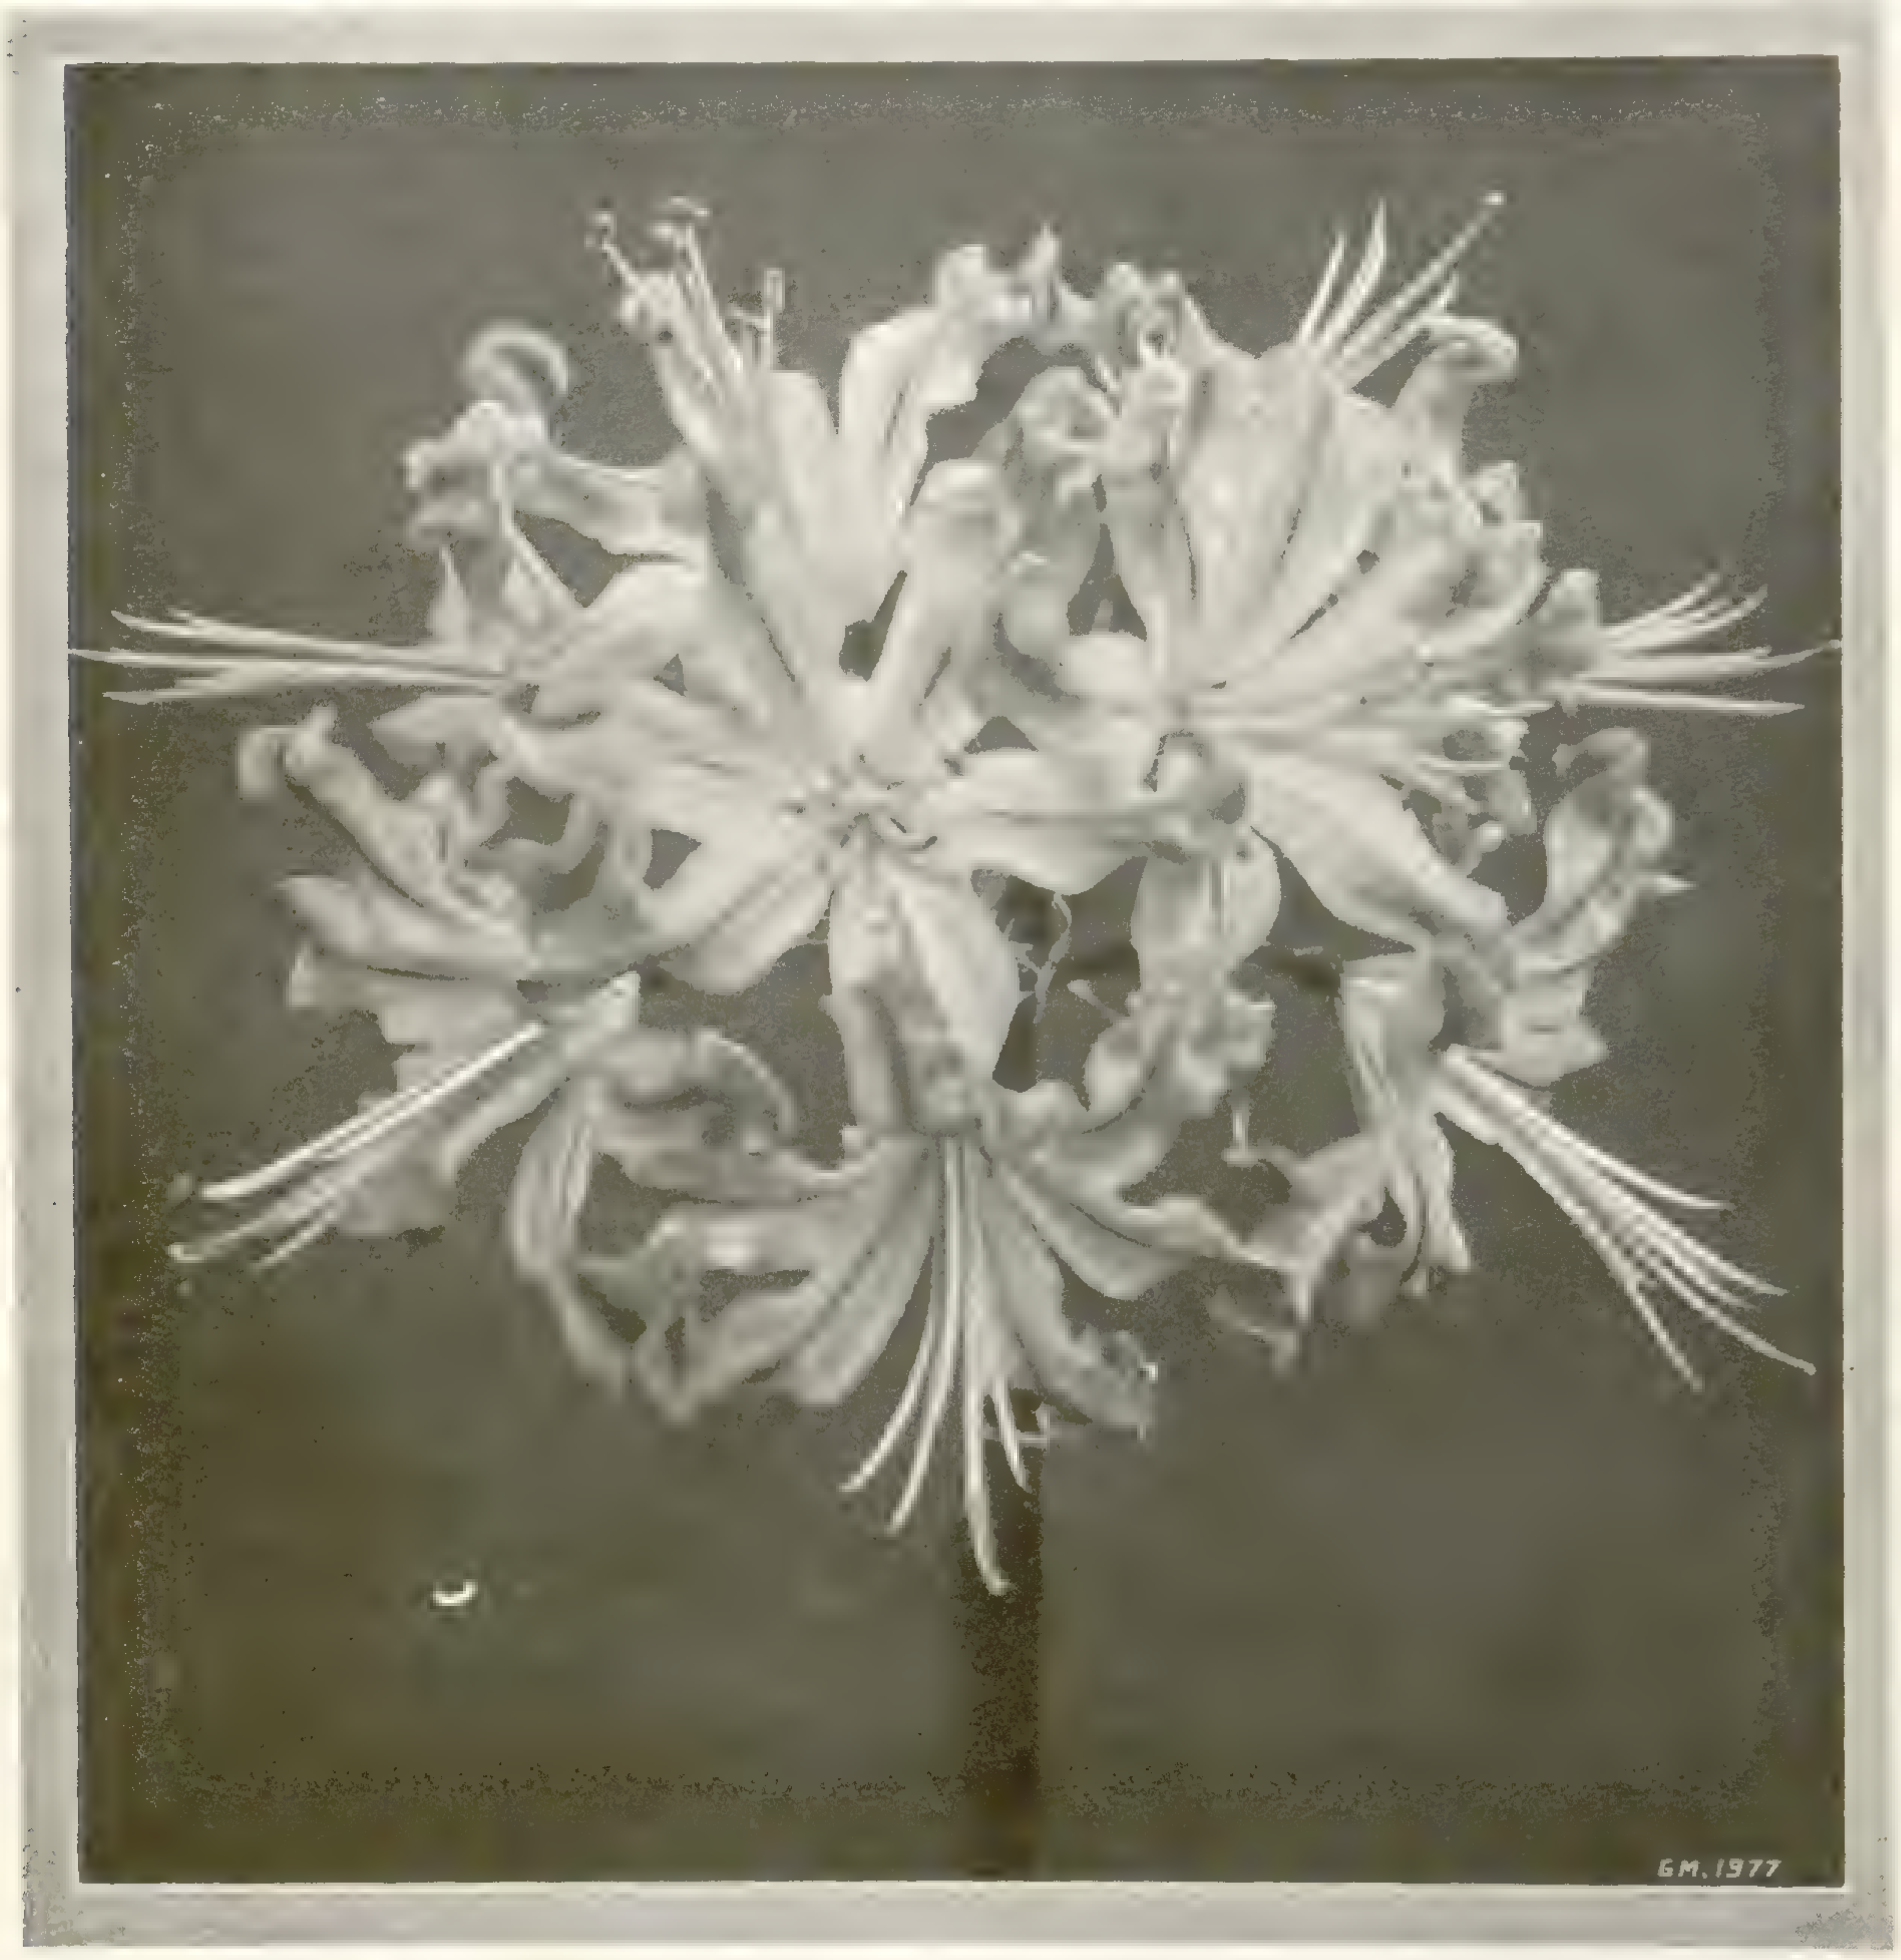
Wire hanging baskets, lined with moss, form receptacles for pot plants of small size, and when slung up in a hall add much to the charm of the home entrance.

M. H.

Carnation Scarlet Glow.—I like this carnation very much, the colour being so remarkably fine, and the shape perfect, added to which the stem is long and stout. It is, by your correspondent, Mr. Montague Allwood, regarded as the best scarlet, and I do not think that many will be found to differ from him.—W. T.

ROSE NOTES.

As I write we are having some heavy, but none the less welcome rains. It is just such weather as this which renders necessary some way of keeping superfluous wet from the roots of pot roses, and hence the advantage of a pit or frame. Recently I saw a simple and effective contrivance that answered the purpose admirably, and yet allowed of prolonged exposure to the benefits of the open air. Some sheets of galvanised iron roofing were laid upon a skeleton frame. They were easily put on or off, and were fixed against wind by some baulks of wood laid on top of them. Here we have just the thing wanted; full exposure without heavy rain and closeness, neither of which are wanted until later, when we can give the water as needed. This is a much better plan than laying the pots on their sides during excessive wet, and anyone can rig up such a shelter.



NERINE MRS. F. R. BALFOUR.

This fine new nerine has shapely, bright pink flowers, shaded with red at the tips of the segments. A.M., R.H.S., October 24. H. J. Elwes, Esq., F.R.S. (gardener, Mr. W. Walters), Colesbourne, Cheltenham.

Some dwarf roses that had to be lifted early were found to be growing nicely upon their own roots. We find those upon the manetti stock push out very freely when the soil is drawn around them, but this is not so frequent with the seedling and cutting brier, especially this season. That there is great help in this "own rooting," few would dispute, and I am much in favour of earthing up dwarfs with suitable compost to encourage those roots as well as those from the stock.

In most cases the ground is now in good condition for planting, and I would get this done as soon as possible, even to the sacrifice of a few tips of growth that are still very active on account of the mild weather and warm rains, feeling it would be better to have the roots in and settled under such ideal conditions. Trim off some of the leaves and soft growths before planting, as this will relieve the strain upon the roots, and prevent shrivelling. I cannot call to mind any year when we had more roses in bloom at the end of October. The flowers will last almost throughout November, if we escape any but slight frosts. With the more general use of a later growing stock in the brier, and also the increase of late-flowering teas and their hybrids, we obtain a much better autumn crop of flowers than was the case two or three decades ago. Then we had no later and better bloomers than Souvenir de la Malmaison, and a few of the tea-scented and noisette varieties in favourable positions.

The great advantage of putting in cuttings of either roses or stocks early in the autumn is already proved this season, for, on lifting two or three I found a promising ball of callus already formed, and in one instance even roots were in evidence. If a cutting will advance so favourably, does it not point all the more strongly to the advantage of early planting whenever the conditions will allow?

I would lose no time in making up cuttings of the brier and manetti, also of the Wichuraianas and other growers of sufficient freedom to be useful and able to support themselves without the aid of foster roots. Nor should we delay in the collection and planting of briers for standards. To get the ground well set about the roots of these is a great point towards successful rooting, and standard stocks are terribly punished by drying winds, in comparison with the dwarfs, which are almost completely buried, and thus quite free from the evils of drying.

It is encouraging to note how well the buds inserted during the past trying summer have "taken." We have very few misses, either upon standards or dwarfs; which is all the more gratifying because it was frequently necessary to water the stocks during the process of budding to obtain enough sap for the bark to lift easily. I think they are more promising than during rainy seasons when the bark has lifted exceptionally well. In the latter case, the stocks are apt to overgrow the rose bud.

May I say that the Editorial note (page 770) in the Gardeners' Magazine Rose Number upon "Awards to New Roses" expresses my idea upon that question absolutely. A. P.

NOTES FROM KEW.

Odontadenia speciosa.

The first time I saw this odontadenia in flower was, I believe, in the Botanic Gardens at Birmingham, but it has not come under my notice in such fine condition as it is now in the Victoria Regia house at Kew. This magnificent stove climber is rarely met with in gardens, though it is a stock plant in many nurseries, where it is frequently known as Dipladenia Harrisi. It is a vigorous growing climber, whose long, flexible shoots are clothed with pointed ovate leaves, about 6in. in length and disposed in pairs. The flowers, which are borne in terminal clusters, pendulous from their weight, are funnel-shaped, fully 3in. across the expanded mouth, and in colour apricot-buff, with the interior of the throat orange-red. In order to induce this odontadenia to flower in a satisfactory manner it needs to be trained to a lofty structure maintained at a stove temperature, conditions that just prevail at Kew. It is a native of Trinidad, and was introduced in 1854.

Thunbergia grandiflora.

Under similar conditions to the preceding, this well-known Indian climber is flowering freely, its large porcelain-blue flowers being borne for some distance along the pendulous shoots. It is a plant of easy culture, and quickly covers a considerable space, but to ensure a display of blossoms full exposure to sunshine is necessary.

Begonias.

The important part that begonias play in the embellishment of our glass structures at this season is well shown in the intermediate portion of the T range, where, irrespective of the hybrids of B. socotrana, which are so universally grown for autumn flowering, there are many others in bloom. Among these may be mentioned the Brazilian Begonia Haageana, with dense clusters of larger white flowers, which are studded with reddish hairs. This begonia will flower more or less continuously throughout the year. A variety, of which there are some good examples at Kew, is B. Haageana Drosti. This is characterised by larger clusters, while the individual flowers also much exceed those of the type. Other kinds, consisting of original species and garden hybrids are B. fuchsioides, red; B. Schmidti, white, dense compact growth; B. Weltoniensis, a very pretty hybrid, with pink flowers; B. Digswelliana, red; B. acuminata, white; B. carminata, deep pink; and B. President Carnot, with very large heads of rosy-pink flowers.

Dædalacanthus Watti.

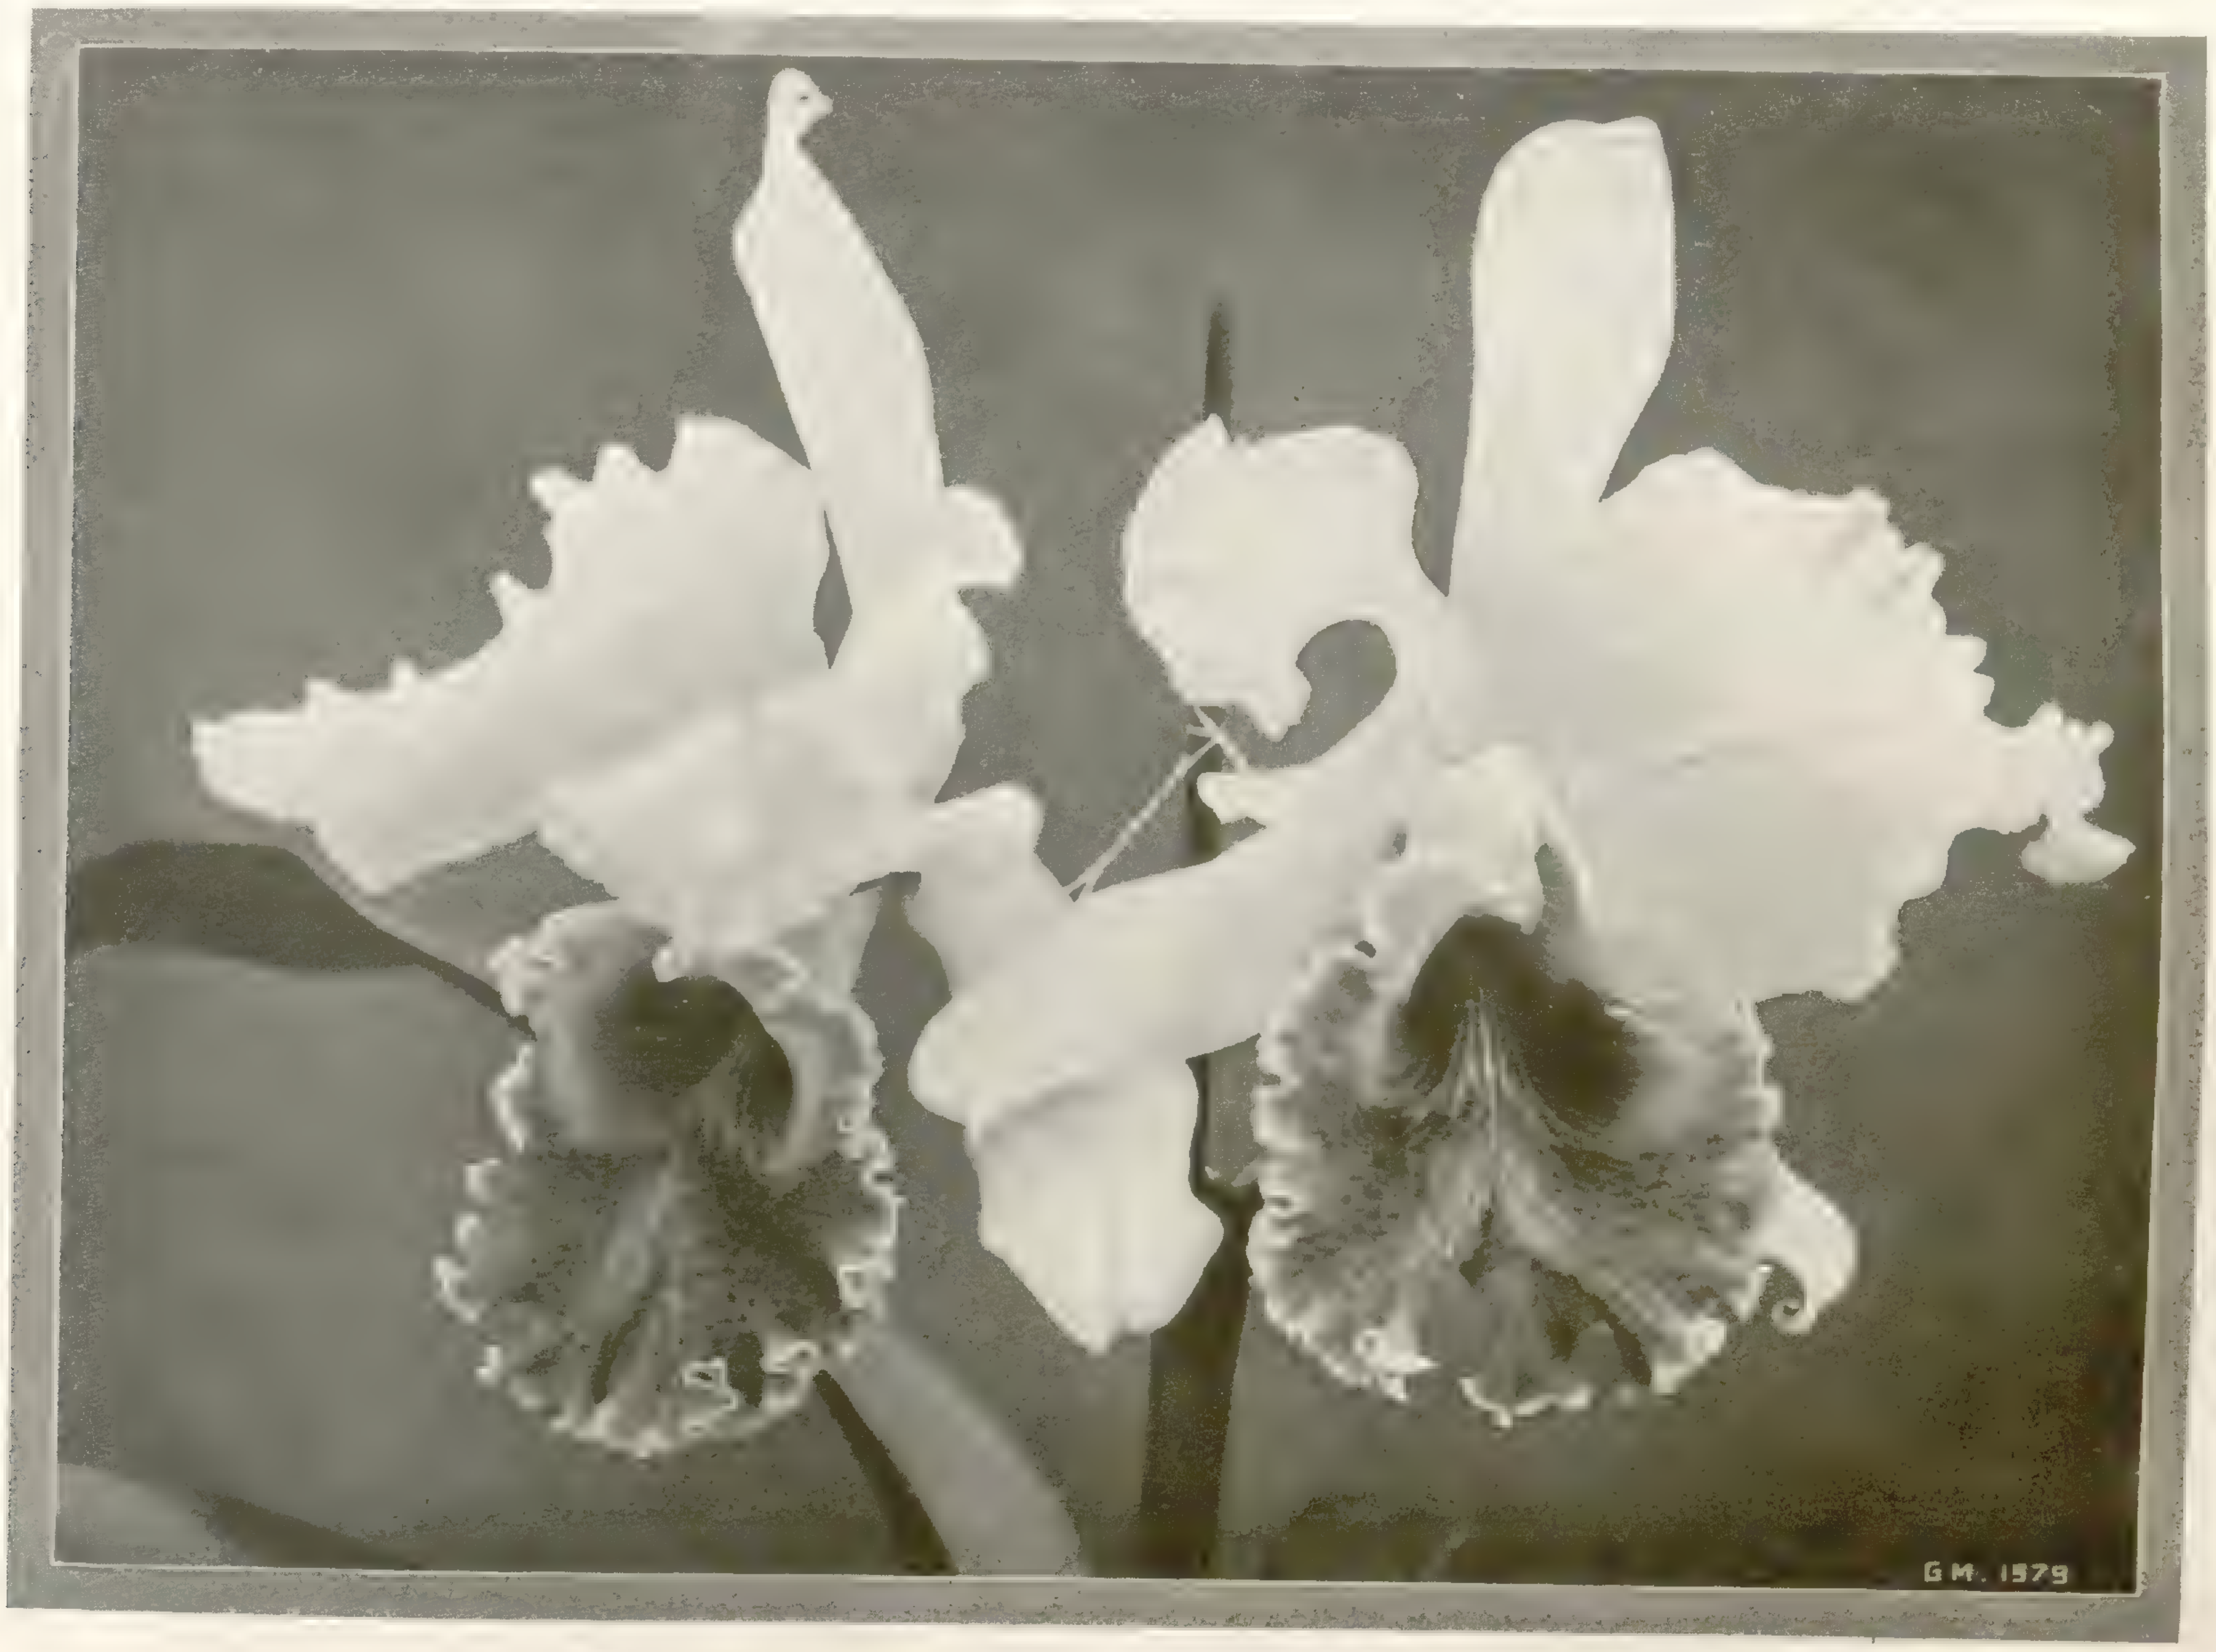
A well-known member of this genus is Dædalacanthus nervosus, whose steely-blue flowers are borne throughout the winter and well on in to the spring. D. Watti is nearly related to it, but differs therefrom in several well-marked features. In the first place, it blooms in the latter part of the summer and in autumn, while the blossoms are of an uncommon metallic purple tint. It is a native of Northern India, and was introduced about ten years ago. At first it was known as Dædalacanthus parvus, a decidedly inappropriate name, but which was changed to that of Watti. Its value for the decoration of the intermediate house at this season is well shown in the T range.

Aphelandra tetragona.

Many of the aphelandras will flower in a comparatively small state, but this, the oldest species of all, is seen at its best when from two to three feet in height. As in the other members of the genus the flowers are arranged in decussate terminal spikes, and are remarkably effective when at their best. It is of comparatvely easy culture, and is sometimes met with under the specific name of cristata. It is now in flower in the intermediate portion of the T range.

Achimenes coccinea.

Some suspended baskets of this little bright-flowered achimenes have for a long time been wonderfully effective in the cool portion of the T range. It is one of the oldest members of the genus, but is not so popular as many of those forms with larger blossoms. Why, it is difficult to say, for when at its best it is really charming. Like the other forms, it can be either grown in pots or in hanging baskets. K.



LÆLIO-CATTLEYA ST. GOTHARD McBEAN'S VARIETY.
A handsome hybrid with rosy-purple sepals and petals, and a rich crimson-purple lip, with yellow throat. F.C.C., R.H.S., October 24. Messrs. J. and A. McBean, Cooksbridge, Sussex.

NEW PLANTS, ETC.

◆

LÆLIO-CATTLEYA ST. GOTHARD, McBEAN'S VARIETY.

For fine size, excellent form and brilliant colouring, this splendid orchid would be difficult to beat. It suggests a magnificent Cattleya Hardyana, but with deeper purple colouring. The very broad and rounded lip is a striking feature, this being a rich and beautiful crimson-purple shade, with deep yellow throat. The parents are L.-c. Gottoiana and C. Hardyana. F.C.C., R.H.S., October 24. Messrs. J. and A. McBean, Cooksbridge, Sussex.

LÆLIO-CATTLEYA LUMINOSA AUREA.

In this handsome hybrid the yellow Walton Grange variety of Lælio tenebrosa was used as parent, in combination with Cattleya aurea. The flowers are large, and the light yellow sepals and petals droop a little, forming a fine background for the large deep velvety purple lip. F.C.C., R.H.S., October 24. Lieut.-Colonel Sir George Holford (grower, Mr. Alexander), Westonbirt, Tetbury, Gloucester.

VANDA KIMBALLIANA ALBA.

A charming albina form, the flowers being quite white save for a little light green-yellow shading on the lip. It is a distinct and beautiful acquisition. A.M., R.H.S., October 24. Messrs. Mansell and Hatcher, Rawdon, Leeds.

NERINES.

Mrs. F. R. Balfour.—A very distinct and particularly beautiful seedling, with a shapely truss, and rounded flowers with somewhat broadened segments. The latter are prettily waved at the margins, rich pink, with bright red shading at the tips. A.M., R.H.S., October 24. H. J. Elwes, Esq., F.R.S. (gardener, Mr. Walters), Colesbourne, Cheltenham.

Mrs. Meade-Waldo.—A fine strong growing variety, with bold flowers of a bright orange colour, tinted with scarlet. A.M., R.H.S., October 24. H. J. Elwes, Esq.

Snowflake.—Though not such a strong grower as some of the other seedlings submitted, this is very beautiful, being quite white, with broad, wavy segments. A.M., R.H.S., October 24. H. J. Elwes, Esq.

Hon. Miss Gibbs.—Another strong grower, bearing a large umbel of bright purplish-red flowers. A.M., R.H.S., October 24. H. J. Elwes, Esq.

LONICERA NITIDA.

At first sight this neat, shiny-leaved shrub seems to have a closer relationship to the cotoneasters than the honeysuckles. It is evergreen, and its small shining leaves are closely set on the twiggy branches. It is said to be quite hardy, and it should prove a capital shrub for the rock garden, and wherever small evergreens are needed. The greenish-white flowers are small and ineffective. A.M., R.H.S., October 24. Messrs. Jas. Veitch and Sons, Chelsea.

VERONICA SILVER QUEEN.

A dwarf, shrubby veronica, apparently of the Andersoni class, but with closely set leaves that are bright cream colour, with a medium green line. Should be useful for window boxes, and for edging groups of shrubs wherever it is found hardy. A.M., R.H.S., October 24. Messrs. Wm. Cutbush and Son, Highgate.

CLERODENDRON FARGESI.

Hitherto Clerodendron trichotomum and C. Bungei have been regarded as the only hardy members of a fairly popular genus, but to these must now be added C. Fargesi, a species that outranks the older sorts in beauty, though possibly not in stature. C. Fargesi forms a tall evergreen bush, and has an abundance of bright green oval leaves, each four or five inches long and about three inches broad. The flowers are terminal, whitish, and borne in summertime, and they are followed by attractive peacock-blue fruits, each set in a purplish fleshy calyx. A.M., R.H.S., October 24. The Director, Royal Gardens, Kew.

BERBERIS VERRUCULOSA.

A low-growing species from Western China. It is hardy, rising only about two feet high, and clothed with spiny evergreen shining green leaves. The yellow flowers are followed by purplish fruits. It is a dense growing shrub that may in time be useful for coverts as well as for ornamental planting. A.M., R.H.S., October 24. Messrs. Jas. Veitch and Sons, Chelsea.

CHRYSANTHEMUMS.

Bronze Goacher's Crimson.—A counterpart of the popular early-flowering Goacher's Crimson in every respect save colour, which is bright chestnut-bronze. A.M., R.H.S., October 24. Messrs. W. Wells and Co., Merstham.

Dorothy Dann.—A pretty single-flowering variety of bright bronzy terra-cotta hue. A.M., R.H.S., October 24. Messrs. W. Wells and Co., Merstham.

VERONICA SILVER QUEEN.

A shrubby veronica of dense habit, and with closely-set creamy leaves, each with a central green line. A.M., R.H.S., October 24. Messrs. W. Cutbush and Son, Highgate, N.

ASTERS.

Amethyst.—A large-flowering and late perennial aster of great elegance, with flowers as large as those of Climax, but scarcely of such good form. The colouring is bright lavender-blue, a livelier hue than seen in Climax. A.M., R.H.S., October 24. Hon. Vicary Gibbs (gardener, Mr. Edwin Beckett, V.M.H.). Aldenham House, Elstree.

Profusion.—A very free and graceful variety, the branching growths carrying numbers of long, slender branchlets, each crowded with small whitish flowers. A beautiful aster. A.M., R.H.S., October 24. Hon. Vicary Gibbs.

PLUM COE'S VIOLET.

A handsome late dessert plum, combining excellent flavour with striking appearance. The variety is said to be a sport from the famous Coe's Golden Drop that was raised by Jervaise Coe, a Suffolk market gardener, as far back as the end of the eighteenth century. The fruits are shaped like those of Coe's Golden Drop, and they are delicately suffused with soft purple over a greenish yellow ground, with a bright band of violet-blue down the suture. It is a good plum for a warm wall, and is a success under orchard house culture. A.M., R.H.S., October 24. Mr. J. Vert, gardener to Lord Howard de Walden, Audley End, Saffron Walden.

DAHLIA DELICE.

An extremely beautiful dahlia of the true decorative type, carrying shapely flowers on stout stems. The plant is, we understand, of excellent habit for garden decoration, while its charming pink shade will render it a favourite for home decoration. A.M., R.H.S., October 24. Messrs. Carter Page and Co., London Wall, E.C.

THE REMOVAL OF PLANTS.

The individuality displayed by plants in their attitude towards removal, manifested as it is by their resentment, indifference, or appreciation, is scarcely less marked than in different phases of their normal life-history, and it is only by patient observation and experiment that we can get to know how they like to be treated in regard to this often necessary operation, for plants not only differ in the time of the year they most readily submit to it, and in the way in which they like it done, but vary in their likes and dislikes according to the conditions under which they grow. In dry, sandy soils, for instance, many plants do better if moved in October or early November, so that they may quickly get hold of the soil, which, in such a case, has usually still a considerable amount of warmth at this season, while similar plants in a wet clay soil will sometimes stand a better chance if left undisturbed till the spring, such a soil retaining little warmth after October, while, when newly moved, it holds more water through the winter than it would do otherwise, and is a better harbourage for slugs, which so often seem to prey on newly moved plants in preference to others.

In the case of the light soil, the plants will be getting established in November, so that they will be better able to stand a dry spring; while, in the other case, where the soil is not very likely to get really dry before the middle of May, there are two sides to the question at least. Some plants, too, which are not perfectly hardy, such as pentstemons and antirrhinums, will often, in some soils, stand the winter if left where they have been growing during the previous month or two, or more; but if moved in the late autumn they generally succumb. This seems not to be due to the freezing of the roots, and so to the stoppage of the water supply during sharp frosty weather with drying east wind, as one might suppose, for it is often observed that the moving is just as unfavourable to their standing the winter when it is a very mild one. It may possibly be due to the diminished vitality owing to the moving, as the flowering of Coreopsis grandiflora and Iceland poppies, both doubtful perennials, lessens their chance of standing the winter, presumably by lessening their vigour of growth, as it undoubtedly does.

Another aspect of plant removal is the fact that, while many may be moved successfully at almost any time, even, in some cases, when they are in the full vigour of spring or summer growth, others either resent being moved during the resting season, or do better if moved when growth is active. An inexperienced man looking at a rose tree in full leaf at the end of October would say that it would be better to wait for the leaves to fall before lifting it, yet it is a fact that rose trees may not only be moved with impunity at this season, if replanting is not delayed by a journey, but appear scarcely to feel the move. On the other hand, German irises, which, having a certain amount of foliage to keep the roots active during the winter, one would think, might be moved at any time between autumn and spring; yet, with a view to next year's display, are better moved during the latter part of July or early in August, according to the dryness of the season, and kept watered till they have recovered. They begin to make their growth for next year soon after they have flowered, and if they get established in their new position during September they will generally flower well the following season.

Many plants, especially alpines, seem to go to rest from October to March, or even from September to April, which is doubtless the survival of their method of adapting themselves to being buried underneath the snow during this period in their native habitats. Some of them are better moved even in flower than in late autumn, as they can be mulched and taken care of during any dry weather that follows, when they will become well established for another season. Some of the campanulas, such as C. carpatica and C. turbinata, and perhaps the mountain species generally, resent being moved in the late autumn, sometimes hardly recovering after it, whereas they can be moved in April with impunity. If the rock garden generally is overhauled in the latter half of August, when such replanting becomes necessary, choosing damp weather for the operation, it will suit the majority of plants better than any other time, and they will have time to re-establish themselves before they go to rest. The long-spurred columbines, too, though they seem to move so well in the late autumn with a large ball of earth and fibrous roots, yet never really recover from the check which it gives them unless the conditions are very favourable afterwards. If they cannot be moved in August, or early September, they are best left till March or April.

Herbaceous plants which finish off their growth in July or August are best moved then, if at all. Chinese pæonies will feel the move a good deal, whenever it is done, but they will feel it less in August than a couple of months later. The same with

Dielytra spectabilis, delphiniums, and gypsophila all bad subjects to move. The Japanese anemone—equally bad—is best moved in early October, if it must be moved at all. With such plants as these it is a good plan to have a box of bonfire ashes handy to put round the roots, as the fine particles get in close contact with the few rootlets they have and help the plants to make a new start. Fortunately the majority of our spring-flowering plants are a contrast to these in this respect, as they can be moved at any time from September to April, though early October is doubtless best with most of them.

There is one point which is often neglected in moving plants, and that is, taking note how the roots grow in the soil, e.g., horizontally or vertically, or whether the plants have a tendency to get constantly deeper in the soil or further out of it, etc. The object should be to replant them so that the roots are arranged after moving as they were before, while if the plants tend to get nearer the surface, as, for instance, with white lilies, tall phloxes, and many surface-rooting perennials, they should be planted a little deeper than they were before, and vice versa. Want of observation of these peculiarities of plants doubtless accounts for many failures, for when plants have acquired a certain habit of rooting owing to the conditions under which they were developed, it is not to be supposed that this character can be altered all at once with impunity. This is especially noteworthy with alpines and rock plants of all sorts.

Closely allied to this subject is the keeping of bedding plants in pots until they are unduly root-bound. It is not very much trouble to give the plants a decidedly better start if, when bedding out has to be delayed with any particular plants, they are turned out of the pots and planted in shallow trenches in some part of the kitchen garden, when the roots, instead of going round and round the pots, will spread out in all directions, forming a sort of wig, and be just ready to go ahead when put in their flowering positions.

A word in conclusion on moving plants in dry weather. It should be avoided, if possible, as regards dryness of air, but it is not unusual to have the soil very dry during late August and September, which, as pointed out above, is a very favourable time for moving many plants. The first thing to do is to thoroughly soak the plants before lifting them, and to do this may need two or three waterings spread over as many days. No less important is it to pour water into the hole before putting the plant in its new place, a watering of the surface after the plant is put in rarely moistening the roots properly when the soil is dry. This applies, too, when bedding out in a dry soil in May and June. When any plants have to be taken up with very little earth on the roots, it is a good plan to dip the roots in water before planting. P. C.

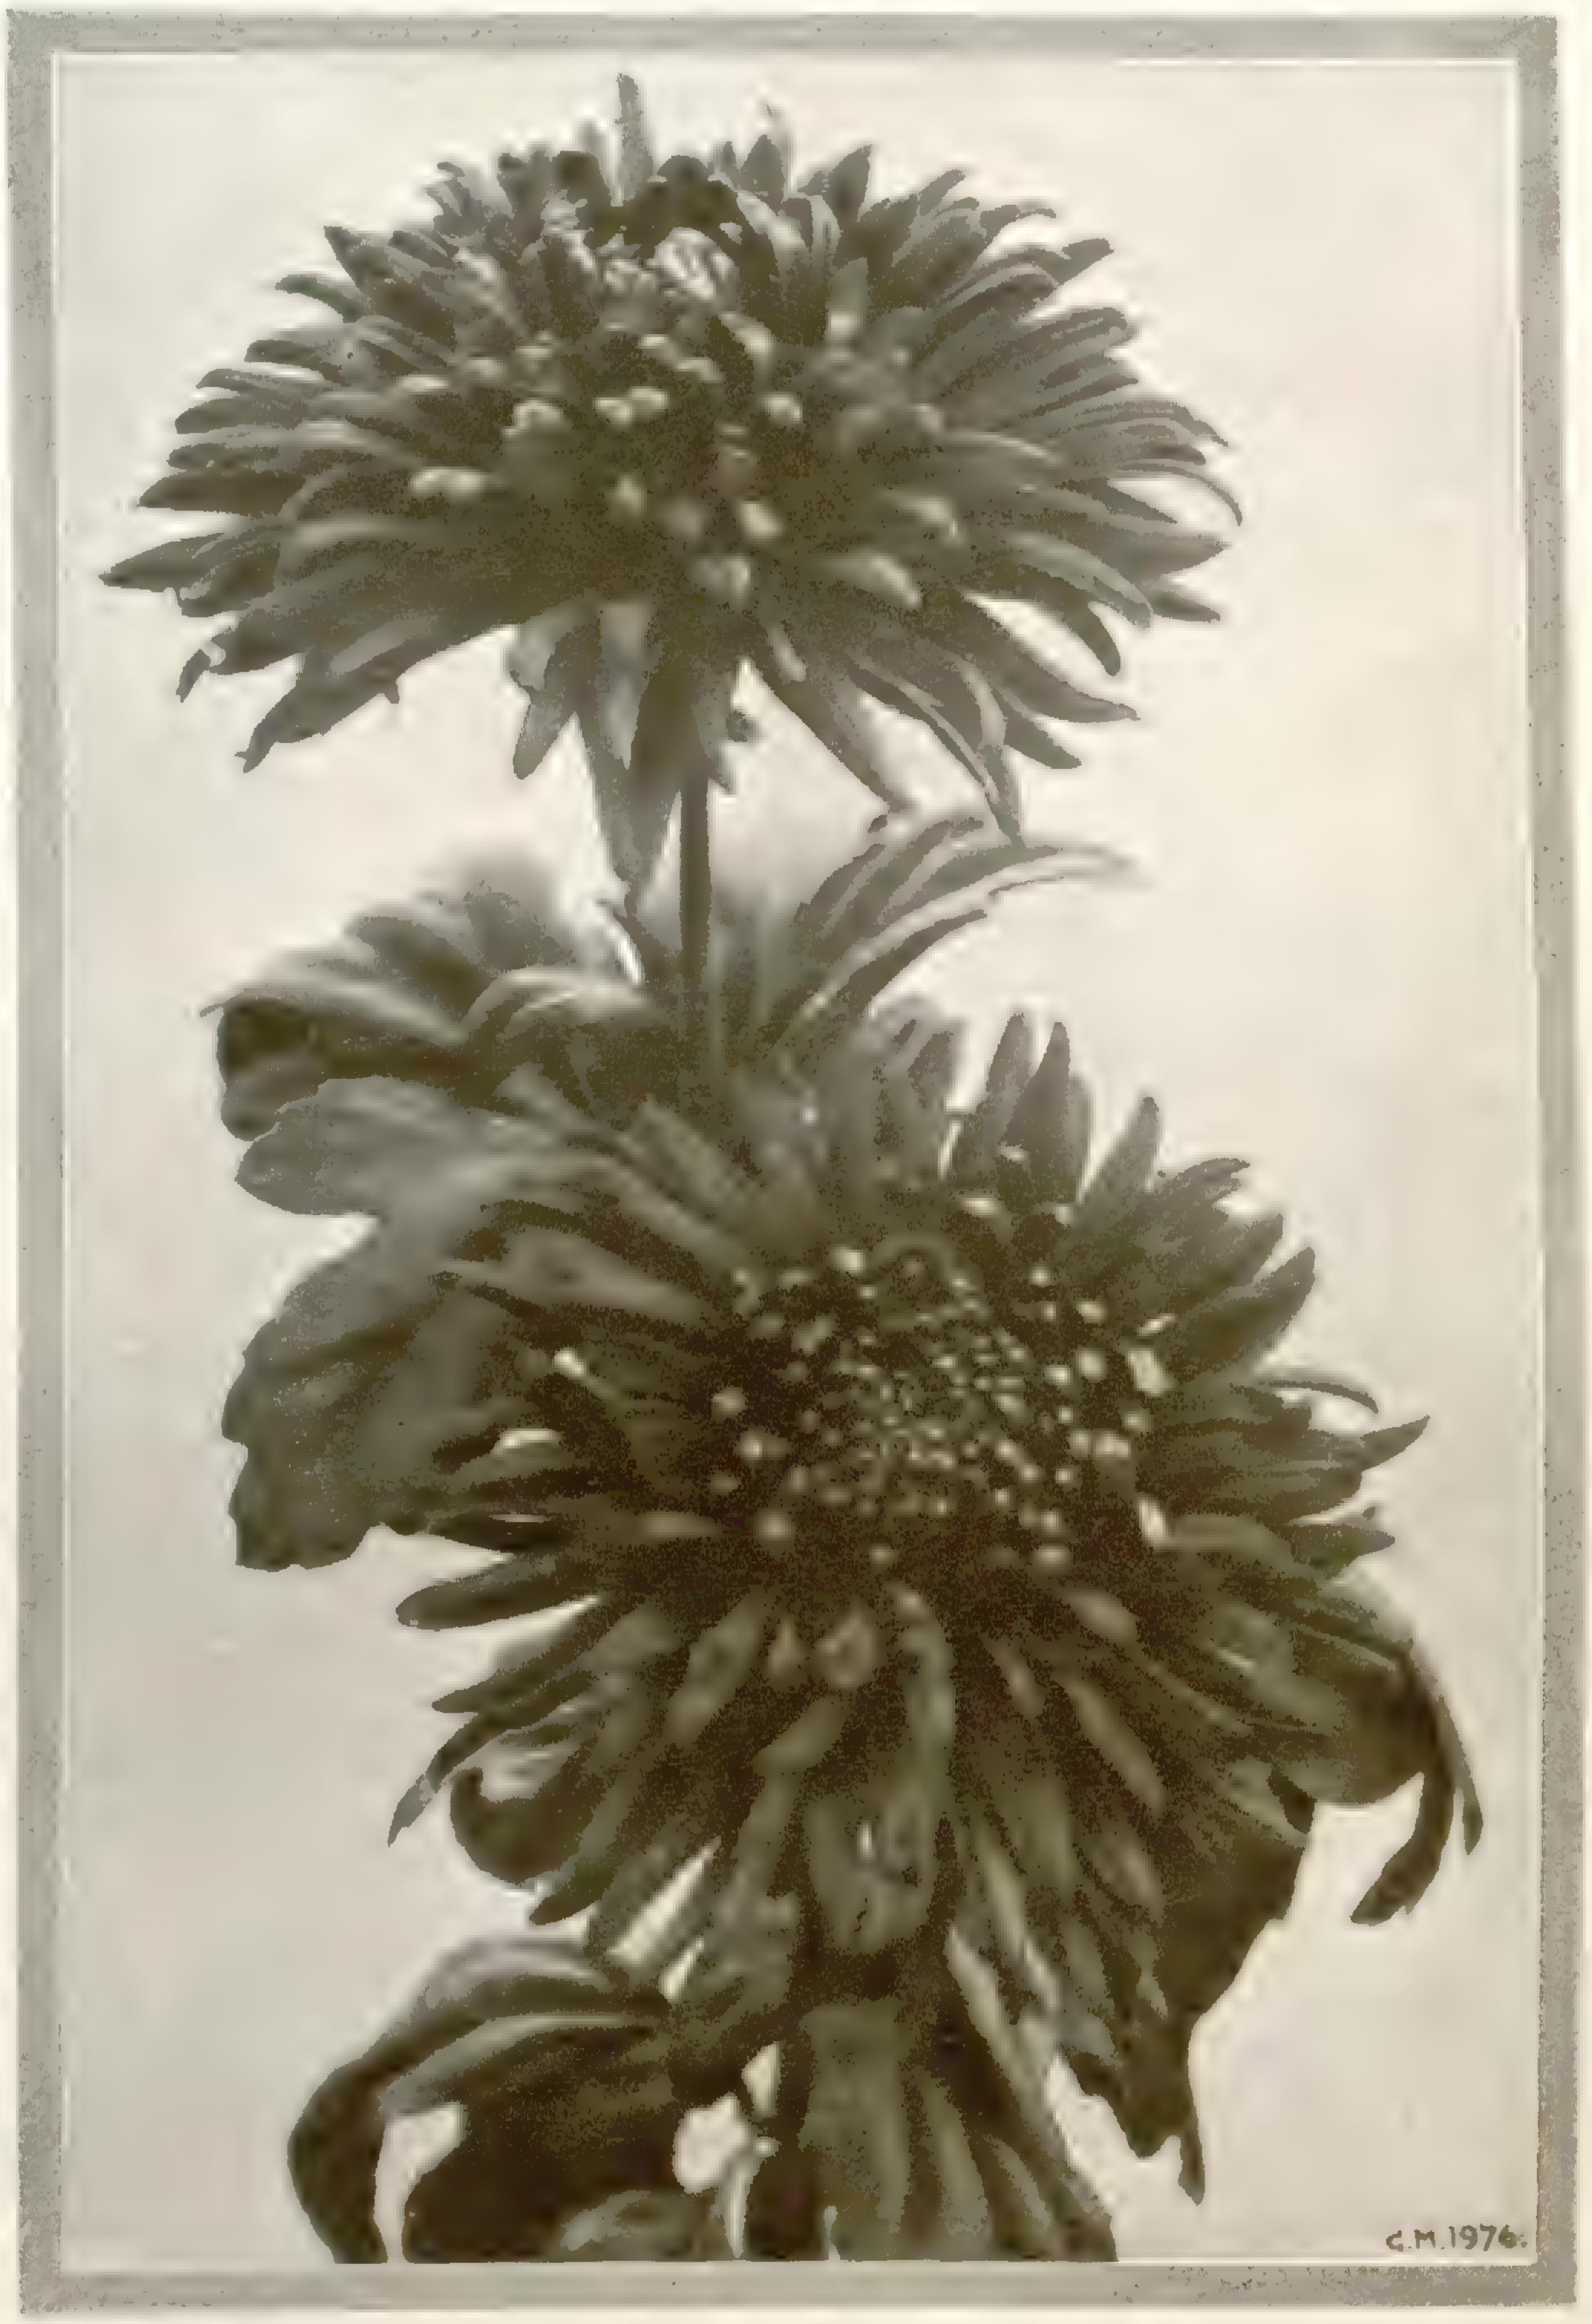
Apple Benoni.—If Mr. Markham has not grown this apple, I would strongly advise him to do so. Succeeding Worcester Pearmain, and ripening before King of the Pippins, or Blenheim Pippin are ready, it fills a gap, as we have no really good flavoured apple at that period. In this way Benoni is most valuable, and the flavour at the end of September and in October is quite first-rate, while in appearance it is handsome, being heavily striped and flushed with crimson on a yellow base. In shape and size it much resembles King of Pippins. In some seasons it is a shy bearer; the trees should be worked on the paradise stock, and grown as a bush, and the branches kept thin. It is of American origin, and was introduced here by Mr. Rivers.—E. M.

FRUIT FROM A NEW GARDEN.

From the point of view of the gardener, especially if he is fond of fruit, the great disadvantage of building oneself a house, or buying or hiring a newly-built house, is that one has to convert a field, or a piece of one, into a garden, and during the process one grows older, and is dependent in the meantime upon the greengrocer for one's supply of fruit. If one has been accustomed to growing fruit for oneself this is so extremely unsatisfactory as to induce one to take a house a few years old in preference, even if it is lacking in some of the modern conveniences. Growing our own fruit makes us very fastidious, especially in the matter of soft fruits, while with apples and pears it is scarcely less difficult to buy them of the quality we have been accustomed to, partly owing to the premature gathering to which they are usually subjected, and partly to the rough handling and indifferent storage which they have received. This is an effective answer to friends who would dissuade us from planting fruit trees by telling us we can buy the fruit more cheaply. The man to whom an apple is an apple and nothing more can doubtless do so, but not the man who has once grown apples for himself. Therefore let us consider the ways in which we may minimise the disadvantages in this respect of a new house.

Strawberries, Loganberries, and Raspberries.

The first fruit that will occur to everyone is the strawberry. Young plants bedded out at the end of the summer or early in autumn will yield fruit, sometimes of the finest quality, the following summer. If not planted till the spring little, if any, fruit must be expected the first season. The raspberry is only less quick in making a return. I have planted canes late in March which have made such good growth the following summer that they have produced an excellent crop the year after—that is, fifteen months from the time of planting. In this case, however, both summers were damp, and, generally speaking, they should be planted four or five months earlier to ensure the same result. This is assuming the canes are cut down to within a foot of the ground at the time of planting, or before growth begins, and kept mulched during the summer. The loganberry, which seems likely to grow in popularity, produces fruit equally quickly. The two last-named fruits will be in their prime the third summer after planting, producing



CHRYSANTHEMUM BRONZE GOACHER'S CRIMSON.
Sport from Goacher's Crimson, the flowers red-bronze, suffused orange. A.M., R.H.S., October 24. Messrs. W. Wells and Co., Merstham.

fruit in as great abundance as they ever will, while the quality may be even finer than at any later period, assuming, of course, that the seasons have not been abnormally dry; or, if so, that the canes have been well looked after.

Currants and Gooseberries.

Gooseberries may be had almost as quickly as raspberries. Ordinary bushes, it is true, are three or four years in coming into good bearing, but we may have a moderate crop very quickly in two ways. If three or four-year-old bushes are planted late in October they will bear a few berries the first year without injury if the young growth is well shortened at the time of planting, and they may be set about three feet apart, so that many trees can be put on a small space. Alternate trees can be taken up and planted elsewhere after three or four years, or thrown away, as they are very cheap. In this way a very fair crop of fruit may be obtained from even a small space eighteen months after planting. If the cost of the trees is urged as an objection it must be borne in mind that ripe gooseberries can never be bought in good condition, even if they can be bought at all, which is rarely the case, though gooseberries for sale are often ticketed as such. Another way in which fruit can be obtained even more quickly than in the way suggested above is by the planting of single cordons in rows nine inches to a foot apart in the row. If three or four-year-old trees are planted late in October in good soil a fair crop—say, from half a pound to a pound to the tree—may be expected the following summer, and the second year twice this amount. As twenty cordons take up little space—say forty square feet or less—this is not a bad return from the ground in a short time, while the cost of the trees may be put down at ten to fifteen shillings.

The other bush fruits—black, red, and white currants—are slower in coming into bearing, and are not of sufficient value as compared with shop fruits to make it worth while to adopt exceptional methods to obtain an early return.

Plums.

To come to the consideration of fruit trees proper, we cannot expect quite such quick results in fruiting, though here results are much quicker than our forefathers ever dreamed of. Let us deal with plums first. Everything depends upon the stocks on which they are budded and upon the choice of varieties. The Victoria, for instance, may be expected to yield some pounds of fruit, planted early in November against a wall or fence, the second summer. For speedy returns this is probably the best of all to plant, though as a dessert fruit it is only of very moderate quality unless very well ripened. As single cordons plums yield very good results in the minimum of time if the most prolific varieties are chosen, a small crop being often produced the first summer after planting, and a very fair crop the second summer. But no such results must be expected from the greengage, or, indeed, any of the gage section. These have to be waited for, and they are worth it. Such a variety, however, as Early Prolific (Rivers') is often literally clothed with fruit the second summer after planting in cordon form, as also the Czar, Belgian Purple, Monarch, and some others. These four varieties would keep up a succession of fruit for two months, August and September, and though generally classed as culinary varieties, they are all very fair eating when fully ripe. The only two dessert varieties which come near these for early fruiting are Jefferson and Denniston's Superb, which, if one happens to have very well-grown trees on the most favourable stock will sometimes do well the second year. If any of the trees—cordons or otherwise—show any tendency to rank growth the first season, they should be taken up and root-pruned just before the leaves have all fallen. Of course, protection from frost is assumed when speaking with such confidence of early fertility. The planting of cordons in this way should only be supplementary to other forms of tree, which will be in their prime when the cordons are getting worn out, if cropped very heavily year by year.

Pears.

Pears are less likely than any fruit to yield early returns, for though cordons of the most fertile varieties on the quince, will sometimes produce a few fruits the first season, and more the second season, we must not pay too much heed to what is written about cordon pear trees paying for themselves the first year. I have never had such an experience with any fruit tree. Cordon pears often take on too much growth, and consequently need root-pruning to get them into good bearing. By planting them obliquely against a wall or fence, or artificial support of any kind, two feet apart, a good many trees may be put in a line of twenty yards, and, taken together, some amount of fruit may be expected the second year. If the expense of planting is considerable, on the other hand, the fruit is of the highest quality. The following are almost sure bearers, as well as sorts that should not be left out of any collection, however small: Louise Bonne of Jersey and Marie Louise d'Uccle (October), Emile d'Heyst, and Durondeau (November), and in warm situations Beurré Superfin (September), Doyenné du Comice (November), and Winter Nélis (December). The last three are possibly the finest trio of pears that could be named.

Apples.

Lastly we must consider apples. Much quicker results can be obtained from culinary than from dessert varieties of these, though most of the former are, by real apple lovers, considered fine eating when well grown, carefully stored, and fully matured. Some may object to the trouble and expense of growing these when they can be bought so cheaply. Well, the trouble is a great pleasure to those who make a study of it, and a source of never-failing interest; the expense is not great, and is generally paid for in a very few years at the most; while as to quality, even for cooking, the bought apples, being usually picked before they are mature, often put straight into barrels before they have sweated, and generally roughly handled and badly stored, are not to be compared with those from one's own garden, even allowing for the partiality of the grower. There are two varieties which, planted in quantity as bushes, either on the paradise or on the free stock, will keep up a good supply of apples for the kitchen from August to April, and these are Stirling Castle and Lane's Prince Albert. They are wonderful bearers, and if planted in good soil as soon as the leaves fall—there is no fear of their growing too strongly—may be expected to produce a fair amount per tree the following season. Stirling Castle is often ready for use late in July, and continues in season till October, middle or end, according to the season. Lane's Prince Albert, when well matured, becomes very fair for eating in April. If a more particularly mid-season sort is wanted, Seaton House might be mentioned, which is at its best from October to December, and is very fertile. These three are small growers, and may be planted eight or nine feet apart as a permanency, or four or five feet temporarily, and alternate trees transplanted or done away with after four or five years. As for dessert varieties, as stated above, none give crops so speedily; but for fairly quick returns, for a small crop the second or third year—not often the first—the following might be planted: Worcester Pearmain (September), Fearn's Pippin (November to February, of moderate quality), and, in warm situations, King of the Pippins (October to December) and Cox's Orange Pippin (November and December). All these are suited to the cordon form, and on a given space more fruit would probably be obtained from trees of this form for the first five years than from bushes.

The recommendations in the above notes are made solely with the view of speedy returns from a newly-made garden, and the planting suggested should be quite independent of, and supplementary to, the planting of fruit trees for future results. The sorts named are not necessarily the best for all purposes, but commend themselves by reason of their great and early fertility. Where results are spoken of the first season after planting it is assumed the trees are planted late in October or early November, for if not put in till after Christmas nothing can be expected till the second season. It is better, however, to plant even early in April, supposing the trees to be looked after in a dry summer, than wait till the following autumn, as better results may be expected the next year.

Alger Petts.

CLEMATIS DAVIDIANA.

This is one of a number of kinds of clematis of sub-shrubby habit, which form a distinct group, characterised by large inflorescences of tubular blue flowers. It is of Chinese origin, and was named by Franchet in compliment to the great French missionary and plant collector, Abbé David, who spent many years of his life in the Chinese Empire; and with the aid of herbarium specimens brought to the notice of Western botanists many of the hitherto unknown floral treasures of the East. As a garden plant it is found between two and three feet in height, numerous stems rising from one common rootstock. The lower parts of the branches remain year after year, but the upper portions perish with the flowers. The compound leaves are larger than those of other clematises except those of one or two closely allied kinds, such as C. heraclesæfolia and C. stans, the terminal leaflet being nearly 6in. in length and 4in. wide.

About July buds are noticeable on the upper half of the current year's shoots, and as these develop, the end of each branch is transformed into a fine inflorescence, bearing large numbers of pale blue flowers, each one of which is about a-half to three-quarters of an inch long. To succeed with this species it is necessary to prune it back in February to within two or three buds of the base of the previous year's wood, and to keep the crowns well thinned out. Good loam, containing lime, will be found to form a good rooting medium.

W. Dallimore.

Apple Edward VII.—Instead of growing this apple, I would advise Mr. Day to grow Bramley's Seedling. While admitting that King Edward VII. is a good apple when you can get a crop, it is so much like Bramley's Seedling in many respects—appearance, quality, flavour, growth, and keeping qualities—that it is really not required, except by those who are fond of variety. This was the impression I formed of it when I saw it first at the autumn show at Birmingham some years ago, and that opinion has been emphasised by experience with it.—E. M.

WORK FOR THE WEEK.

◆

ORCHIDS.

DECIDUOUS CALANTHES.—These have their flower scapes well advanced, and, as the foliage will be decaying with their further development, some care is necessary in affording root moisture. It is desirable that these orchids should receive enough water to assist them to develop their spikes and expand their flowers. No hard and fast lines can be laid down as to the quantity of root moisture to be afforded. Calanthes are, perhaps, grown under more varied conditions than any other orchids, for if no others are cultivated in a private garden we generally find some deciduous calanthes, and in most cases we find them grown with a considerable amount of success. The aspect of the house makes a great deal of difference in the evaporation of moisture. We never permit our plants to remain in a dry state at the roots for any prolonged period until after the plants have passed out of flower, but care is observed not to allow the soil to become in any way stagnant. Calanthes should be placed in a position within a reasonable distance of the roof glass. It is not desirable that the flowers should be clustered closely together on the spike, or a great deal of the grace is lost; while, on the other hand, if allowed to become unduly drawn, the spaces between the flowers are too great. Plenty of light should be afforded.

CALANTHE SEEDLINGS.—As with many other kinds of orchids, the seeds of calanthes sown in the spring and early summer have been late in germinating, and consequently many of the seedlings are only just ready for transplanting. It is a difficult matter to deal with seedling calanthes if they are permitted to remain on the old seed bed during the winter, for the small bulbs which are produced in many cases the first year are difficult to find after the tiny foliage has gone, and there is a danger of their destruction on the dried-up compost necessary for the resting period of the older plant. We find it a good plan to transfer several seedlings together into small pots. The pots being filled with fibrous peat and chopped sphagnum, and surfaced with some finely-chopped sphagnum moss. If the seedlings are pricked off into store pots now they will root into the potting material, and can be afforded careful attention. There is also the advantage, if the store pots are placed on a shelf or near the glass in a warm house, that they commence to grow earlier in the year, and they may then be potted singly into small pots, and greater progress is obtained during the next growing season. — H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CHRYSANTHEMUMS. — These are now making a fine show, and a little heat will be found necessary on damp days to prevent the blooms from damping. This, if worked together with the ventilation, will maintain a suitable atmosphere. The latest flowering varieties should be removed indoors, and placed in a cool house, where they will require less attention in case of frost. Continue to disbud these late varieties, leaving only one terminal bud on each shoot. Manurial assistance should be given until the buds show colour, when the supply of liquid or other stimulants must cease.

BIENNIALS. — Campanula pyramidalis and Canterbury Bells, which are required to flower early next spring, should be taken up with a good ball of soil and potted. A 32-sized pot will be found large enough, and will allow for a shift later on. A cold frame is a suitable place in which to winter the plants. After they have recovered from the check occasioned by potting they will not require much water, as a more healthy state is maintained if they are kept rather dry during winter. Coreopsis grandiflora, if treated under similar conditions, will prove a very valuable addition to the early-flowering plants for conservatory decoration.

PRIMULAS.—During the flowering season the atmosphere of the house in which primulas are staged should be kept rather drier than in the growing season. Primula obconica and its two varieties, P. obconica alba and P. obconica rubra, require a rather higher temperature than that given to P. sinensis, to secure the best results. P. kewensis, being very nearly hardy, thrives best if placed in a house where fire-heat is given only during very severe weather. Occasional waterings with diluted soot water will greatly benefit the plants.

HARD-WOODED PLANTS. — If not already done, these plants should be housed immediately. The majority of plants coming under this heading are essentially what are known as cool greenhouse subjects, and, greatly resenting artificial heat, and being unable to withstand frost, their cultivation during the winter months requires careful attention. When artificial heat is found necessary, ventilation should also be afforded. Watering must be carefully carried out, never allowing them to become dry at the roots, and at the same time exercising care in the other direction. The genistas are especially averse to overwatering during the cold season, this causing the foliage to turn yellow.

CAMELLIAS are now swelling up their buds, and, if planted out, it will be necessary to examine the borders to make certain that they are in a proper state as regards moisture, as drought is one of the chief causes of buds falling. Disbudding may be done where buds are thickly set, doing the work gradually so as not to cause a check to the trees.—A. GRUBB, Porter's Park Gardens, Shenley, Herts.

HARDY FRUITS.

PEACHES AND NECTARINES.—The late heavy rains have so thoroughly soaked the ground that transplanting fruit trees may be at once commenced. Peaches and nectarines should be the first to receive attention, as, unlike many other fruits, if moved with care an abundant crop may be carried the following season. Stone fruits should always be provided with plenty of old lime rubble, not only because the trees require lime to form their fruits, but also as an aid to keeping the soil sweet and wholesome; no fruits being more impatient of sour or water-logged borders than peaches and nectarines, or so likely to suffer from an excess of moisture about the roots.

RASPBERRIES.—Plantations of raspberries are often allowed to occupy the same site for a number of years, and in many instances, with the aid of an annual top-dressing, this is found to suit their requirements, but where the strength of the plants annually deteriorates, it is obviously time to provide a new situation for them. This may be done at the present time. The soil should be thoroughly trenched, working in at the same time abundance of wood ashes or burnt earth from the refuse heap, and, if the soil be poor, well-rotted manure should be well mixed with the bottom spit. Strong healthy suckers with plenty of fibrous roots attached should be planted firmly in rows or clumps; if in rows, which is the most usual method, such rows should be at least 5ft. apart, allowing about 2ft. from plant to plant, or even more; nothing is to be gained by planting too thickly. The canes should be left until early spring, when it is most essential for the future wellbeing of the plantation that they should be cut to within two or three inches of the crown, thereby forfeiting a crop the first year after planting.

NUTS.—The Kentish cobs are not so generally cultivated outside of Kent and the adjoining counties as might be expected considering their value and usefulness as an adjunct to the dessert table. Who among the younger folk does not enjoy the big fat kernels of a cob nut? To grow these successfully the trees will need cultivating quite as highly as the more popular fruits. The plantation should be given the most open position, well cultivated, and kept as free from weeds as possible. Manurial dressings should also be given occasionally. When storing the nuts a cool, moist place should be afforded, where they will keep sound and plump for months. Care must be taken that rats or mice cannot reach them, or the whole store will disappear in an incredibly short time.

THE FRUIT ROOM.—Apples and Pears will need a little attention, and must be carefully looked over, removing all decayed fruits, or many others that come into contact with them will be affected. All specked fruits should be laid aside for immediate use. Continue to keep the floors moderately moist, and decrease the ventilation, keeping the room at as even a temperature as possible.—J. WHITTLE, Cheveney Gardens.

THE KITCHEN GARDEN.

SEAKALE.—The crowns will be matured by now, and fit to lift for forcing purposes. Have a batch of plants lifted, the larger roots reduced, and place them in the mushroom house. The early batches are often somewhat slow to commence growth, and we find a satisfactory plan is to plant them in boxes about ten inches deep and to hold from two to three dozen heads. These boxes can be placed in warm and convenient positions, watered with warm water, and otherwise treated better than if planted out in a bed. Syringe the crowns twice each day, and keep a continuously moist atmosphere by damping down the floors, etc., of the house.

ASPARAGUS.—Where this is in demand through the winter, and a supply of crowns has been prepared for forcing, a beginning may be made by lifting a quantity and placing them in heat. A heated brick pit is very suitable for forcing this vegetable, and a mild hotbed largely consisting of leaves made firm, with about nine inches of sandy soil as a planting medium, will afford a natural warmth for the roots, while the top water pipes will produce the requisite temperature of 55 to 60 deg. Water the plants copiously with tepid water and daily syringe the inside walls to produce a moist atmosphere. Failing such a pit, a hotbed made up with sweetened manure and leaves, with a wooden frame placed over it, will serve, but is not so convenient to work, especially during extreme cold weather.

SPRING CABBAGE. — Plants that were put out as advised will now be well established and growing freely. It will much benefit them if the soil is pointed over and then drawn up to their stems to steady them during windy weather, and to give protection when sharp frosts arrive. In places where the plants are not growing away as desired apply a dressing of nitrate of soda to the soil.

TURNIPS.—The late-sown crops will in many cases be of serviceable size,and the bulbs should be pulled and stored in sand for use. If the ground is not immediately required the smaller bulbs can be left to grow. The Orange Jelly variety, sown in early September for latest winter use, has, owing to the exceptional warm weather, grown to maturity earlier than usual, and should be similarly treated.

HERBS.—From now onward it will not be safe to trust to an outside supply of some herbs; pot up or box some plants of tarragon and mint. It is sometimes a good plan to sow a few boxes with chervil in cases where it is largely used for flavouring salads or other purposes. Do not force the plants very quickly, but grow them in a temperature of about 50 deg., or the growth will be thin and worthless.

GENERAL REMARKS.—Continue to remove all finished crops from the land, such as runner beans, the latest peas, vegetable marrows, etc.; and make a thorough clearance of weeds from the quarters and walks. Finish up the clipping of hedges and give everywhere, as far as possible, a neat appearance. This will give time for the pressing work of manuring and trenching the quarters as they fall ready to be dealt with later. —CHARLES FLACK, Cholmondely Castle Gardens.

EXHIBITIONS AND MEETINGS.

◆

Croydon.

One of the earliest of chrysanthemum shows is that held at Croydon—this year, on October 25 and 26—and as on several previous occasions, the Adult School Hall, Park Lane, was the place of exhibition. The show was not so extensive as usual, owing to the curious fact that, despite the hot season, large exhibition blooms are later than usual. The quality of the flowers shown was excellent, and the same remark applies to the vegetables and fruits.

There was but one entry in the class for thirty Japanese blooms, distinct, staged in six vases; this is unfortunate, indeed, the class is an unfortunate one, because, unless there are three competitors, the first prize does not carry with it the twenty-five guinea cup. Mr. Beeson, gardener to J. Newton Mappin, Esq., Headley Park, Epsom, was the exhibitor, and his best blooms were of Mrs. A. T. Miller, Miss Elsie Green, G. Mileham, W. Beadle, Lady Letchworth, Master David, Rose Pockett, and Walter Jinks.

For fifteen blooms in vases and in not fewer than three varieties, Mr. Beeson was a capital first with five grand flowers each of Lady C. Letchworth and Mrs. A. T. Miller, four of J. Lock, and one of Rose Pockett; Mr. J. T. Tubb, gardener to J. D. Alexander, Esq., Sevenoaks, came second, and Mr. Fleet, gardener to J. A. Allen Esq., Wynnstow, Limpsfield, was third.

The chief Borough of Croydon class was for fifteen Japanese blooms, in three or more varieties, and here the President's Cup is added to the first cash award; there were five competitors, and Mr. Howarth, gardener to Wickham Noakes, Esq., Selsdon Park, was a capital first, with fine examples of Reginald Vallis, Mrs. G. Mileham, Lady Talbot, J. Peed, Mrs. A. T. Miller, Pockett's Crimson, and Leslie Morrison. Mr. R. Gladwell, gardener to A. Gosheron, Esq., Tennison Road, second; and Mr. G. Edwards, Windmill Road, Shirley, third.

There was a capital competition in the class for six vases of decorative chrysanthemums grown in the open: Mr. F. Finch, gardener to G. H. Fisher, Esq., Godstone Road, Purley, was placed first with large sheaves of Normandie, Tapis Niege, Madame Lefort, Diana, Provence, and Roi des Blancs; Mr. G. Lawry, gardener to Mrs. Williams and Miss Blake, Duppas Hill, second; and Mr. E. Dyer, gardener to E. Wood, Esq., Church Road, Upper Norwood, third.

For the best set of ten blooms, in one or more varieties, Mr. L. Gooch, gardener to T. Wickham Jones, Esq., South Norwood, led with Mrs. G. Mileham, J. Peed, and Valerie Greenham; Mr. W. Paulley, gardener to Dr. Jackson, J.P., Thornton Heath, came second; and Mr. A. Dyer, gardener to E. Wood, Esq., Church Road, Upper Norwood, third. Mr. C. C. Hunt put up a capital three vases of single chrysanthemums, and won a first prize therewith.

In the smaller classes Mr. T. Finch scored for five incurved blooms, with large flowers of Buttercup. Mr. Godly, gardener to T. B. Vaughan, Esq., Beulah Hill, led for five Japanese blooms in one vase.

In the amateurs' division, the silver cup for ten Japanese blooms arranged in two vases, was won by Mr. L. White, 34, Braemar Avenue, Thornton Heath; Mr. C. Hunt, Stroud Road, Woodside, coming second.

Two competitors came forward in the class for a miscellaneous group, and chief honour fell to Mr. J. W. Colyer, gardener to A. R. Allen, Esq., Wandle Court, Beddington, who used chrysanthemums, odontoglossums, cypripediums, Begonia Gloire de Lorraine, and streptocarpuses, among crotons, ferns, and palms; Mr. D. Love, gardener to Mr. Alderman Allen, Coombe Cliffe, second, with a display lacking in arrangement. For three specimen plants, single varieties, Mr. T. Finch led with large examples of Mary Richardson, but not half the blooms were open, a failing noticed in other plant classes and due to the peculiar season. There was but one group of chrysanthemums, and for this Mr. A. Edgerton, gardener to W. Valder, Esq., Beechwood, Croham Park Avenue, was awarded a second prize.

Mr. J. W. Colyer, second, for a pair of bunches of grapes with Muscat of Alexandria, and Mr. Lintott was second with Gros Maroc. In the open class for nine dishes of apples Mr. Rawlings, gardener to H. Goschen, Esq., Heathfield, Addington, led with good specimens of Tower of Glammis, Gascoigne's Scarlet, Peasgood's Nonsuch, Lady Henniker, Bismarck, and Lord Derby; Dr. Jackson was second, and Mr. W. Lintott, gardener to Sir Walpole Greenwell, Bart., Marden Park, third; five entries.

Six dishes of pears was another good class, and here Mr. W. Lintott scored with Beurre Hardy, Marie Louise, Beurre Diel, Pitmaston Duchess, Doyenne du Comice, and Beurre Bosc; Dr. Jackson second, and Mr. B. J. Kingsley, Holmwood Park Gardens, Holmwood, third. Mr. Gledwell, Mr. Rawlings, Dr. Jackson, and Mr. Jeal, gardener to N. Waterall, Esq., Waddon, were all prominent winners in other fruit classes.

Mr. J. T. Tubb, gardener to J. W. Alexander, Esq., Sevenoaks, led in the open class for a collection of nine kinds of vegetables, winning with good onions, cauliflowers, carrots, runner beans, celery, potatoes, Brussels sprouts, beet, and parsnips; Mr. W. Lintott came second, and Mr. B. J. Kingsley, Holmwood, third. In the local class for six kinds of vegetables Mr. O. Jeal came to the front, followed in order by Mr. Finch and Mr. J. Johnson, gardener to Mrs. A. Crowley, Bramley Hill. Mr. H. E. Marden led in another class, and scored also for onions.

Mrs. S. H. Cole, Addiscombe Avenue, won first prize for a table decoration of yellow and soft bronze chrysanthemums; Miss Bashford, Barron Hedges Farm, Carshalton, second, with a very bright scarlet, and Mrs. Edwards, Warwick Terrace, Sydenham, third. For a centrepiece filled with chrysanthemums, Miss Bashford beat Mrs. Cole, and she used small coloured vine leaves and red oak leaves skilfully with her flowers. Miss Bashford was also successful for a basket of chrysanthemums.

There were several non-competing exhibits. Mr. Thomas Butcher, South Norwood, decorated the platform with chrysanthemums, palms, etc., and contributed a table of floral designs. Messrs. W. Wells and Co., Merstham, put up a very bold and bright exhibit of single and big Japanese chrysanthemums and perpetual carnations. Messrs. E. W. and S. Rogers, Croydon, contributed seed potatoes, etc., and Mr. Oxtoby, gardener to J. J. Reid, Esq., Coombe Lodge, exhibited two dozen bottles of bottled fruits.

Hereford Fruit and Chrysanthemum Society.

This society held its annual show on October 25 and 26 in the Shire Hall, Hereford. Hardy fruits, as is invariably the case at this show, were the leading feature, as may be gathered when it is remarked that upwards of fifty classes were provided for apples alone. Grapes were also creditably staged, and so were vegetables, and agricultural produce, in the way of roots, grain, hops, etc. Trade exhibits were not numerous, though those present did much towards making the show attractive and a success.

In the class for a collection of fruit, six dishes, three good sets were arranged, the chief one by Mr. Liddle, gardener to Sir J. Cotterell, Garnons, who had Lady Downes and Muscat of Alexandria grapes, Coe's Golden Drop plums, Emerald Gem melon, Cox's Orange Pippin apples, and Doyenne du Comice pears. The second place was deservedly taken by Mr. Sykes, gardener to Colonel Henry, of Haffield. Mr. Stevens, gardener to Captain P. A. Clive, Whitfield, was the only exhibitor of Gros Colmar grapes, and staged medium sized, well-finished bunches. For any other black grape, Mr. Dunn, gardener to Mrs. Woodhouse, Burghill, scored with large bunches of Alicante; second, Mr. Sykes, with nice bunches of Gros Maroc. Five exhibitors staged in a class for any white grape, Mr. Roberts, gardener to P. H. Foley, Esq., Stoke Edith, being placed first with creditable Muscat of Alexandria; and Mr. G. R. Currie second with the same variety.

For fifty dishes of culinary and dessert apples, two exhibitors staged collections, and Messrs. Pewtress Bros., Tillington, easily secured leading honours with an excellent lot of clean, highly coloured fruit, some of their leading varieties being Tyler's Kernel, New Hawthornden, Pillington Court, Lord Hindlip, Newton Wonder, Flanders' Pippin, Belle Pontoise, Byford Wonder, Blue Pearmain, King of the Pippins, James Grieve, Baxter's Pearmain, Forester, May Queen, Knight's Russett, Allington Pippin, and Cox's Orange Pippin. Mr. Roberts was second, and staged a good representative collection. Of thirty dishes there were two lots presented, the first prize going to Mr. Powell, Warham Farm, who staged good, clean fruits, and some of his best dishes were King Edward VII., Annie Elizabeth, Bismarck, Newton Wonder, Lord Derby, Lady Henniker, Golden Noble, Beauty of Kent, Winter Pearmain, Lane's Prince Albert, Rival, Cox's Orange Pippin, Court Pendu Plat, and Hormead Pearmain. Mr. Taylor, gardener to J. Ridley, Esq., Putley Court, was a close second with a very similar lot of fruit. There were five sets staged in a class for twelve dishes of culinary apples, the Sellack Fruit Farm, Co. Ross, taking the coveted place with a fine set of large and otherwise fine fruits, in which Newton Wonder, Bramley's Seedling, Gascoigne's Seedling, New Hawthornden, Lane's Prince Albert, and Bismarck were especially fine. With an almost equally fine set F. Boddington, Esq., Burghill, was placed second; and Mrs. Woodhouse, Burghill, third.

Seven exhibitors staged eight dishes of dessert apples, which made a splendid class, with but little difference in the quality of the fruit shown by the prize-takers; Messrs. Getting and Newton, Ross, secured the lead with Cox's Orange Pippin, King of the Pippins, American Mother, Rival, Wealthy, etc.; second, Mr. Currie, gardener to the Rev. G. H. Davenport, Foxley; third, F. Boddington, Esq. Eight culinary and four dessert varieties found Mr. Bott, of Brunton, taking the lead amongst three exhibitors with beautifully coloured specimens of Blenheim Pippin, Cox's Orange Pippin, King of the Pippins, Charles Ross, Wealthy, Peasgood's Nonsuch, Annie Elizabeth, Belle Pontoise, Lady Henniker, Lord Derby, Bramley's Seedling, and Golden Noble. Mr. Currie took second honours, and C. B. Lee Warner, Esq., third. A class for recently introduced varieties was especially interesting, and here Mr. Powell, Warham, scored with Lord Hindlip, Rival, Charles Ross, Coronation, King Edward VII., James Grieve, etc.; Mr. R. W. Whiting, Credenhill, was second with a good set, including Hector Macdonald and Encore. For eight culinary market varieties Mr. Powell again led, while Messrs. Getting and Newton led for eight market dessert varieties, and the Sellack Company scored for twelve culinary and six dessert market varieties.

Among the single dish classes, of which there were nineteen, many of the best fruits and the most spirited competition were to be found. No less than thirty-one dishes of Blenheim Pippin were staged in its class, twenty-five dishes of Cox's Orange Pippin, and twenty-four dishes of King of the Pippins. The coveted champion positions were taken by the Sellack Company for the best dish of dessert apples in the show with Cox's Orange Pippin, and by Mr. Boddington for culinary apples with Stirling Castle.

Pears, though not shown in large quantity, were staged in fine condition. Mr. Currie was placed first for twelve dishes, and had splendid examples of Beurre Bosc, Beurre Diel, Marie Louise, Doyenne du Comice, Emile d'Heyst, Pitmaston Duchess, Thompson's, Glou Morceau, Winter Nelis, Conference, Durondeau, and Easter Beurre; Mr.

Parrott, gardener to A. W. Foster, Esq., Brockhampton Court, was a good second. Mr. Liddle, gardener to Sir John Cotterell, Garnons, scored for eight dishes with Doyenne du Comice, Beurre Diel, Nouvelle Fulvie, Easter Beurre, Pitmaston Duchess, Durondeau, Beurre Bosc, and Conference; Mr. W. D. Thomeley, gardener to General Clive, Perryston Court, was a close second. In the single dish classes Mrs. Bashill was first for Pitmaston Duchess; Mrs. Woodhouse, for Marie Louise; Sir John Cotterell, for Doyenne du Comice; and the Hon. Mrs. Wilmot, first, with Catillac, for any culinary variety. The champion prize was awarded to Mr. Liddle for a fine dish of Doyenne du Comice.

There was only one entry for a decorative group of fruit, viz., from Messrs. Pewtress Bros., who had apples of first-rate quality and variety staged in market boxes.

Of the two groups of miscellaneous plants, staged in a space of 12ft. by 7ft., that from Mr. H. Tribe, gardener to F. W. G. Williams, Esq., secured the first position; Mr. A. Liddle was the other competitor. Both groups were well arranged, and composed of well-grown graceful subjects.

Chrysanthemums were not largely represented, there being only six classes provided for them, and these confined to blooms arranged in vases. Mr. H. Tribe, C. F. Halford, Esq., A. G. Burney, Esq., Dr. C. S. Morrison, and Captain Clive were leading prizewinners. Baskets of ornamental foliage from hardy plants were arranged with excellent taste by Mrs. M. Offler, Hereford; the Hon. Mrs. Wilmot, and Mrs. Spencer, who secured prizes in the order named. Dinner-table decorations, confined to chrysanthemums, and suitable foliage, were also tastefully arranged by five lady exhibitors, among which Miss Bott, of Brenton; Mrs. Hyde, Maidstone Court Gardens; and Miss E. Bull were successful prize-takers in the order named.

Among trade exhibits, the King's Acre Nursery Company arranged a large stand of wreaths, bouquets, and other floral devices, together with a collection of apples of exceptionally good quality, in upwards of 130 varieties, in baskets and dishes. Messrs. Young and Co. Hatherley, Cheltenham, contributed a large bank of choice tree carnations arranged in vases; and Mr. Wilson, Commercial Street, Hereford, set up a large stand of splendidly arranged floral devices and vases of cut flowers.

Brighton Chrysanthemum Show.

The Brighton and Sussex Society held its autumn exhibition in the Dome and Corn Exchange on October 31 and November 1. The show was an excellent one, but one missed the splendid groups of chrysanthemums that for years were such a fine feature, and there was not the array of flowers on boards that used to be on view. On this occasion several of the vase classes were especially good, and begonias and bush chrysanthemums were well shown, while fruits and vegetables were excellent, and non-competitive displays were of great merit and interest.

Mr. A. J. Gaston, the new secretary, has secured a goodly number of new members during 1911, and his energy and enthusiasm promise to be valuable assets to the society.

CUT FLOWERS.

There were no fewer than seven competitors in the class for thirty-six Japanese blooms, not less than twenty-four varieties. The premier award is a cash prize of 60s. and a silver bowl, presented by the President, Alderman Sir Jeremiah Colman. Leading honours fell to Mr. W. Evans, gardener to Mrs. Stewart Mackenzie, Lyndhurst, Haywards Heath, who staged fine, clean specimens of Hon. Mrs. Lopes, C. H. Totty, Bessie Godfrey, Reginald Vallis, Mrs. A. T. Miller, Sir Frank Crisp, F. S. Vallis, Master David, Eclipse, F. W. Lever, Lady Letchworth, Rose Pockett, Algernon Davis, Lester Morrison, Elsie Miller, Mr. R. H. B. Marsham, and J. Lock. Second prize was awarded to Mr. J. Harris, gardener to Colonel C. P. Henty, J.P., Avisford, Arundel, who had fine flowers not yet fully expanded in many cases; Mr. Chas. Hack, gardener to Mrs. L. C. Joad, Patching, Worthing, third; and Messrs. Jas. Stredwick and Son, Silverhill Park, St. Leonards, fourth.

Mr. C. Fox, an amateur, of Linden Gardens, Tunbridge Wells, gained the silver medal and first prize for twenty-five Japanese blooms, distinct, staged in five vases, each set on a separate table. He had handsome flowers of Reg. Vallis, Lady Crisp, Evangeline, Master David, Mrs. Trevor Williams, Henry Poulton, Shanklin Sunshine, Lady Letchworth, W. P. Walker, Beatrice May, etc.; Messrs. J. Stredwick and Son, second; and Mr. J. E. Hickson, gardener to the Rev. F. S. Sclater, Newick Park, Lewes, third.

The best dozen Japanese, distinct, were from Mr. F. Cordell, and his best blooms were Miss A. Nicoll, Lady Crisp, Rose Pockett, Pres. Viger, and Mrs. R. Linford; Mr. W. J. Finch, gardener to F. A. White, Esq., Oakleigh, East Grinstead, came second, and Mr. J. C. Reeves third. Six incurved blooms, one variety, found Mrs. J. Harris to the front with good examples of Embleme Poitdevine; Mr. A. Sayers, gardener to S. Copestake, Esq., Adelaide Crescent, Hove, second; and Mr. J. C. Reeves, third. Mr. J. C. Reeves led for six Japanese blooms, one variety, any colour, with Mrs. A. T. Miller; Mr. C. Hack second. For six Japanese, distinct, Mr. F. Cordell, gardener to A. F. Blades, Esq., Rookfields, Reigate, scored with Lady Crisp, Miss A. Nicoll, Mrs. R. Linford, Mrs. A. T. Miller, Master James, and Mrs. G. Mileham; Mr. J. Harris second.

Three vases of pompons made a pretty class, and honours fell in order of merit to Mr. G. H. Bennett, Mr. W. G. Pelley, Adavale, Chesswood Road, Worthing; and Mr. J. C. Reeves, gardener to Captain Acton Blake, Rusper. Singles, three vases, was an equally good class, the vases being well filled with fine flowers in great variety; Mr. H. Eastwood, gardener to Dr. Bryant, Tongdean, Dyke Road Avenue, Brighton, led with an exceptionally good set, and was followed by Mr. W. G. Pelley, and Mr. G. Chandler.

Mr. W. Hill, gardener to G. W. Ryder, Esq., Broadhill, Keymer, led for a table of chrysanthemum blooms, arranged artistically with plenty of foliage. He had the finest flowers, and arranged them skilfully, but Mr. Chandler, who was second, might possibly have been first had his pots been less in evidence; Messrs. G. Miles and Son third.

In the amateur classes for cut flowers, the principal prizewinners were Mr. C. Fox, Tunbridge Wells, who won most of the first prizes; and Mr. J. R. Burrows, Preston Park. Mr. G. Fennell, Mount Zion Place, Brighton, led for a group in the amateurs' division with a very creditable display; Mr. E. Farrell, Sandown Road, Brighton, second; and Mr. A. Franks, Roedale Road, Brighton, third.

Messrs. G. Miles and Son, Victoria Nurseries, secured the chief award for a mantelpiece decorated with chrysanthemums, and they used yellow, buff, and orange flowers, with crotons, ferns, and asparagus, and made a very pretty display. For a mantelpiece decorated with any kind of flowers, Mrs. H. J. Brill, Southdown Avenue, Preston Park, led with a design composed chiefly of scarlet carnations and Lilium speciosum. Mrs. Brill was also the leading competitor in the table decoration class with a charming design in golden and pale bronze chrysanthemums and asparagus sprays; Miss S. Cheesman, Islingwood Road, Brighton, second, with pink single flowers; and Mrs. Pelley third with bronze and red single varieties.

GROUPS AND PLANTS.

Only two groups were staged in the chief class for an arrangement staged on a circle 8ft. 6in. in diameter; Mr. G. Chandler, gardener to S. C. Witting, Esq., Hollingbury Copse, Patcham, Brighton, led with a high conical group of Japanese, decorative and single chrysanthemums, with a base of plumose nephrolepises; Mr. G. H. Bennett, gardener to P. H. Bayer, Esq., Hatch Beauchamp, Withdeane, Brighton, was second with a group that lacked something in finish around the base. In another group class, for chrysanthemums only, Mr. A. J. Jones, gardener to E. M. Marx, Esq., Hanover House, Hanover Crescent, Brighton, was the only exhibitor, and he was awarded the first prize. Many of his flowers were not yet at their best, but he had a fair representation, and plenty of bright colours.

In an open class for six bush plants Mr. G. Lambert won first place with dwarf, neat examples, carrying flowers of large size; Mr. Sayers was a very close second, and Mr. G. H. Bennett third. Mr. G. H. Bennett led for a dozen bush plants, pompon varieties, and he set up a useful lot of bushes carrying abundance of blossoms; Mr. G. Lambert second, and Mr. A. Sayers third; very few plants were labelled in this class —a great failing.

Mr. G. H. Bennett scored for six bush chrysanthemums, with large, freely-flowered plants of Mary Richardson, Miss Cressy, Kitty Bourne, Mrs. Willie Jordan, and Ladysmith; Mr. H. Eastwood second, and Mr. S. Watkins, Preston, third.

There were five entries in the class for a dozen dwarf bush plants, pots not to exceed 6in. in diameter. Mr. H. Lelliott, New Church Road Nurseries, Hove, was a good first, with very freely-flowered specimens, some carrying over five dozen flowers; Mr. G. Norman, The Garden House, Upper Drive, Hove, second; and Messrs. G. Miles and Son third.

One table of orchids was staged, and this, from Mr. W. Hill, Keymer, was awarded a first prize; calanthes, Odontoglossum grande, Cattleya labiata, pleiones, and Cypripedium Spicerianum were the chief subjects in the display. Mr. W. Humphery, gardener to F. W. Franks, Esq., Loampits, Tonbridge, was a capital first for nine begonias, and he staged B. Gloire de Lorraine in fine form; Mr. J. E. Hickson second. Primulas were very poorly shown.

FRUITS AND VEGETABLES.

For three bunches of white grapes the premier award fell to Mr. C. Earl, gardener to O. E. D'Avigdor Goldsmid, Esq., Somerhill, Tonbridge, for Muscat of Alexandria, well coloured; Mr. W. Lintott, gardener to Sir Walpole Greenwell, Bart., Marden Park, Caterham, second; and Miss Smith, Miramichi, Withdeane, third. For black grapes, three bunches, Mr. W. Monton, gardener to Mrs. Mashiter, The Grange, Hurstpierpoint, scored with Alicante, Miss Smith coming second, and Mr. C. Earl third; there were nine entries in this class, and five in the white grape class.

The best four dishes of dessert apples came from Mr. J. R. Allan, gardener to C. A. Morris Field, Esq., Ashurst Park, Tunbridge Wells, who showed big fruits of Mère de Ménage, Bramley's Seedling, Warner's King, and Hambling's Seedling; Mr. F. A. Sandalls, gardener to Messrs. Parker and Hind, Rottingdean School, second. Mr. A. G. Clarke, gardener to Dr. Rouse, Farncombe Road, Worthing, had the best single dish of culinary apples, winning with Warner's King. For dessert apples Mr. J. Muddell, gardener to Mrs. Henderson, Sedgwide Park, Horsham, led for four dishes, with Blenheim Pippin, Adam's Pearmain, Cox's Orange Pippin, and Ribston Pippin; Mr. Morton second, and Mr. A. Kemp, Horsham, third. Mr. W. J. Finch, gardener to F. A. White, Esq., Oakleigh, East Grinstead, was a capital first for four dishes of pears, with grand fruits of Durondeau, Beurre Fouqueray, Doyenne du Comice, and Beurre Diel; Mr. Hickson second, and Mr. J. McCulloch, gardener to Lord Cowdray, Paddockhurst, Crawley, third.

In the open class for vegetables, eight kinds, there were five entrants, and the silver medal and first prize fell to Mr. W. J. Finch, for a fine set of Sutton's Exhibition Brussels sprouts, Autumn Giant cauliflowers, Prizetaker leeks, Standard Bearer celery.

BRADFORD CHRYSANTHEMUM EXHIBITION in ST. GEORGE'S HALL. on FRIDAY and SATURDAY, November 10th and 11th.
£50 FOR BLOOMS ON BOARDS.
Besides other good classes for open competition.
Schedules, with entry forms, post free from
H. SPENCER,
Hony. Secy.
Horton Park,
Bradford.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

Ailsa Craig onions, Duchess of Cornwall potatoes, Pragnell's Exhibition beet, and New Red Intermediate carrots; Mr. W. Manton second, and Mr. W. Humphery third.

Mr. R. Moore, New Road, Lewes, and Mr. J. Geall, Lewes Road, were winners in other classes for collections of vegetables. Cauliflowers were finely shown, and so were long beets, onions, celery, and potatoes; Mr. Kemp, Coolhurst Gardens, Horsham, led for four dishes of the latter with a beautiful set of Dalhousie, Satisfaction, Kemp's Foundling, and Recorder, while for one dish of six onions Mr. W. J. Finch won first prize with a splendid set of Ailsa Craig.

NON-COMPETITIVE.

The non-competing exhibits added materially to the interest and extent of the show, and among the notable competitors in this department we may refer to Messrs. W. W. Balchin and Sons, Brighton, who had a delightful arrangement of brilliant crotons, choice ferns, and chrysanthemums. Mr. Neal, gardener to J. A. Nix, Esq., Tilgate, Crawley, presented a splendid collection of apples, pears, and grapes, all finely arranged with ampelopsis leaves and asparagus sprays. Messrs. G. Miles and Son, Victoria Nurseries, sent floral devices. Mr. Frank Woollard, Lewes Road, Brighton, showed roses and hardy fruits. Messrs. W. Wells and Co., Merstham, exhibited single and decorative chrysanthemums in big stands. Messrs. Toogood and Sons, Southampton, staged a very fine collection of vegetables in first-rate style over close cropped newly sown lawn grass. Messrs. Allwood Brothers, Haywards Heath, contributed perpetual carnations in pleasing fashion and in great variety. Mr. G. W. Piper, Uckfield, had an unusually fine exhibit of late-flowering roses, all from the open air; there were probably a hundred varieties represented in this fragrant and beautiful exhibit, an exhibit that was greatly appreciated at the end of October.

Mr. W. J. Burstow, Ravenswood, Worthing, set up a small group of British ferns, in which frilled and tasselled Hart's-tongues were prominent, but the feature of the exhibit was a fine specimen of Polypodium vulgare cambricum, fully a yard across. Messrs. J. Cheal and Sons, Crawley, filled a large table with a handsome collection of apples, the fruits being finely coloured and well arranged; from the Barnham Nurseries Company, Barnham, also came a collection of hardy fruits.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, OCTOBER 24.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair); Dr. A. B. Rendle, F.R.S., Messrs. H. J. Elwes, F.R.S., A. Worsley, W. Hales, J. T. Bennett-Poë, M.A., V.M.H., J. Douglas, V.M.H., R. A. Rolfe, A.L.S., J. O'Brien, V.M.H., G. Wilson, C. H. Hooper, W. Fawcett, B.Sc., J. O'Dell, W. C. Worsdell, G. Gordon, V.M.H., R. Hooper Pearson, and F. J. Chittenden (hon. secretary).

NERINE PUDICA ALBA.—Mr. Worsley showed a white-flowered form of what he regarded as Nerine pudica, a seedling raised by him some time ago. He also showed ripe fruits of the variegated form of Vitis heterophylla.

VARIOUS PLANTS.—Mr. H. J. Elwes drew attention to a flower of Pæonia lutea from a plant (sent out by Messrs. Vilmorin) flowering for the second time this year, but now, unlike the first flowering, holding its flowers well above the foliage. Mr. Bowles remarked that he had a form which normally flowered in this way, also from Messrs. Vilmorin. Mr. Elwes also showed a plant of Statice fruticans (= arborea), a Canary Island species, raised from seed, and flowering well within a year of seed-sowing; Aristea corymbosa, a woody Iridaceous plant from South Africa; and Stapelia primulina.

PRIMULA SINENSIS STELLATA.—A remarkable instance of foliose development of the calyx in Primula sinensis stellata was shown by Mr. Odell, in which the calyx segments were many times as long as the petals, and were of distinct leafy form.

MALFORMATION IN VITIS SICYOIDES.—Mr. W. Patterson sent an interesting specimen of a malformed Vitis sicyoides from St. Vincent. The malformation is mentioned in Grisebach's "Flora of the British West India Islands," where it is said to be common, but this is the first specimen met with by Mr. Patterson. It was growing "just where the conditions prevailing might be expected to exert influence to encourage an inflorescence to grow into such a form, namely, moisture and very little light." The specimen sent, which was over 15in. in length and consisted of long, slender branches bearing numerous short, whorled branchlets was "part of one axillary growth found growing on the ground under dense shade." Mr. Patterson drew attention to dark streaks of fungus spores on the ultimate branches, and suggested that the malformation might be of pathological origin. The fungus present is Shrœteria Cissi (De Toni), a member of the Ustilagineæ, and no doubt the cause of the malformation. The form which it gives rise to has been described as a type of a new genus, Spondylantha aphylla, by Presl [see "Rel. Haenk.," ii., 35, t. 53 (1834)].

CATTLEYA SORORIA, RCHB. F.—Mr. R. A. Rolfe exhibited a flower which had been raised in the collection of W. Evans, Esq., of Leicester, from C. Harrisoniana crossed with the pollen of C. bicolor, and remarked that it was identical with the natural hybrid, C. sororia, Rchb. f., and thus confirmed its supposed parentage, which was originally in doubt. He also exhibited for comparison paintings from the "Dictionnaire des Orchidées" of the two parents, remarking incidentally that the one figured as C. Harrisoniana was wrongly labelled C. Loddigesi, and that, in fact, the names of the two species had been transposed, as was sometimes the case in gardens.

LÆLIO-CATTLEYA AMANDA, RCHB. F. AND L.-C. VERELI, ROLFE.—Mr. Rolfe also exhibited flowers of these two natural hybrids, remarking that they were originally confused under the former name. The first, however, was from Lælia Boothiana and Cattleya intermedia, the latter from L. Boothiana and C. Forbesi, as was evident from the strong red veining on the disc of the lip. All three species were known to grow together in the neighbourhood of Rio de Janeiro. The two hybrids were in flower at Kew, that of L.-c. amanda being from a batch raised by himself by crossing L. Boothiana and C. intermedia, with a view to proving the parentage. Paintings of some of the plants in question were also shown.

POLLINATION IN ORCHARDS.—Mr. C. H. Hooper gave an outline of his observations on pollination in orchards, which confirmed those of others that cross-pollination was necessary in the majority of cases in order that fruit should be produced. The results obtained have been published. Mr. Worsley said that a certain temperature was necessary for the shedding of pollen in many instances, and if this were not attained, infertility might result. Mr. Chittenden said that certain of the varieties Mr. Hooper had found not to set fruit without the aid of foreign pollen, he had found would do so, and suggested that in order to settle the cases, in which only negative evidence was available, it was necessary to repeat the experiment several times, for there was great difficulty in eliminating many other factors which contributed to unfruitfulness.

NATIONAL CHRYSANTHEMUM SOCIETY'S SHOW.

(Continued from page 814.)

From Exmouth Mr. W. J. Godfrey brought up Japanese and single varieties, and set these up well. Practically every variety staged was of his own raising, and they included Captivation, Exmouth Comet, Mrs. R. Ley, and Acquisition among Japanese, and Mrs. F. C. Hunter, Devonshire Cream, Charming, Climax, Miss Mary Pope, and Star of Devon among singles. An exceedingly fine lot of single varieties were set up by Messrs. Cragg, Harrison, and Cragg, of Heston, and their display was the sort of thing that needs encouragement; indeed, we believe the firm put up this group as an object-lesson to competitors; they presented two dozen vases, over ferns, and staged grand blooms of Mensa, Bronze Pagram, Celia, Merstham Jewel, Mrs. W. G. Patching, Roupell Beauty, Mary Richardson, F. King, Snowflake, and Edith Pagram—a charming exhibit of great educational interest.

Mr. H. W. Thorp, Darrington, Worthing, was a large exhibitor, and staged a lot of fine flowers, but the lack of suitable background and of groundwork material militated greatly against the effectiveness of the group. Mr. Frank Brazier, Caterham, presented a considerable group of early and decorative chrysanthemums, Michaelmas daisies, and floral designs. A brilliant bank composed of fine trusses and bunches of splendid zonal pelargoniums and equally attractive single chrysanthemums, arranged in large sprays, was set up by Messrs. H. Cannell and Sons, Swanley, and attracted a great deal of attention.

A table of finely-grown and well-flowered zonal pelargoniums was put up by Mr. W. H. Page, Tangley Nurseries, Hampton. The variety His Majesty, which has already been figured and described in the GARDENERS' MAGAZINE, was in fine form, plants in 48's being furnished with large trusses of brilliant flowers. Winter Cheer and Fiscal Reformer, the latter a clear pink, were also extremely good. Messrs. Wilton and Goddard, Claremont Nurseries, Durrington, near Worthing, arranged an effective group of large-flowered chrysanthemums, among which tall stands of J. Lock, Formality, Mrs. L. Thorn, and others were conspicuous.

A large group of dwarf plants of chrysanthemums, in 48-sized pots, each plant carrying about ten good blooms, was a most attractive exhibit, staged by Messrs. Butler Brothers, Bexley Heath, who are past-masters in the art of producing such plants for the market. Messrs. Stuart Low and Co., Enfield, were represented by a group of carnations and fruits.

Messrs. J. Peed and Son, West Norwood, contributed a large circular group of chrysanthemums, associating cut flowers and plants of chrysanthemums with palms and ferns.

MEDAL AWARDS TO NON-COMPETITIVE EXHIBITS.

Large Gold.—To Mr. H. J. Jones, Lewisham; Mr. Norman Davis, Framfield; Messrs. W. Wells and Co., Merstham; Messrs. Stuart Low and Co., Enfield; Messrs. H. Cannell and Sons, Swanley.

Gold.—Messrs. J. Peed and Son, West Norwood; Mr. P. Ladds, Swanley Junction.

Small Gold.—Messrs. Hobbies, Lim., Dereham; Messrs. H. B. May and Sons, Edmonton; Mr. D. Russell.

Silver-gilt.—Mr. H. W. Thorp, Worthing; Messrs. Butler Brothers, Bexley.

Large Silver Medal.—Messrs. J. Godfrey, Exmouth; Mr. G. H. Godard, Claremont Nursery, Durrington; Messrs. Cragg, Harrison, and Cragg, Heston; Mr. F. Brazier, Caterham; Messrs. W. A. Voss and Co., Millwall; Messrs. J. Cheal and Sons, Crawley.

Small Silver.—Mr. W. H. Page, Tangley Nurseries, Hampton; and Mr. J. Williams, Ealing.

ROYAL HORTICULTURAL INTERNATIONAL EXHIBITION.

We are informed by the Hon. Press Secretary that the Directors of the Royal International Exhibition have agreed:

(1) To give to all Fellows of the Royal Horticultural Society certain special privileges over the general public in regard to the purchase of tickets for the Exhibition; and

(2) To allow all such tickets purchased by Fellows of the Society to be transferable.

ADMISSION ARRANGEMENTS.

GENERAL PUBLIC.

The Directors of the International Horticultural Exhibition have decided on the following prices of admission:

	Before 5 p.m.	5 to 10 p.m.		All day.
May 22	... £2 2 0	£1 1 0	May 27	... 2 6
.. 23	... 1 1 0	10 0	,, 28	... 1 0
.. 24	... 10 0	5 0	,, 29	... 1 0
,, 25	... 5 0	2 6	,, 30	... 1 0

FELLOWS OF THE ROYAL HORTICULTURAL SOCIETY.

The special privileges accorded to Fellows of the R.H.S. are as follows:

Fellows of the R.H.S. paying an annual subscription of four guineas:

May 22.—Two tickets at half-price at either hour.
May 23.—Two tickets at half-price at either hour.
May 24, 25, 27.—Four tickets for any, but only one, of these days; with two additional tickets for the 5s. day—all at half-price.
May 28, 29, 30.—No reduction.

Fellows of the R.H.S. paying an annual subscription of two guineas:

May 22.—One ticket at half-price at either hour.
May 23.—One ticket at half-price at either hour.
May 24. 25, 27.—Two tickets for any, but only one, of these days; with one additional ticket for the 5s. day—all at half-price.
May 28, 29, 30.—No reduction.

Fellows of the R.H.S. paying an annual subscription of one guinea:

May 22.—One ticket at 30s.; or 10s. 6d. after 5 p.m.
May 23, 24, 25, 27.—One ticket at half-price for any, but only one, of these four days.
May 28, 29, 30.—No reduction.

Honorary and corresponding members enjoy the same privileges as two-guinea Fellows.

Associates: May 22, 23, 28, 29, 30, no reduction; one ticket on May 25 or 27 at half price.

One-guinea affiliated societies, May 22, 23, 28, 29, 30, no reduction; ten tickets on May 25 and sixteen tickets on May 27, all at half price. Two-guinea affiliated societies, double privileges.

All privileged tickets on the above scale must be purchased on or before May 12, and can only be obtained direct from the office of the Royal Horticultural Society, Vincent Square, Westminster, S.W.

All the above tickets will be transferable, but will each be available for one admission only. Fellows can, therefore, circulate among their friends such of the tickets as they do not personally require. Cheque or postal order, payable to the Royal Horticultural Society, must accompany each application for tickets, and tickets when once purchased cannot be exchanged for others of a different date.

CATALOGUES RECEIVED.

FREDERICK ROEMER, QUEDLINBURG, GERMANY.—This list of seed novelties for 1912 includes a number of asters that suggest improvements upon many old varieties.

A. F. UPSTONE, Rotherham.—This general autumn catalogue includes bulbs, plants for forcing, roses, fruit trees, shrubs, etc

W. WELLS AND CO., LIM., MERSTHAM, SURREY.—A descriptive list of chrysanthemums, arranged in their various sections, occupies the greater part of this handy catalogue, but perpetual carnations, phloxes, delphiniums, Michaelmas daisies, and herbaceous and alpine plants are also listed.

ARTHUR R. BROWN, LIM., KINGS NORTON.—The little list of border carnations contains descriptions of nine new varieties raised either at the Wychall Nurseries, or by the Rev. C. A. Gottwaltz, of Droitwich.

PHIPPS AND IRELAND, BARNHAM, SUSSEX.—An interesting, descriptive, and instructive little list of alpine and hardy perennial plants.

SEAWEED AS MANURE.

All around the coasts of the British Isles and of other countries in northern Europe seaweed has a high reputation as manure. There is, according to the leaflet issued by the Board of Agriculture, no record nor even any tradition to show when it was first used, or how its value was discovered, but it seems to be essentially a northern manure, and began to be mentioned as soon as descriptions were written of the husbandry of the coast districts.

Where Seaweed is Collected.

Scotland.—In Scotland, the right of gathering seaweed still sometimes forms part of the covenant with the landlord, and has even been the subject of litigation. It appears to be held in special favour on the south-west coast, where there is a good deal of light soil, and cartage presents no particular difficulties; indeed, it is perhaps the chief manure used for early potatoes on the Ayrshire coast, being applied at the rate of 25 to 30 tons per acre in autumn, and then ploughed in. What is gathered in summer is put on top of the "middens" till wanted. Further up the west coast, and also on some of the islands, seaweed is used by the crofters, but it does not appear to be held in so much favour on the east coast, excepting where it can very readily be obtained.

Cornwall and Devon.—Seaweed is still diligently collected in the west country; the amount available is, of course, very variable, and most comes into the bays facing south and south-west—the direction of the storms. In the market gardening regions of South Cornwall it is not, as a rule, used in the fresh condition, but is mixed with sand as of old, and allowed to rot. It is then applied along with guano and superphosphate for early potatoes and cauliflowers. Elsewhere it is put on to the root crops. The material usually collected appears to consist of Fucus serratus, F. vesiculosus, and, after stormy weather, Laminaria digitata. Near some estuaries Ulva lactuca is gathered.

On the North Devon coast seaweed is used for potatoes and roots; so much is it esteemed as a spring dressing that a certain amount is sent by barges to points inland for the use of farmers too far from the sea for cartage to be profitable.

Scilly Isles.—The light soils of the Isles of Scilly are very dependent on a supply of organic matter to retain moisture; as much as fifty tons of seaweed per acre is, therefore, applied for early potatoes, nearly as much for mangolds and other roots, but smaller dressings are put on for corn. A certain amount is also allowed to rot in piles, and is then used for bulb cultivation and general garden purposes. Fucus serratus is most popular, and has the highest reputation, whilst the thick fleshy strands of Laminaria are least esteemed: indeed, it is considered that the latter injure the soil if used too freely. The weed is generally gathered between September and March, and is by far the most important fertiliser in the islands.

Isle of Thanet.—In the Isle of Thanet it is used in several ways. The fresh weed is spread at the rate of ten to fifteen tons per acre over lucerne or sainfoin in the early autumn, and then raked off in spring just before the crop starts. It is also put on the land at the rate of ten to fifteen tons per acre before ploughing, and is found to be very beneficial to such market garden crops as cabbage, celery, asparagus, etc., as well as the ordinary farm crops. Some is also thrown into the dung mixen. It cannot, however, be said to be a very important manure at the present time, and is collected only when other work can be left, the reason probably being that cartage is heavy. A load weighs about a ton, and often requires two horses to get it from the shore; the enormous quantities thrown up by high tides when the wind is from the north or north-east—making a fringe along the high-water mark which may be three or four feet in thickness—sometimes prove more than the market gardeners and farmers on the coast can profitably utilise.

Jersey.—In Jersey not only is the "drift weed" cast up by the tides collected, but seaweed is also cut from the rocks. As much as forty-five tons of the fresh seaweed is applied per acre soon after the crop following early potatoes is out of the way, commonly about the middle of September. Later in the season recourse may be had to seaweed that has been collected, dried, and stacked, this being a regular summer occupation for some of the poorer people of the island. Little, if any, deterioration seems to set in, if the weed is quickly dried and not exposed to rain, while the saving in cartage is considerable. Digging-in takes place in December and January, and planting with early potatoes follows as soon as practicable. From two to four cwt. per acre of a complete artificial manure are usually given in addition.

Other Localities.—Seaweed is largely used on the Irish coast and on the French coast; at Mont St. Michel there is a considerable trade in seaweed as manure. It is also of great importance in some of the New England coast districts.

(To be continued.)

MR. MEASE'S FIRST PRIZE SET OF TWELVE JAPANESE BLOOMS.
This fine set of flowers, in a decorative class at the National Chrysanthemum Society's Exhibition, Crystal Palace, November 1, 2, and 3, was very greatly admired.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

AJUGA BROCKBANKI.—A. L., Hailsham: This by no means common plant is quite hardy, and is equally at home in the front of the border or in the rock garden. It has fairly long spikes of deep blue flowers in June and July. Ajuga genevensis Brockbanki, to give the plant its full title, is of semi-creeping habit, and, though not so aggressive as some hardy perennials, a watchful eye must be kept on it, especially if some small slow growing subject is close to it. There need be no fear as to selection of the right position or soil, as it is a very good-tempered plant, and, though a fair amount of moisture at the roots is appreciated, it does not strongly resent a dry position. Nine inches is its usual height.

JUDGING NEW ROSES.—E. S. M., Cork: The National Rose Society's rules for judging new seedling roses or sports are as follows: 1. The judges to be appointed, on the recommendation of the Exhibitions Committee, by the Council, and to be twelve in number. Five to form a quorum. No award to be made except there be at least a two-thirds majority of those present in favour of any variety. Any judge having an interest in an exhibit shall be asked to retire before the judging of that exhibit begins. 2. Voting to be by a show of hands. The Chairman to have no casting vote. 3. Full particulars of each variety entered to be sent to the Hon. Secretary at least two full days before the show. The points required to be as follows: (1) Name of rose. (2) The class to which it belongs. (3) The habit of growth. (4) The purpose or purposes for which most suitable, whether exhibition, garden, bedding, or otherwise. (5) Whether a seedling or sport. If a sport, the variety from which it came to be given. (6) Whether perpetual-flowering. (7) The raiser's name. (8) The exhibitor's name. (9) The exhibitor to be invited to state the stock on which the ground plant exhibited is worked. 4. That there be three grades of awards, viz., a Gold Medal, a Silver-gilt Medal, and a Card of Commendation. 5. The judging to be in a separate tent or room, and in private. Each exhibit shall be placed separately before the judges on a table provided for the purpose. (Not fewer than six trusses of any new seedling rose or distinct sport have to be shown, and a ground plant of the variety must also be shown.)

GRUBS IN SOIL.—D. G., Stockfield: The grubs in the soil are those of a weevil (Otiorhynchus), a pest quite common in many gardens, especially where leaf soil is abundant and is freely used for pot plants. The weevils are fond of leaf-mould, and often imported with it, hence the necessity in many cases for sterilising the material before use. The pest is sometimes a great trouble in vineries, and when this is the case white sheets should be laid under the vines, and then, after dark, the vines should be smartly tapped and a bright light suddenly flashed upon them. This will cause the little beetle-like weevils to fall, and on the sheets they are quickly detected and disposed of. Where the grubs are found in pot plants they may be killed or evicted by submerging the pots in tepid water for a dozen hours or more, and if the plants are well rooted this treatment will not hurt them. In the case of poorly-rooted or badly damaged plants, little can be done beyond washing the roots quite free from the infested soil, and potting in smaller pots and in light sterilised soil.

THE FINEST MALE FERN.—N. E. B., Salisbury: In all probability lovers of hardy ferns would agree that the finest of the Male ferns is Lastrea filix mas cristata. This is a splendid fern, with fronds four feet long and finely tasselled, and an old specimen will develop quite a trunk like a small tree fern. You cannot do wrong in purchasing several plants of this variety.

KAINIT FOR FRUIT TREES.—B. T., Harlow: Lack of colour and flavour in the fruits is probably due to the need of potash in the soil. To supply the deficiency dress the root area of the trees with kainit at the rate of two ounces per square yard, and lightly hoe it in; the dressing should be given at once.

TALLY OF CABBAGES.—T. D., Grantham: Five dozen cabbages usually go to a tally. A hand of radishes varies according to the season, from a dozen to thirty, and a score of lettuces means twenty-two heads.

TURBAN RANUNCULUSES.—S. T. E., Tunbridge Wells: These attractive flowers may be grown in pots or boxes, but as a rule they are not so great a success grown thus as in the open. Strong selected tubers should be used and placed, claws downwards, from four to six inches apart, and about an inch and a-half deep. Well-drained rich soil, composed of sandy loam, decayed manure, and leaf-soil should be used. Make soil and tubers quite firm. A cold frame will be the best place for the boxes for some time to come, but ventilation must be afforded freely on all favourable occasions. When roots have been freely formed the shelf of a cool greenhouse will provide a suitable position, and when growth is advancing, a warmer greenhouse will help to forward the flowers. Forcing, in the general sense of that expression, should be avoided, or disaster will follow.

LATE DESSERT APPLES.—W. B., Cork: The very best of the dessert apples are over before March, but there are several of passable quality that may be kept until March and April in a suitable fruit room. These include Allen's Everlasting, D'Arcy Spice, Cockle's Pippin, Cornish Gilliflower, Court Pendu Plat, Court of Wick, Duke of Devonshire, Golden Pippin, King of Tompkins County, Lord Burghley, Lord Hindlip, Margil, Northern Spy, Old Nonpareil, Sturmer Pippin. Cockle's Pippin, Duke of Devonshire, and Lord Hindlip make three good late sorts, while Lord Burghley, King of Tompkin's County, Court Pendu Plat, and Sturmer Pippin are all good for use in late winter or very early spring.

NAMES OF PLANTS.

S. S., Bedford.—Physalis Alkekengi.

X Y Z (Hants).—1, Escallonia macrantha; 2, a Cotoneaster, send in flower or fruit.

C. G. N., Teddington.—1, Adiantum peruvianum; 2, Pteris umbrosa; 3, probably Osmunda japonica.

S. G. W., Barrow.—1, Berberis Thunbergi; 2, Selaginella amœna; 3, S. Emileana; 4, Croton aveitense; 5, Pinus cembra.

A. H. P., Melton Mowbray.—1. Cypripedium Leeanum; 2, Odontoglossum ardentissimum; 3, not recognised; 4, Begonia fuchsioides.

A. P., Teignmouth.—1, Pittosporum Tobira; 2, Arundinaria Simoni; 3, Origanum hybridum; 4, Erica mediterranea; 5, Rodgersia podophylla; 6, Lycium barbarum.

NAMES OF FRUIT.

B. B., Bolney.—Evagil.

T. M., Llanelly.—Grenadier.

L. V. B., Henbury.—Blanders.

W. C., Sawmills.—Cornish Crab.

H. A. J., Swindon.—1, Bismarck; 2, Beurre Diel.

J. B., Kingston.—1, Newton Wonder; 2, Fearn's Pippin; 3, Alfriston.

R. D. H., Hitchin.—1, Dumelow's Seedling; 2, Braddick's Nonpareil.

H. W., Farnsfield.—1, Smart's Prince Arthur; 2, Adam's Pearmain; 3, Fearn's Pippin.

C. R., Burton.—1, Lane's Prince Albert; 2, Duchesse d'Angoulême; 3, Bramley's Seedling; 4, Blenheim Pippin.

N. S., Cheltenham.—1, Ecklinville; 2, Warner's King; 3, Golden Noble; 4, not in character; 5, Lady Henniker.

R. S., Littleham.—1, Calville Rouge d'Hiver; 2, Margil; 3, Reinette de Canada; 4, Mabbott's Pearmain; 5 and 6, not recognised.

S., Belvedere.—1, Herefordshire Beefing; 2, Adams' Pearmain; 4, Barcelona Pearmain; 5, Barchard's Seedling Court Pendu Plat; 6, Nonsuch.

F. F., Canterbury.—1, Hambling's Seedling; 2, King of the Pippins; 3, Bismarck; 4, Dutch Mignonne; 5, Doyenne du Comice; 6, Durondeau.

J. H. P. Chilworth.—1, Withington Fillbasket; 2, Hanwell Souring; 3, Herefordshire Pearmain; 4, Hollandbury; 5, Hormead Pearmain; 6, Gravenstein.

G. B., Dublin.—The fruits were not well packed, and as they had shifted in the box with every movement during the journey, a number of the specimens were damaged beyond recognition. Scoring the numbers on the fruits also tends to disfigure the fruits and set up decay. Those identified are: 5, Durondeau; 6 and 8, Beurre Bosc; 7, probably Beurre Hardy.

Woolton Chrysanthemum Show.

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price **10/6.** Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).

NEW BOOK.

REGENT'S PARK AND PRIMROSE HILL.

By A. D. Webster. (Greening and Co., Lim., 91, St. Martin's Lane, London, W.C.). Price 5s. net.

In the preparation of this admirably written book, Mr. A. D. Webster has rendered a service of much value to those who take an intelligent interest in the many fine open spaces to which the general public have access in London. The historical aspects and distinctive features of the numerous parks and gardens that are under the care of the London County Council are fully dealt with in the excellent work written by Lieut.-Colonel Sexby during the period in which he occupied the position of Chief Officer of the London County Council's parks and gardens. But until the present time the Royal Parks and Gardens within the metropolis that are open to the public have not had a work specially devoted to them. Much of their history may be found by diligent research, and some books that have been published will render help; but there is no book that is exclusively devoted to them in which their history and characteristic features are set forth with sufficient fulness of detail to satisfy those who are desirous of becoming well acquainted with their historical associations, and the trees, shrubs, plants, etc., with which they are so richly furnished. Hence the volume relating to Regent's Park and Primrose Hill from Mr. Webster's facile pen is especially welcome.

The author in his opening chapter takes us back to the time when the site of Regent's Park was a portion of an extensive tract of well-wooded pasture land called the Marylebone Park Fields. Marylebone Park dates from the time of Henry VIII., when the Manor House was built, and continued under the Crown until about the middle of the seventeenth century, when it was granted by King Charles to two of his adherents, as a security for a debt due to them for supplying arms and ammunition. After the death of Charles the park was sold by the order of the Parliament, and the price realised was £13,215 6s. 8d. Cromwell converted the park to other uses, the land being let on lease for various periods to different noblemen. The last of the leases to expire was that held by the Duke of Portland, who gave up the land in 1811, shortly after which the formation of the present park was commenced. The park has thus a history extending exactly over a hundred years, and the writing of it affords abundant scope for the display of literary ability of a high order. Mr. Webster has taken full advantage of his opportunity, and has shown that he has a thorough acquaintance with the historical associations of the park, and possesses the ability to present the multiplicity of facts to his readers in an extremely interesting manner.

It is interesting to read in the chapter devoted to the flower garden which occupies an enclosure at the south east corner, that this attractive area was laid out at the direct instigation of the Prince Consort. The flower beds were originally designed by Nesfield, and laid out in 1865; and the mounds on the eastern side of the flower garden, that were formed to relieve the flatness characteristic of this part of the park, were made with soil brought from the reservoir in Tolmer's Square. Reference is made to the handsome vases with which the flower garden is embellished, and it is stated that the Griffon vase, which stands near the fountain, requires about four hundred plants to furnish it properly.

It would be a pleasant task to refer at some length to the majority of the chapters into which the book is divided, but space will not permit. We must therefore be content with advising those of our readers who are interested in Regent's Park to buy the book and make themselves fully conversant with its contents, which are throughout varied, instructive, and entertaining. It is freely illustrated, and the illustrations include reproductions of old engravings that show certain of the features of bygone years, as well as reproductions of photographs showing the present aspect of this famous open space.

RIVERS'

Fruit Trees, Roses,
Vines, Figs, Oranges,
AND
Orchard House Trees.

A LARGE AND SELECT STOCK ALWAYS ON VIEW.

ILLUSTRATED AND DESCRIPTIVE CATALOGUE
POST FREE 3d.

THOMAS RIVERS & SON
Sawbridgeworth, Herts.
STATION: HARLOW, G.E.R.

WOKING PRIZE ROSES.

SPECIALITIES:

Roses for Bedding and Garden Decoration, including 2,000 Lyon Rose, and extra strong climbing varieties for Arches, Pergolas, etc.

New Descriptive Catalogue post free on application.

WM. SPOONER & SON,
Arthur's Bridge Nursery,
Telephone: 138 Nat. WOKING.

PLANTING SEASON.

BY APPOINTMENT.

WM. PAUL & SON, WALTHAM CROSS, Ltd.

Nurseries twelve miles from London; south entrance four minutes' walk from Waltham Cross Station (Great Eastern Railway); west entrance five minutes' walk from Tramway Terminus.

SPECIALITIES:

ROSES in all forms, from open ground and in pots. Roses in pots, both dwarfs and climbers, extra fine this season.

FRUIT TREES, for the Orchard Garden, and Forcing House.

HARDY TREES, for Street, Park, and General Planting.

SHRUBS, Evergreen and Deciduous, for General Planting.

HARDY CLIMBING PLANTS for all purposes.

RHODODENDRONS, CAMELLIAS, AND AZALEAS. Rhododendrons from loam, extra fine this season.

HERBACEOUS PLANTS in great variety.

BULBS AND SEEDS and all Garden Sundries.

PRICE LISTS ON APPLICATION.
Inspection Invited.

Upwards of 1,000 Gold Medals, First Prizes, and other Awards at Leading Exhibitions during the past 50 years.

Sole Postal Address—

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Mendel's Law.

As Mendel's Law has become, so to speak, a household word in the horticultural world, a short description of its real nature, and the incalculable value which a knowledge of it involves to the practical plant and animal breeder, may not be out of place. Until this law was demonstrated all breeding, or cross-breeding, was effected, to a large extent, in the dark, was that the peculiarities of and although the general rule the parent might reasonably be expected to reappear in the progeny, what would happen if parents of different species or varieties were employed could only be guessed at beforehand, and what did result was often of an extraordinary character. One perplexing feature in particular was the fact that very often when crosses were attempted, although the greatest care was exercised, no apparently successful result was obtained, the progeny exactly resembling one parent only, thus being either rejected or mingled with the common herd again as ordinary seedlings or offspring. Abbé Gregor Mendel, in charge of a monastery in Brunn, conceived, however, the idea that, despite the incomprehensible and puzzling results of cross-breeding, they must be governed by some settled law, and, therefore, in the fifties of the last century he set himself to work to find it out. In order to do so he started his experiments on the simplest lines he could conceive, by selecting the various forms of the edible pea on the following grounds: Firstly, the flowers of these are so constructed that from the outset their anthers and stigmas are protected from outside pollen (which, of course, would produce unwished-for crosses) by being tightly enveloped in what is termed the keel or underpart of the flower, and by opening this keel before the flower was fully grown, he could extract his own unripe pollen-bearing anthers and insert instead the ripe pollen he desired to use, thus ensuring the desired cross. Secondly, these peas show very definite and distinct characters, such as differently coloured flowers, and very differently coloured and shaped peas, as well as pods. Finally, as they are annuals, he could get a fresh generation every year for the purpose of studying and tabulating results, and starting fresh experiments. From these experiments he speedily hit upon a very singular fact, viz., that the marked characters aforesaid were definite indissoluble "things," so to speak, and that these "things" fell into two distinct categories, some being peculiarly assertive, "dominant," and the others less so, "recessive." The next discovery was that in a cross involving a dominant character and a recessive one, all the offspring resembled the dominant one, so that, apparently, the recessive parent had failed altogether to act, even though it was the recessive parent which bore the seed, for the same result occurred whichever was the seed bearer. These first family "dominants" being self-fertilised, the next remarkable result transpired that from their seed arose two kinds of plants, viz., "dominant" and "recessive," like the grandparents, but always in the proportion of three dominants to one recessive when the average of a large number was taken. Here then was an obvious law, and a long series of crossings and intercrossings proved that the characters, "dominant" or "recessive," never intermingled absolutely, but only temporarily; so that when another period of reproduction occurred they were capable of dissociation or segregation, and, thus dissociated, of asserting their different potencies in the ratio named. It may, therefore, roughly be put that every dominant character possessed threefold power over the recessive by producing three times as many reproductive gemmules. The next important thing proved was that, in order to obtain permanently pure strains of either kind, it was only necessary to fertilise recessive with recessive or dominant with dominant, and the other character was so entirely eliminated that it bred thereafter perfectly true. This, for the plant breeder, was in itself an invaluable discovery, since without this knowledge it often took years to establish a really reliable strain, since the mere elimination of "rogues" only purified to a small extent, because some apparently true ones still retained the potencies of the other ancestor latent in their system. Unfortunately for the world, these results of the Abbé's researches, extending over eight years, and embracing an immense number of experiments, all of which proved the law to exist, were practically buried for five-and-thirty years among the records of a local natural history society in Brunn; and consequently only really saw the light in 1900, when Professor Hugo de Vries, who was independently pursuing the same line of research, came across the paper, and gave it to the world at large. Its importance being at once recognised, it formed the basis of experiment in innumerable hands, both botanical and zoological, and was found to be equally applicable to animals as to plants. The same ratios of "dominant" and "recessive" came out in all cases where sufficiently distinct characters presented themselves; and, above all, the same "dominant" prevalence in the first family was found to assert itself; so that the breeder, instead of rejecting its members as failures, now knows that in them he has probably precisely the cross he desires, and has only to cross them again to obtain it in the succeeding family, in the ratio of 3 to 1. Furthermore, as with the seedsman, he now knows exactly how to proceed in order to obtain a pure and constant strain on systematic lines. To those who may desire to pursue experiments on Mendelian lines, it is advisable to point out that it is only by doing so to a fairly large extent that

MR. F. JENNINGS.

this ratio becomes clear by averaging the results. The principle underlying the predominance of the dominant characters over the recessive in the results obtained has been compared to that shown by mixing up intimately a large number of black and white shots in a bowl, three black and one white, and employing a blind man to pick out four at a time; the law of chance will then determine that the groups of four will average out to three blacks to one white. The threefold pre-eminence of the dominants in the results of crossing is thus seen to be a mathematical necessity of their original threefold numerical power. The most curious feature in the discovery is therefore this definite triplication of one character over another with apparently no deviation either among plants or animals.

Mr. F. Jennings, whose portrait we have the pleasure of giving in this issue, may well be described as "a worthy son of worthy sire," for, possessing horticultural instincts of a high order, he has, by means of his remarkable energy, unremitting attention to the multifarious details of garden management, and great natural ability, attained to one of the highest positions to which the practical horticulturist can rise in this country. Mr. Jennings, who has had charge of the magnificent gardens of Chatsworth, the world-renowned seat of the Duke of Devonshire, during the past five years, is a son of Mr. Jennings, the chief of the gardens at Ascott, the seat of Lionel de Rothschild, Esq., who is properly recognised as one of the foremost gardeners of his day, and has evidently inherited much of his father's ability. Like many other able men in various walks of life, Mr. Jennings is somewhat reticent as to his work, and prefers that it should speak for itself. This it does in such manner as to convince those who have an opportunity of visiting the gardens of Chatsworth, and are in a position to appreciate the excellence of what is being done within their boundaries, that Mr. Jennings is proving in every way a worthy successor to such eminent horticulturists as Sir Joseph Paxton, Mr. Thomas Speed, and Mr. Owen Thomas, V.M.H. That Mr. Jennings received a thorough training in gardens of the first class previous to undertaking the responsible duties associated with the position he now occupies goes without saying, but it may be mentioned, as a point of some interest, that among the gardens in which he occupied a prominent position were those of Rangemore and West Dean Park.

Burton Flower Show, which was held in the course of the past summer, was remarkably successful from a horticultural point of view, but the financial results were far from satisfactory. At a meeting of the committee, held at the Burton Town Hall, Mr. A. Fox, the secretary, presented to the members of the committee a statement of payments and receipts which had been passed by the Finance Committee, but from lack of time had not been finally checked. This showed receipts amounting to £752 4s. 4d., and payments amounting to £751 1s. 9d., leaving a balance of £1 2s. 7d., as compared with one of £122 18s. 10d. last year. The falling off in the receipts was attributed to an alteration in the date, the Foresters' fête, a trotting match, the railway strike, and the Coronation. No blame appears to have been attached to the weather, which may have been bright and warm. It is possible that the great heat had a deterrent effect on visitors, as in the case of many other flower shows that were held during the past summer.

Forestry and Ornamental Trees.—For the purpose of meeting the ever-increasing demand for trustworthy information on the various aspects of forestry and on ornamental trees and shrubs, we shall devote our next issue (November 18) chiefly to forestry, hedge-row timber, and trees and shrubs specially adapted for the ornamentation of gardens. The principal contributions will include "Scottish and German Methods of Forestry," "Profitable Woodlands," "Hedgerow Timber," "Specimen Trees for Parks and Gardens," "Evergreen Hedges," "Trees for Small Gardens," "Flowering Shrubs as Lawn Specimens," "Shrubby Climbers," and "Grouping Trees and Shrubs." The whole of the articles are contributed by authorities of the highest eminence, and the majority will be freely illustrated. The issue will be of quite exceptional interest, and we strongly advise those of our readers who require additional copies to give their orders well in advance.

Mr. Thomas Stevenson's Successes in Paris.—Our readers will be interested to know that Mr. Thomas Stevenson was the only English exhibitor of chrysanthemums at the Paris Autumn Show, which opened on the 3rd inst. His group, which occupied the most prominent place in the show, just facing the chief entrance, was a splendid triumph of artistic arrangement and cultural skill. The French amateurs and gardeners were in ecstacies over the group, there being nothing like it in the show. Mr. Stevenson entered in five classes, and was awarded a Work of Art, three gold medals, and a large silver-gilt medal.

October in the North.—The weather during October, writes our Aberdeen correspondent, remained wonderfully good. There were thirteen days on which rain fell in measurable quantities, the whole fall amounting to about 2½ inches. The average rainfall in the north for this month during the past forty years, ending with and including 1910, is fully three inches (3.31), the largest quantity for an October being nearly seven inches (6.87) in 1895, and the smallest fully an inch (1.09), in October, 1899. October is here the month in which we have most rain, on an average, judging from the records of the past forty years, but it does not differ much from August, November, and December, which, along with July, seem to be our rainiest months. In the month under review, from the 5th to the 19th was wholly dry, and very little interference with work or play was experienced during the other fortnight. During the closing week of the month the barometer was low and unsteady, but rose rapidly upon the 27th. Till then the weather was very cold, even for the season, and nearly 11 degrees of frost were registered on the ground surface on the morning of the 28th. The open weather has allowed field work to be steadily prosecuted, and the husbandman has now matters pretty well in hand. The early harvest and the fine weather allowed the winding up of details and the lifting of the potato crop to be all comfortably finished, and matters made cosy for the winter. The only "fly in the ointment" is the unsatisfactory turnip crop, otherwise the outlook is very favourable indeed.

Fig Culture in Pots.—At the afternoon meeting held by the Royal Horticultural Society on Tuesday last Mr. James Hudson, V.M.H., gave a lecture at once interesting and instructive on the cultivation of figs in pots. It is so short a time since Mr. Hudson contributed to these pages an article describing the method by which he obtains such splendid results in the cultivation of these luscious fruits in pots, that there is no occasion to refer to the cultural details so ably set forth and highly appreciated by the audience. The lecture was illustrated by a large collection of trees, the majority consisting of bushes ranging from three to four feet in diameter, which were raised from cuttings that were rooted in January and February of the current year. They had been in bearing for some time past, and were carrying large numbers of fruits in various stages of development. Mr. Hudson exhibited ripe fruits of varieties that had been selected for the purpose of showing the finest of the figs for growing in pots, and also to show those that should be avoided. Among the latter were fruits of a variety which Mr. Hudson had found growing alongside the Appian Way when on a visit to Rome a few years since. The fruits are small, bright yellow, and utterly worthless for the table.

English Exhibitors Abroad.—It is not often we find our countrymen exhibiting in France. At the recent Paris Show, however, Messrs. Stuart Low and Co. staged carnations, a nice little batch in vases occupying a prominent position, and for which they received a well-deserved award. In the Orchid Room we also noticed a collection of Cypripedium labiata from Mr. Edward V. Low. We hope in our next issue to give a report of the Paris Show, pressure on our space preventing us from doing so this week.

A New School of Horticulture.—Under the ambitious title of "Imperial School of British Horticulture" a new school of gardening has been founded at West Hampstead for "the purpose of giving instruction and advice to ladies and gentlemen who are interested in gardening, either in their own private grounds, by practical work in classes, by lectures, demonstrations, or a correspondence course." A garden is ready to hand for the work, and a range of glass houses has been obtained, so that practical instruction both in indoor and outdoor gardening can be given to students. Mr. E. F. Hawes, for thirteen years in charge of the Royal Botanic Society's Gardens, Regent's Park, and instructor of the students there during that period, is the principal of the new venture, and his address is Ulysses, Fortune Green, N.W. Mr. Hawes was awarded the Royal Botanic Society's large gold medal, just previous to his recent retirement, in recognition of his services, and we believe this is the first time such an honour has ever been conferred upon an officer of the Society. We shall watch the new venture with considerable interest.

National Chrysanthemum Society.—This society will hold a conference at Carr's Restaurant (Dickens Room), 264, Strand, W.C., on Monday, December 4, 1911, commencing at 7 p.m. Sir Albert Rollit, D.C.L., LL.D., president of the society, will preside. The following papers will be read: (1), at 7 p.m., "The Culture of Disbudded and Spray Blooms," by Mr. F. W. Ladds, to be followed by a discussion; (2), at 8 p.m., "Soil Preparation, and the Use of Some Chemical Foods," by Mr. P. A. Cragg, to be followed by a discussion. All members of the society are cordially invited to attend and take part in the proceedings, and the Committee will also be particularly glad to welcome members of affiliated societies. Members of the public will be admitted on presentation of visiting cards. The conference is being held at Carr's Restaurant, and not at Essex Hall, as marked on the members' passes.

London Window Gardens.—At a meeting of the Metropolitan Public Gardens Association it was decided to continue the promotion of outside window garden competitions during 1912 for prizes presented by the Association, owing to the marked effect which such gardens have in brightening the aspect of poor and monotonous streets, and to include therein gardens composed of bulbs making a show in the spring.

Mr. J. Aplin, who for the past thirty-three years has been head gardener at Hasfield Court, Gloucester, is retiring, we regret to say, owing to ill-health, from the position he has worthily occupied for so long a period. Mr. Aplin, in the course of his activities, gave evidence of a thorough acquaintance with all departments of the garden, and especially distinguished himself as a cultivator and exhibitor of chrysanthemums. Mr. Aplin was for many years a frequent contributor to these pages.

The "Royal" Show at Doncaster.—At the monthly meeting of the Council of the Royal Agricultural Society, Sir Gilbert Greenall reported that certain classes would be added to the schedule of the horticultural exhibition for next year's show at Doncaster, and the exhibition would open on Wednesday, July 3, and close on Saturday, July 6. The society's gold medal would be awarded for a monograph or essay giving evidence of original research, and candidates must reside in Great Britain or Ireland, and must not be either over the age of twenty-seven years or of more than five years' standing from the time of taking their first agricultural qualification, being (a) a degree or diploma of a University or University College, or (b) the national diploma in agriculture.

Second Flowering of Trees, etc.—During October a number of letters were sent to the newspapers with reference to the production of a few blossoms by trees, etc., that usually flower during the spring. The writers appear to have been under the impression that this second flowering is a quite exceptional occurrence, whereas not a year passes without flowers being seen on some of the fruit trees in an orchard. The flowering of trees a second time is somewhat influenced by climatic conditions, and in autumns that follow a dry, hot summer, flower production is more abundant than in seasons of a quite normal character. In turning to the "Times" of October 24, 1811, we find that the second flowering of trees obtained attention one hundred years ago. We read that: "Owing to the unusual continuance of warm weather, many gardens are decorated with blossoms and new-formed flowers, as if it were May." We also read that: "The garden of Mr. Woodward, of Highland, near Uckfield, on Saturday produced a bouquet consisting of laburnum, pea, bean, apple, raspberry, and strawberry blossoms in the highest state of perfection."

Lyndhurst Gardeners' Association has just completed the first year of its activities, and as the result of the success achieved the committee were able to submit a satisfactory report to the members assembled at the annual meeting. There are now nine honorary members and forty-four ordinary members, and the average attendance at the meetings was thirty. The financial results were also satisfactory; with so excellent a report of the year, it is not surprising the officers and members of committee were re-elected.

ROYAL HORTICULTURAL SOCIETY.

On November 7 the Royal Horticultural Hall was by no means well filled with exhibits, but there was an abundance of good material on view, and a fairly good number of novelties. The chrysanthemums and orchids provided a handsome display of bright colouring, and formed the bulk of the show, and the groups of orchids, placed opposite each other down one of the pathways, made an avenue of great floral beauty. The floral studies on view added to the interest of an exhibition that was well attended.

BEGONIA EXQUISITE.

A beautiful new winter-flowering begonia, bearing a profusion of large pink flowers, exquisitely shaded with bright carmine. A.M., R.H.S., November 7. Messrs. Jas. Veitch and Sons, Chelsea.

FLORAL COMMITTEE.

A remarkably brilliant group of winter-flowering begonias, from Messrs. James Veitch and Sons, Chelsea, once more demonstrated the great value of these flowers for the late autumn and winter. The plants, chiefly in 32-sized pots, were smothered in flowers, and these of carmine colour, as in Mrs. Heal, shone grandly under the November sunshine. Some new seedlings of great promise, shown for the first time were Acquisition (A.M.), a large flowered flesh pink variety; Her Majesty (A.M.), the first of the series to show yellow colouring, this shade being suffused with pink so as to produce an apricot tint; and Exquisite (A.M.), a large pink variety, the flowers beautifully shaded with carmine towards the tips of the segments.

The largest, and in many respects the finest, exhibit on this occasion was a splendid one of dwarf, bush specimens of chrysanthemums, grown in 48-sized pots, from Messrs. James Veitch and Sons, Chelsea; there was but one plant in each pot, produced from cuttings struck in March, and pinched four or five times to induce a number of dwarf growths. Each stem, in the case of the decorative sorts, carried one good bloom, and every plant carried a total of from twenty to twenty-eight of these fine flowers. A finer exhibit of cultural skill, or of splendid, useful material suitable for any garden, greenhouse, or conservatory it is not possible to conceive. The varieties were represented by about a dozen specimens of each, and among double decorative sorts those of special merit were Caprice du Printemps, Yellow Cap (A.M.), White Cap, Red Cap, Purple Cap, Dazzler, Felton's Favourite, Greening's Caprice, and Kathleen Thompson; among singles the best, similarly grown, but not disbudded, were Ladysmith, Mary Richardson, Miss Mary Pope, Exmouth Yellow, Elsie Hill, Alice Crate, Countess of Egmont (beautiful golden-bronze), and Lillie Godfrey.

Carnations were extensively shown by Messrs. S. Low and Co., Enfield, and in a very interesting set a few of the best varieties were Lady Alington, Enchantress, Baroness de Brienen (A.M.), a lovely fringed pink; Beacon, Perfection, Gloriosa, and Scarlet Glow.

Single chrysanthemums in great variety, and a collection of nerines, from Mr. Frank Lilley, Guernsey, attracted a good deal of attention; among the latter we noticed N.

Manselli, N. Bowdeni, N. Fothergilli, N. flexuosa alba, and the little white N. pudica.

Messrs. Price and Fyfe, Grove Park Nursery, Lee, put up a group of chrysanthemums, setting up representatives of the various sections in vases, associated with asparagus and autumn foliage.

Mr. Vincent Slade, Taunton, contributed a small collection of cut pelargoniums, the blooms very bright and attractive; and Mr. G. Reuthe, Keston, showed nerines in variety. The old chrysanthemums, Source d'Or and Lizzie Adcock, were displayed in large vases by Mr. G. T. Tubb, New Eltham.

Mr. A. Kingsmill, The Holt, Harrow Weald, sent up great sprays of pernettyas, crowded with berries, and also long trails of Vitis heterophylla, bearing numerous clusters of bluish fruits.

Chrysanthemum Percy Arnold (A.M.), a shapely, decorative single variety, deep and bright rose, with white zone round the disc, came from Mr. J. Longwood, gardener to W. G. Ridger, Esq., Englefield Green.

Messrs. W. Wells and Co., Merstham, had many fine chrysanthemums on view, and their singles, named Merstham Gem, Leo, Polly Duncan, Mensa, Mrs. R. C. Pulling, and Ceddie Mason, were very beautiful. Yellow Cap (A.M.), a yellow decorative; Mrs. Andrew Walker (A.M.), a red bronze reflexed Japanese variety; and Golden King (A.M.), a big yellow incurved, were other good things in a large bright, and bold display.

Mr. P. Ladds, Swanley, displayed Snowflake (A.M.), a large white single chrysanthemum.

In the group from Messrs. W. Cutbush and Son, Highgate, the chief attractions were winter-flowering begonias, heaths, dracænas, and the dwarf polyantha roses, Jessie and Mrs. W. H. Cutbush.

Begonia Gloire de Lorraine, B. Agatha, B. Turnford Hall, and B. Mrs. L. de Rothschild were all well represented by Messrs. H. B. May and Sons, Edmonton; these flowering subjects were set among choice ferns.

A pretty corner group, well arranged by Mr. T. Heron, gardener to H. B. Brandt, Esq., Capenon, Nutfield, was composed of tall stands of big exhibition blooms of Japanese chrysanthemums, and smaller stands and vases of decorative and single varieties, grouped with brilliant crotons and large sprays of autumn-tinted sweet chestnut and beech foliage. It was a very handsome exhibit, and one that was greatly admired.

Another large and bright exhibit of chrysanthemums was the one arranged by Messrs. J. Peed and Sons, West Norwood, and here the stands of Altrincham Yellow, Mensa, George Mileham, Doreen, Mrs. W. Iggulden, Roupell Beauty, and Mrs. J. Peed were outstanding features.

Miss M. W. Anson, Broadway, Streatham, had several dozen paintings of seedling caladium leaves on view; these were remarkably fine, and each under its sheet of glass looked like the real thing. Mr. Frank Galsworthy, Chertsey, submitted floral studies, chiefly of rhododendrons and tulips.

ORCHID COMMITTEE.

Messrs. Cypher and Sons, Cheltenham, presented a very interesting collection of orchids in which cypripediums were very much in evidence, notably C. insigne Harefield Hall, C. Germaine Opoix, C. Niobe, and the fine C. Gaston Bulteel var. King Edward VII. The white form of Lycaste Skinneri and the albino of Oncidium ornithorhynchum were on view, with a specimen of the showy Phaiocymbidium.

Mr. H. J. Chapman, gardener to Mrs. Norman Cookson, Oakwood, Wylam-on-Tyne, sent some beautiful new orchids, and Calanthe Cooksoniæ, a fine white form from C. Harrisi crossed with C. vistita oculata gigantea (F.C.C.), C. Angela, rich ruby red; and Cypripedium Sibyl superbum—C. Francisca crossed with C. Fairrieanum—(A.M.) were among the best.

Messrs. Hassall and Co., Southgate, exhibited Cattleya Minucia, C. Fabia, C. labiata, white and coloured forms, Cypripedium Thalia var. Mrs. F. Wellesley, and Dendrobium Cœlogyne.

A remarkable plant was Odonto-cidium Fowlerianum, the first cross between an odontoglossum and an oncidium, the parents being O. cirrhosum and O. Forbesi respectively; this, shown by J. Gurney Fowler, Esq., Glebelands, South Woodford, has buff sepals and petals, barred and blotched with rich brown, and a yellow lip, marked with red-brown. A Certificate of Appreciation was deservedly awarded.

Messrs. Armstrong and Brown, Tunbridge Wells, showed Cypripedium insigne Gladys, C. Dreadnought, C. Elatior, C. Actæus Bianca, and a fine spike of Odontoglossum Harryano-crispum.

The little group from Mr. Edward V. Low, Vale Bridge, Haywards Heath, contained fine plants of Cattleya labiata W. R. Lee, and C. labiata G. G. Whitelegge, both white forms; Cypripedium Gaston Bulteel was also good in this set of orchids.

Mr. F. Jennings, gardener to the Duke of Devonshire, Chatsworth, exhibited the brilliant Renanthera coccinea, carrying a large, branching inflorescence. Mr. W. Miller, Wisbech; Sir Jeremiah Colman, Reigate; and Mr. C. J. Lucas, Horsham, all showed a few orchids.

Mr. A. Young, gardener to E. R. Ashton, Esq., Camden Road, Tunbridge Wells, put up a large and effective exhibit, wherein the leading subjects were Cattleya labiata, C. Fabia, C. Luegæ, Brasso-cattleya Leemanniæ, and B.-c. Maronæ.

Among the orchids staged effectively by Messrs. Stuart Low and Co., Enfield, we noticed Vanda cœrulea, V. Kimballiana, Cycnoches chlorochilon, Cattleya labiata, Miltonia Roezli alba, and Oncidium Lanceanum.

Mr. W. H. Page, gardener to G. F. Moore, Esq., Chardwar, Bourton-on-the-Water, contributed a charming display of orchids, that owed its elegance chiefly to the dozens of graceful spikes of Dendrobium Phalænopsis Schroderianum associated with sprays of golden oncidiums. Under these were Lælia pumila, Cypripedium Maudiæ, C. insigne varieties, etc., etc.—a very attractive exhibit.

From Messrs. Charlesworth and Co., Haywards Heath, came a small group of orchids, and here the prominent features were Cattleya Fabia, C. Phrygia, Vanda cœrulea in fine form, Odontioda Bohnhofiæ, cypripediums in variety, Zygopetalum Sanderianum, Stanhopea convoluta, and the graceful Liparis Grossi.

In the group from Messrs. J. and A. McBean, Cooksbridge, Cattleya suavior alba was very charming, and Cattleya Venus lutescens (A.M.) was very handsome with its yellow and crimson-purple colouring. Other good things were Cypripedium insigne Sanderæ, with fifteen beautiful blooms, Odontioda Charlesworthi, and Cattleya Fabia.

Messrs. Sander and Sons, St. Albans, were represented by Dendrobium Phalænopsis Schroderianum, D. formosum giganteum, Cypripedium insigne Sanderæ, Cattleya Fabia, C. Ashtoni alba (F.C.C.), a lovely white form with yellow-throated lip, the lovely Dendrobium Sanderæ, etc.

FRUIT COMMITTEE.

Messrs. S. Low and Co., Enfield, set up a small collection of apples.

SCIENTIFIC COMMITTEE.

OCTOMERIA SP. — A finely - flowered plant of Octomeria sp., shown under the name of Baueri, came from Sir Trevor Lawrence. It was taken by Dr. Rendle for examination.

VEGETABLE MARROW FASCIATED.—A well-marked example of this common malformation was sent by Mr. W. A. Voss, particularly remarkable on account of the flowers being produced in pairs along the stem, each pair consisting of either two staminate or two pistillate flowers, and the fruits also growing in pairs.

BITTER-PIT IN APPLES.—Among the numerous diseased plants sent for examination were several specimens of apples attacked by "bitter-pit." This disease is particularly prevalent, even among hard-fleshed apples, this season. It is characterised by numerous brown spots in the flesh at varying depths below the surface, and having, as a rule, no connection with surface injury in any way. No fungi or bacteria have been found connected with it, and it appears to be a disease of physiological origin rather than due to any parasite. The dead, brown cells contain starch, whereas in the rest of the flesh the starch has been converted into sugar. It would, therefore, appear that the death of the cells probably took place before the ripening process had proceeded so far as the conversion of starch into sugar, and may possibly be due to an accumulation of a poisonous substance in the cells through interference with the water supply.

CERTIFICATES AND AWARDS.

First-class Certificate.—To Calanthe Cooksonæ, from Mrs. Norman Cookson (gardener, Mr. H. J. Chapman), Oakwood, Wylam-on-Tyne; to Cattleya Ashtoni alba, from Messrs. Sander and Sons, St. Albans.

Certificate of Appreciation.—To Odontocidium Fowlerianum, from J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), Glebelands, South Woodford.

Award of Merit.—To Cypripedium Sybil superbum, from Mrs. Norman Cookson; to Cattleya Venus lutescens, from Messrs. J. and A. McBean, Cooksbridge; to Chrysanthemums Mrs. Andrew Walker and Golden King, from Messrs. W. Wells and Co., Merstham; to decorative Chrysanthemum Yellow Cap, from Messrs. W. Wells and Co., and Messrs. J. Veitch and Sons, Chelsea; to single Chrysanthemum Percy Arnold, from Mr. W. G. Rigden, Englefield Green; to single Chrysanthemum Snowflake, from Mr. P. Ladds, Swanley; to Perpetual Carnation Baroness de Brienen, from Messrs. Stuart Low and Co., Enfield; and to winter-flowering Begonias Acquisition, Exquisite, and Her Majesty, from Messrs. J. Veitch and Sons, Chelsea.

MEDALS.

Gold.—To Messrs. J. Veitch and Sons, Chelsea, for begonias and chrysanthemums.

Silver Flora.—To Mr. Heron, gardener to H. B. Brandt, Esq., Nutfield, for chrysanthemums; to Messrs. Stuart Low and Co., Enfield, for chrysanthemums; to Messrs. H. B. May and Sons, Edmonton, for begonias and ferns; to Messrs. W. Wells and Co., Merstham, for chrysanthemums; to Messrs. Cypher and Sons, Cheltenham, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. Charlesworth and Co., St. Albans, for orchids; to Mr. A. Young, gardener to E. R. Ashton, Esq., Tunbridge Wells, for orchids.

Silver Banksian.—To Messrs. J. and A. McBean, Cooksbridge, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Mr. Page, gardener to G. F. Moore, Esq., Chardwar, Bourton-on-the-Water, for orchids; to Messrs. Hassell and Co., Southgate, for orchids; to Messrs. Carter Page and Co., London Wall, for chrysanthemums; to Messrs. W. Cutbush and Son, Highgate, for chrysanthemums; to Messrs. J. Peed and Son, West Norwood, for chrysanthemums; and to Miss W. Anson, Streatham, for paintings.

Bronze Flora.—To Mr. L. R. Russell, Richmond, for berried shrubs.

Important to Secretaries of Horticultural Societies. — The edition of the "Gardening Year Book" for 1912 is in an advanced stage of preparation, and secretaries of botanical and horticultural societies and gardeners' associations are earnestly requested to return the notices properly corrected which they have received, with as little delay as possible, so that any changes which have been made in the names or addresses of the secretaries may be duly recorded in the list of Horticultural and Botanical Societies of the United Kingdom. We shall also be glad to receive from our readers notification of any such changes as have come under their notice.

A FINE VASE OF CHRYSANTHEMUMS.

The decorative value of the chrysanthemum must always stand before mere exhibition value, though the line between the two is a very fine one. At the leading autumn shows a larger place is now given to the display of flowers than was formerly the case, and this is all so much to the good, especially where the classes and prizes are so planned that high cultivation, as well as skill in arrangement, are duly rewarded. In a class for a large vase of decorative chrysanthemums at the National Chrysanthemum Society's Show at the Crystal Palace, on November 1, 2, and 3, Mr. A. Dyer, gardener to E. Wood, Esq., The Tyrol, Church Road, Upper Norwood, staged a splendid vase of blooms, and he did not confine his attention to the medium-sized varieties and flowers so generally classed as "decorative," but used excellent white incurved blooms of large size, some Japanese varieties, and a good set of well-developed blooms of single varieties. A little more length of stem in the case of the incurved blooms would have been an advantage, otherwise the exhibit could not be adversely criticised. More bold exhibits of this character, and also on the lines of the great vase of single flowers, so well displayed by Mr. Mills, gardener to F. Lloyd, Esq., Coombe House, Croydon, would add greatly to the beauty and interest of any autumn exhibition.

CARNATIONS BY THE SEA.

In the Gardeners' Magazine of October 28, "G. B." remarks upon the impossibility of growing carnations for more than two or three years without layering, in a certain sea-side garden. Why anyone should desire to retain plants of this age I cannot understand, as I have always had the most satisfactory results from stocks layered each season. It is always more difficult to keep old carnations in health than young selected plants from layers, and, furthermore, one obtains more uniform results and finer blossoms by giving due attention to layering and selection.

For a sea-side garden, especially one so low-lying, this yearly practice of layering should be rigidly adhered to. And, furthermore, one should keep a close watch for all traces of disease, and select for planting the most robust and stout layers. Every means should be used to keep the soil sweet and aerated, and manures or stimulants should be chosen carefully, as upon these and a few other points depends the success or failure of the cultures. I do not claim to have marshy land for carnation culture, but would just like to note a few points of recent notice. Our carnations are, roughly speaking, grown at a distance of one hundred yards from the sea, with a cold easterly exposure. Soil is heavy loam, resting upon a dead retentive clay-bed, which naturally has a deterrent effect upon plant growth. The method of procedure is to break up the soil to the clay bed, also the surface of the clay, taking care not to bring it to the surface. Plenty of sand, wood ashes, and, if possible, mortar rubble, are worked into the soil, also a light dressing of decayed manure, and the whole thoroughly worked into condition.

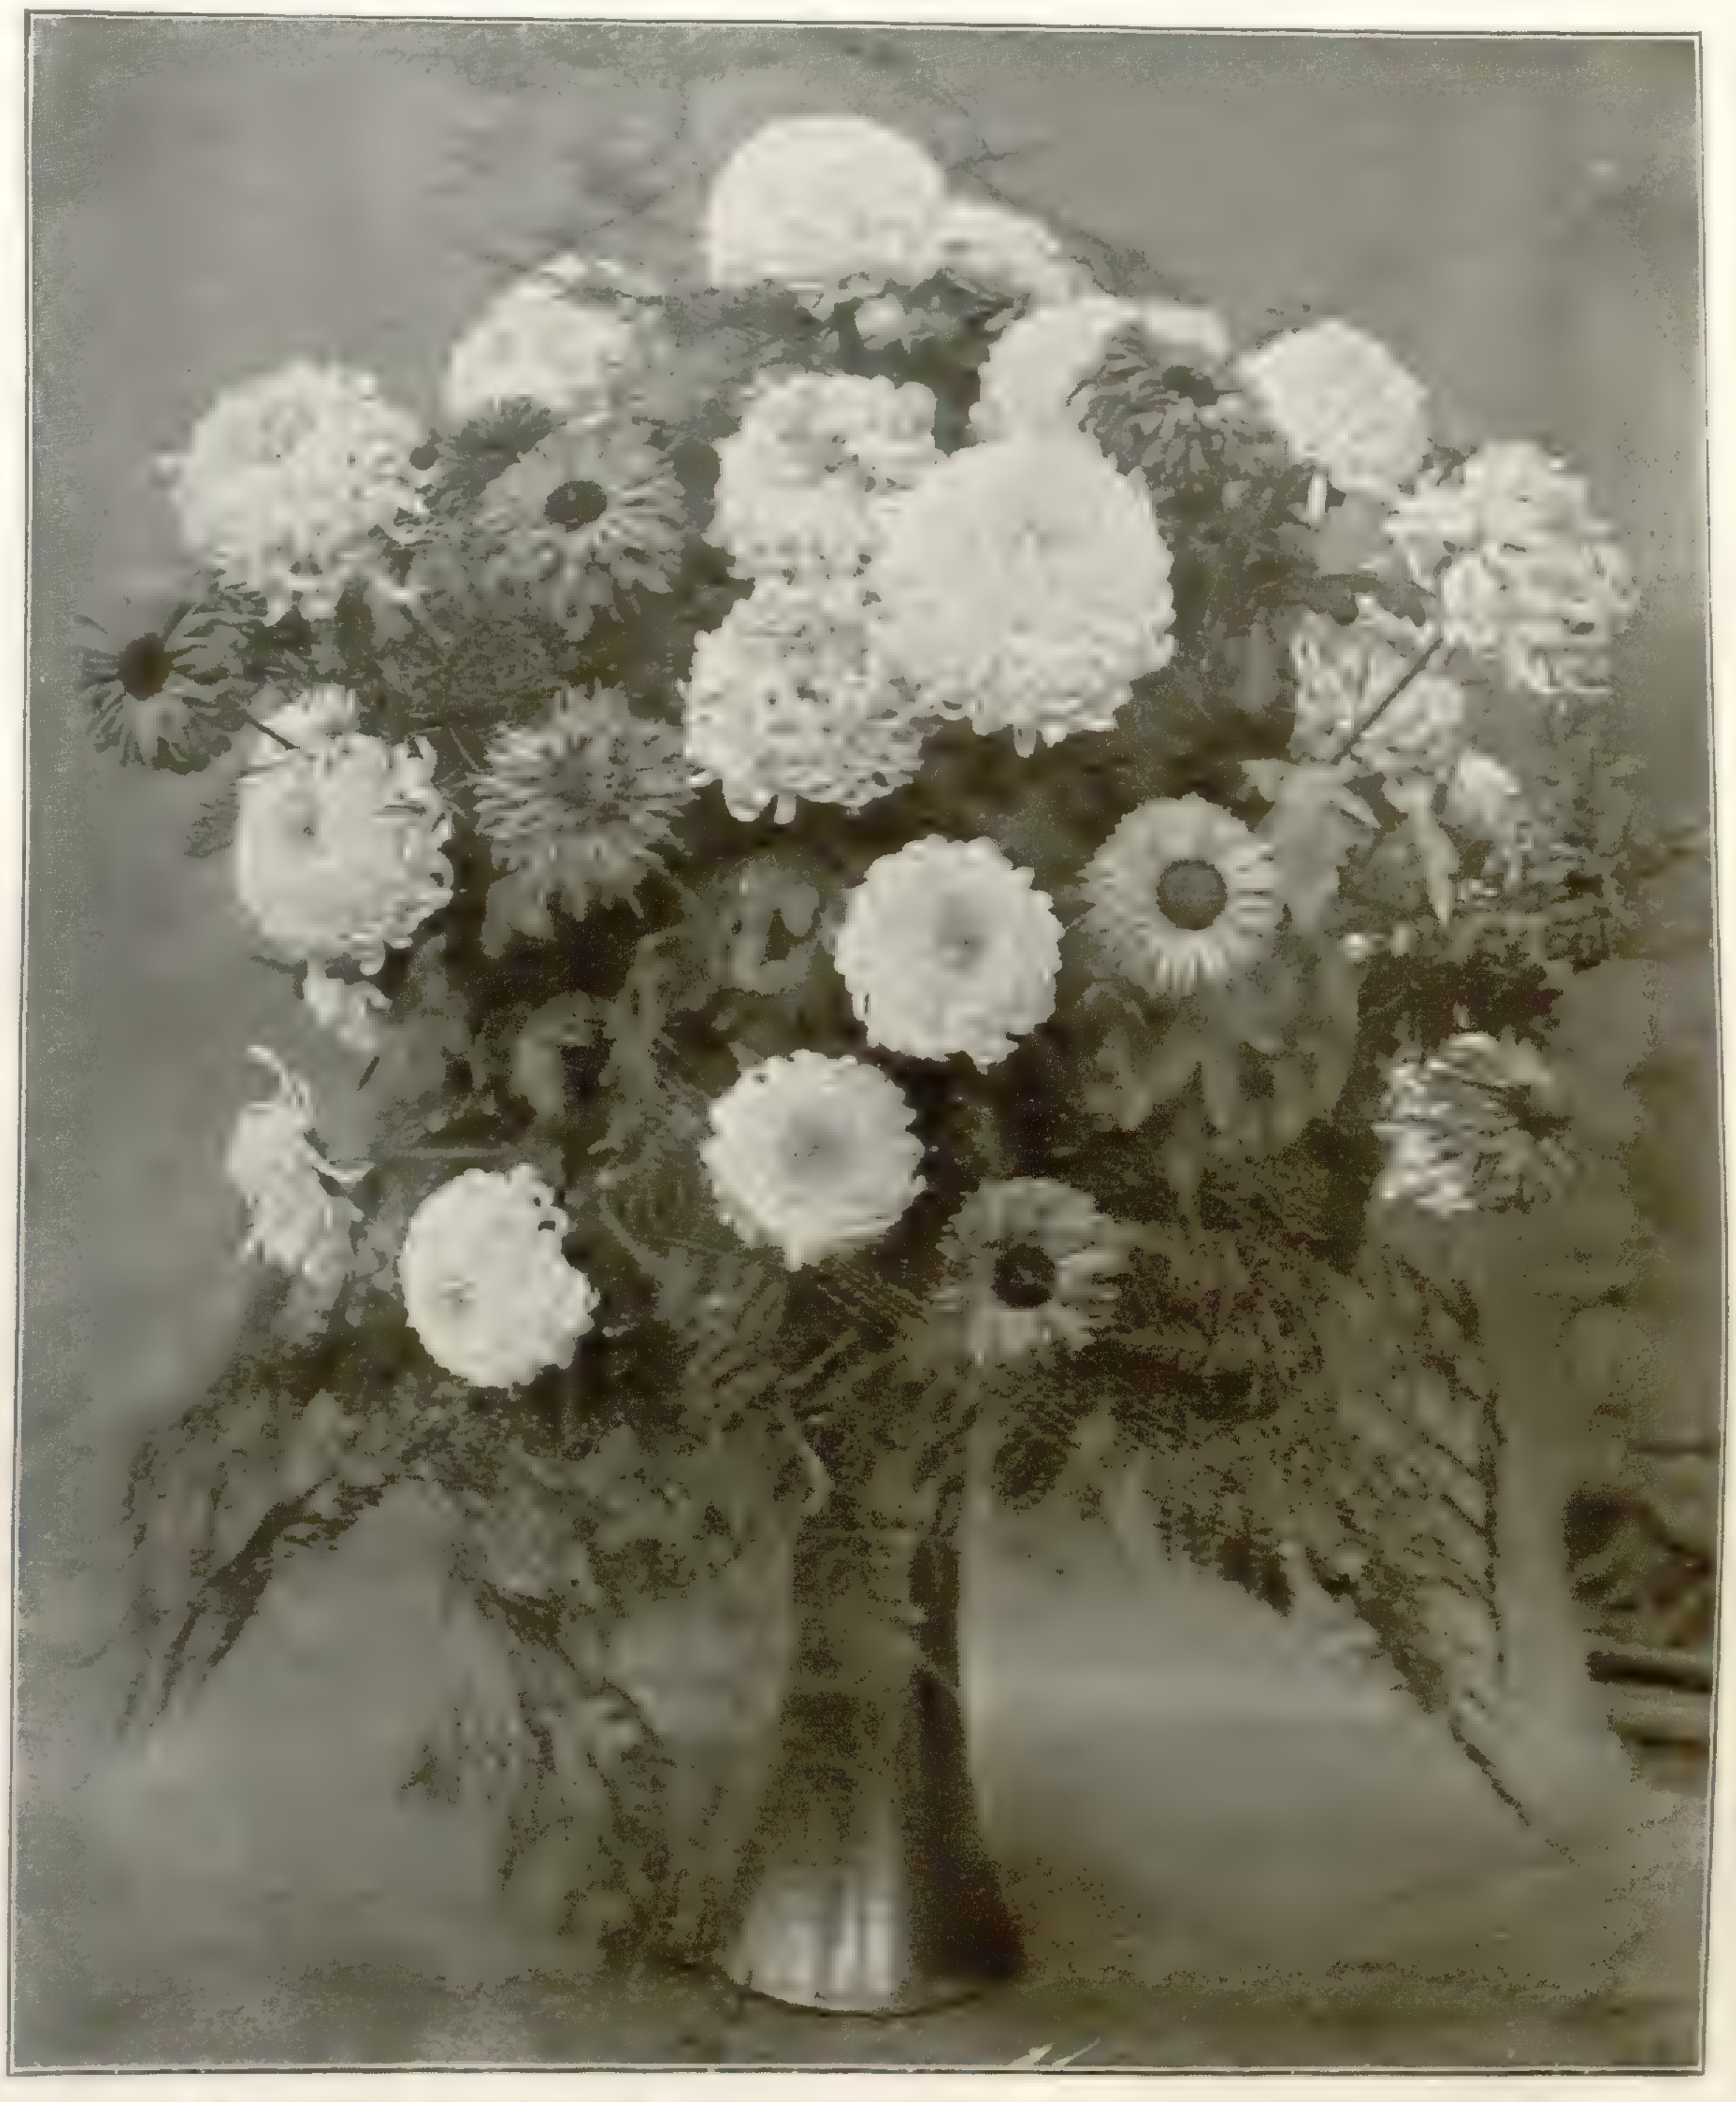
The layers are planted early in the autumn, the soil being made firm round the collar of each plant. At all seasons, after they are established, the hoe is kept going between them, not merely for the sake of keeping down weeds, but to aerate the soil and to prevent "greening" of the surface, to which this soil has a decided tendency. If undue moisture in the soil can be successfully combated, I regard a sea-side garden as being ideal for carnations. Much, of course, depends upon soils, but a great deal also depends upon the bracing air and salt-laden breezes, which act as a tonic to carnations.

In other gardens it has been my practice to treat carnations with salt spray by syringing, but now it is unnecessary, save for the indoor perpetual varieties, which are benefited by occasional sprayings. To grow carnations well demands continual attention. They are subject to many diseases, and varieties differ from each other in habit, constitution, and nature of blossoming very considerably, and growers must note as far as possible these particular vagaries of varieties under their charge.

On the other hand, one can by judicious treatment build a carnation up into health that has lost its vigour. Lady Hermione, Wanderer, Francis Samuelson, and others came into my hands in rather an undersized, weakly condition. Two years of soil improvement, of layering and selection from the strongest growths, has resulted in larger plants, which will necessarily give a finer and freer display of flowers. Carnations are not really subjects for mixed borders. If carnations must be seen in conjunction with herbaceous plants or annuals, I would prefer the continuous flowering annual carnations which are known as the early-flowering perpetuals, and can be raised in February, and will flower throughout the same summer.

With carnations all is progress. The fine varieties of recent years produced by Mr. James Douglas, the late Mr. Martin Smith, and others, have uplifted the whole race of carnations. We have not reached the climax yet. I am one who believes that there are finer varieties to come, but what I am concerned in is the fear that we are losing the fragrance of the old-world carnation in many of these new varieties. We must retain the clove-like fragrance as well as the robust growth, stiff stems, and finely formed and coloured blossoms, in order to retain the affection of the great British public for our old-world favourites.

P. S. Hayward.



A FINE VASE OF DECORATIVE CHRYSANTHEMUMS.
This vase, from Mr. A. Dyer, gardener to E. Wood, Esq., The Tyrol, Norwood, gained first prize at the Crystal Palace, on November 1, 2, and 3.

Zinnias.—Probably owing to the fact that the summer was very suggestive of their Mexican home, the zinnias did remarkably well. They withstood the drought better than most subjects, and the intense heat did not affect them in any way. It seems to me that for some reason or other we scarcely recognise the value of the zinnias for the summer embellishment of our gardens. They are readily raised from seed sown under glass in the spring, are not particular as to soil, and provided a sunny spot is given them, they will flower throughout the entire summer.—W. T.

VARIETIES OF APPLES.

The exhibition of British-grown fruit held recently by the Royal Horticultural Society tended to show what large numbers of varieties of apples there are at the present time in cultivation. Apart from bringing into prominence the large number of varieties that one might employ in forming a collection, it also indicated what a waste of space and time such a large number of sorts would entail.

Naturally, there is much interest in the introduction and distribution of a new apple, especially if it apparently includes such good points as freedom of growth, abundant production, and good cooking or dessert quality, as the case may be, a good keeper, and fruit of handsome appearance. If such an apple has all these qualifications, and, above all, is in season when other varieties of a similar character are scarce, it deserves to be popular and to receive encouragement from all interested in apple culture.

Certainly, this has been a season to really test many varieties, and perhaps more severely than I can remember. Here, where two hundred varieties under cultivation have been in the past, many have given crops this year which have not done so before to an appreciable extent. This emphasises the desirability of not including so many in a plantation. The more experienced of those who cultivate apples for market hold very strong opinions about the large numbers of sorts in commerce, and the majority of these growers set their face against new apples in quantity. Many grow a single tree of a newer kind on its introduction for experience in their own locality, but the tree soon finds a place on the rubbish heap if evidence is not forthcoming that the variety is not distinctly meritorious. In conversation not long since with a grower of several hundred acres of fruit trees, he expressed the opinion that three apples were quite enough for him, or, at the most, four, viz., Grenadier, Lane's Prince Albert, Bramley's Seedling, and Newton Wonder. This selection is exceedingly short, and, in my opinion, might be usefully extended, but we may assume that this grower understands his own business best.

What I wish to do is to point out the uselessness of certain apples in comparison with others of the same type, my object being to assist those about to make a collection. In this I shall be met with the remark, "All sorts you name will not succeed in my neighbourhood." This, too, I wish to allow for by naming varieties that are generally admitted to succeed everywhere.

Taking the kitchen apples first: We have a large number of varieties of the Codlin type. The best of these is Grenadier, which comes into use early, is robust in growth, bears freely, and is less affected with canker than any of its class. If we need another for small gardens Early Victoria is the one to plant. With this curtailing of sorts we dispose of Lord Suffield, Lord Grosvenor, Keswick Codlin, Golden Spire, and Marks Codlin. I have not a word to say against one of these except that they are not required. The next group of early varieties is composed of Ecklinville, Stirling Castle, Frogmore Prolific, Domino, Pott's Seedling, and Yorkshire Beauty. Grenadier will provide fruit in the place of any one of this batch, but for the sake of variety I would retain Stirling Castle. I shall be told by some that this apple is liable to canker, and does not grow freely enough owing to its heavy cropping propensities. Manure it well, giving liberal cultivation, and there will be no need to despise this dwarf-growing variety.

Now we come to a large section, comprising what is known as October apples. Cellini, Cox's Pomona, Emperor Alexander, Jolly Beggar, Queen Caroline, Warner's King, Wealthy, and Norfolk Beauty. I would adhere to the last-named, dispensing with the remainder as taking up too much space, not only in the garden, but in the fruit room also. The next group is a most useful one, consisting as it does of apples that give desirable fruit in November, December, and January. Here we can afford a little more latitude. Beauty of Kent, Bismarck, Blenheim Pippin, Gloria Mundi, Golden Noble, Hollandbury, Kentish Fillbasket, Lady Henniker, Lord Derby, Mère de Ménage, Peasgood's Nonsuch, Rymer, Small's Admirable, Stone's or Loddington Seedling, The Queen, Tom Putt, Tower of Glamis, Tyler's Kernel, and Gascoyne's Scarlet. Blenheim Pippin, Lord Derby, and Tower of Glamis are quite sufficient from this group.

Of the latest we have Lane's Prince Albert, Newton Wonder, Bramley's Seedling, Dumelow's Seedling, Alfriston, Annie Elizabeth, Beauty of Stoke, Betty Geeson, Hambledon deux Ans, Northern Greening, Sandringham, Striped Beaufin, Allen's Everlasting, Byford Wonder, Edward VII., and Reinette du Canada. The first three named in this group will give us some good fruit until May, and that is late enough for most purposes; and what quality could be superior to Newton Wonder or Bramley's Seedling for the latest supply, and as they are certain croppers, what need is there for so many? From a sentimental point of view, I ought, perhaps, to name Dumelow's Seedling (Wellington), which is really a good apple, but does not succeed everywhere like Bramley's, and certainly does not keep so long as that sterling variety.

In the dessert section there is also a wide range to select from. The earliest to ripen is the red and white Juneating, Mr. Gladstone, Beauty of Bath, Devonshire Quarrenden, Irish Peach, Duchess of Oldenburgh, Early Harvest, and Red Astrachan. Of these Beauty of Bath and Mr. Gladstone are preferable, and really these early apples are more in the name of an apple than aught else. The next group that I will term September apples, is also a large one. Williams' Favourite, Lady Sudeley, Pure Apple Russet, Summer Golden Pippin, Yellow Ingestrie, Worcester Pearmain, Ben's Red, St. Edmund's Russet, and Miller's Seedling. Lady Sudeley and Worcester Pearmain are here preferred.

Of October varieties Benoni heads the list with James Grieve, Rival, and Charles Ross in close attendance; American Mother, King Pippin, Scarlet Pearmain, and Egremont Russet. The first three are preferred. In the next division—those for November and December—we find most desirable varieties with less rigid selection. Cox's Orange Pippin stands quite at the head of all others, and with care it can be grown almost anywhere. Ribston Pippin comes next, closely followed by Blenheim Pippin. These three are quite sufficient, although we have King of the Pippins, Allington Pippin, Margil, Winter Ribston, Christmas Pearmain, Claygate Pearmain, Colonel Vaughan, Fearn's Pippin, Mabbott's Pearmain, and Winter Quarrenden. The first three are quite sufficient to provide fruit of the highest quality; in fact, I have no hesitation in saying that where Cox's Orange Pippin succeeds no other need be grown, as the fruit of this, properly stored, will keep until March; but there is so much sentiment about Ribston Pippin or I would otherwise gladly leave it out.

For the latest supply I name the following sorts, but I have not much faith in their quality. I contend that when Cox's Orange Pippin is exhausted we have not an English apple that can compare with many of the British Columbian and Tasmanian varieties, like Grime's Golden Pippin, etc. Of the varieties in cultivation there are King of Tompkin's County, Cockle Pippin, D'Arcy Spice, Duke of Devonshire, Lord Burghley, Lord Hindlip, Mannington's Pearmain, Northern Spy, Ross Nonpareil, Wyken Pippin, Sturmer Pippin, and King's Acre Pippin. Of the batch I prefer the first-named D'Arcy Spice and Wyken Pippin.

Practical Fruit Grower.

FRUIT GROWING.—Full instructions as to planting, pruning, and management of fruit trees are given in Profitable Fruit Growing (Ninth Edition) —a gold medal essay by John Wright, V.M.H.—price 1s., or by post 1s. 3d. from Gardeners' Magazine Office, 148 and 149, Aldersgate Street, London.

SALADING IN WINTER.

It is comparatively easy to produce and maintain an unbroken supply of salading during the summer months, but from now until the month of April some amount of forethought and attention to details will be needed to supply a continuous demand. The wholesomeness of salads is well known, and the more variety one can provide the better. In most large establishments salads are required almost every day in the year.

The worst enemy to guard against with most salad plants during the dull days is damping, following after frosty and snowy weather. This is far more fatal to the plants than actual frost. Means should be taken to grow them under well-glazed lights, and these must be placed in position when excessive rain or snow falls, but must be removed when the weather is fine, as coddling must be assiduously avoided.

The mainstay for the salad bowl is lettuce and endive, and, assuming that strong plants are available in the open quarters, they should now be lifted with a good ball of soil and planted in prepared frames, or the smaller ones may be boxed, and the boxes accommodated on shelves in fruit houses. Avoid crowding or damping will result. Each plant should stand quite clear of its neighbour. The cos varieties will need a tie in order to blanch them, and this operation must be performed when the foliage is quite dry. The cabbage lettuces need no attention in this respect. Both the curled and Batavian endive must also be duly tied as required, for the same reason. A fortnight will be required to blanch them well.

I find All-the-Year-Round cabbage lettuce a suitable variety. Let the soil be fairly rich and porous, and keep the plants near the roof glass, say, six inches below it. In gardens where the glass becomes coated with soot, it should be frequently washed to admit the maximum amount of light. Later on, when the lifted plants are nearly finished, recourse must be had to seedlings raised well beforehand. These must be pricked out in shallow boxes, and grown freely in a genial temperature, but always near the glass, or they will become drawn, and will consequently not go far when cut up. At the same time these should be grown quickly to ensure tenderness.

To maintain the supply of mustard and cress is an easy matter. Sow weekly, and apply water before sowing; if this is done it is but seldom that any more will be required before it is cut. Cress should be sown two days before mustard, as it is longer germinating.

I invariably grow a few pans of watercress for picking in winter. All that is required is to insert a handful of cuttings occasionally, and when rooted pinch out the heads for use. They will quickly branch out, and produce an abundance of tender shoots. This process is not necessary where watercress is grown naturally.

Tomatoes are indispensable to the salad bowl, and in most establishments a few may be obtained during the winter, if strong plants have been raised in autumn.

Chicory is easily grown in open quarters during the summer, and if not already done, the roots should be lifted carefully and plunged in dry sand for forcing as required. This is a useful salad plant, but large quantities are not required at one time, therefore half a dozen roots may be placed in a large pot in the mushroom house, with an empty pot of the same size placed over it, and this operation may be performed at intervals according to the demand.

H. T. Martin.

Now is the time
to plant
Kelway Paeonies

With their gorgeous profusion of varied tints, Kelway's lovely New Paeonies make splendid decorations for the house. They present a glorious spectacle when growing, either in massed groups or arranged with other herbaceous plants in the Kelway "Artistic" Border. Many varieties have the added attraction of a most delicate and delightful perfume. They will thrive in almost any position and need no protection whatever.

Choice named Collections of Kelway Paeonies: 27/-, 36/-, 54/-, 70/- a dozen

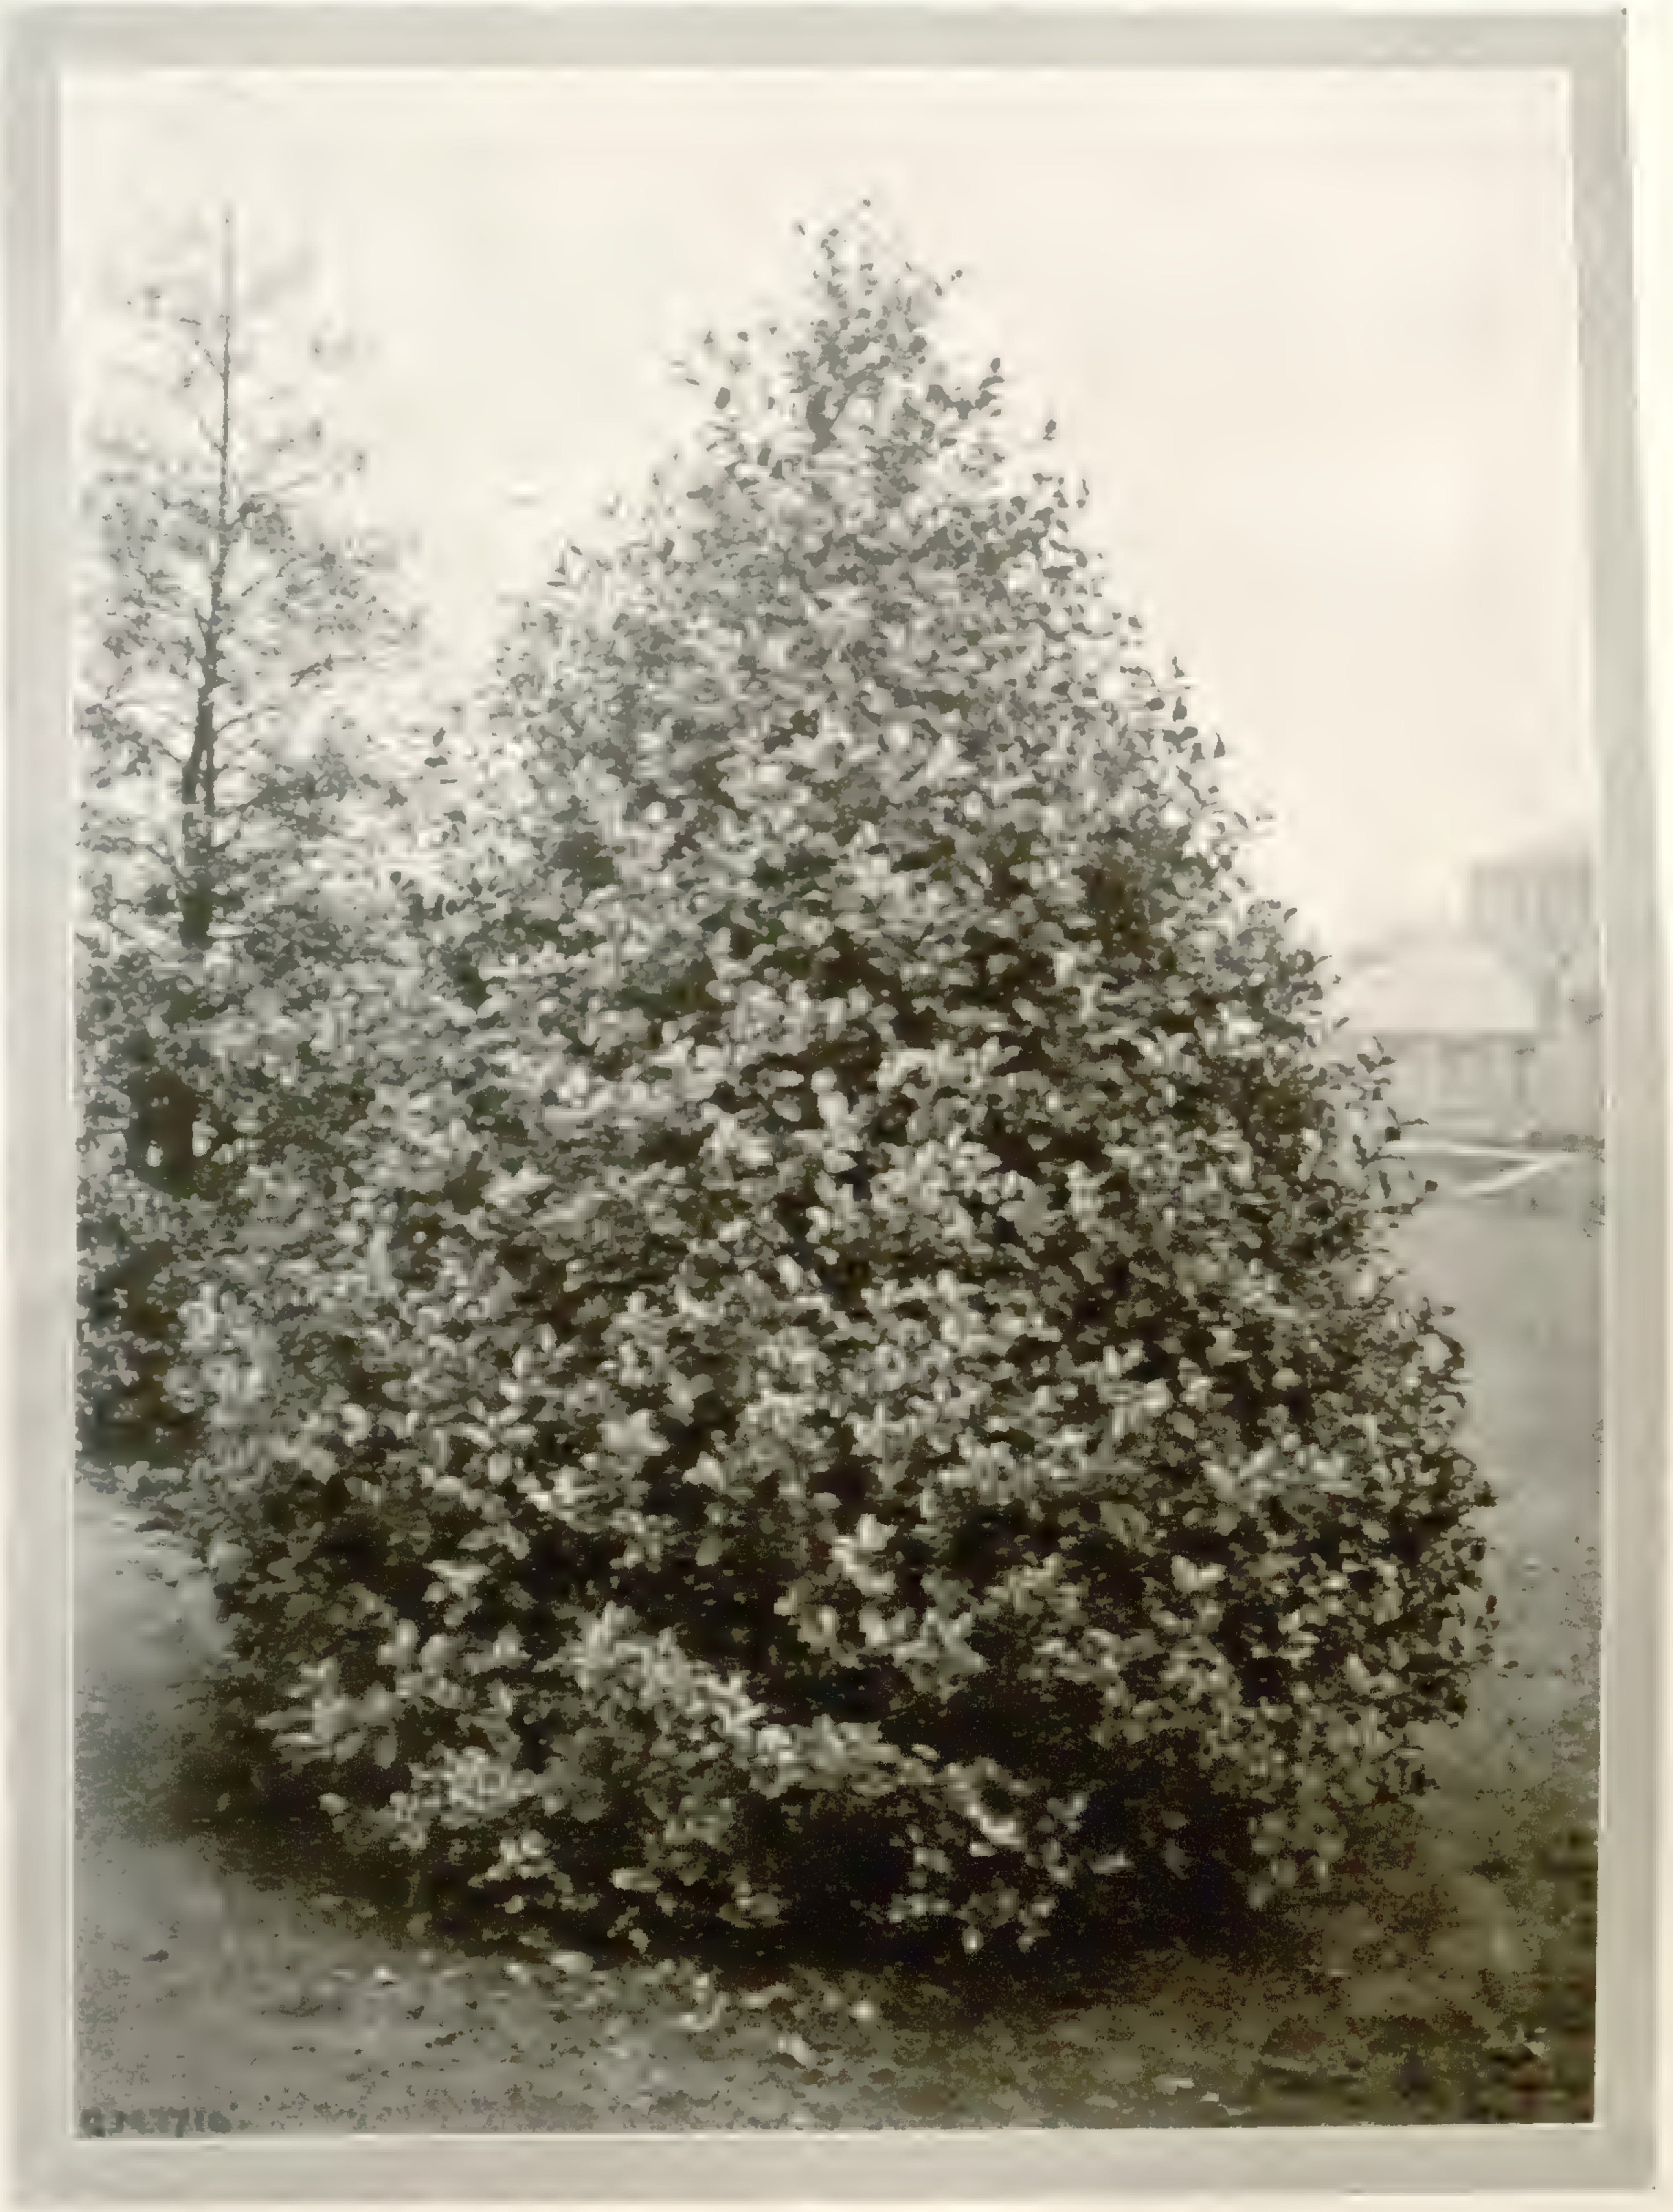
AN EFFECTIVE GOLDEN HOLLY.

The number of hollies with golden variegation is considerable, and although a small proportion only will be required in any one garden, they possess, with but few exceptions, much merit for giving a bright touch of colour to the shrubbery border and for planting as single specimens in prominent positions on the lawn. The leaves of the majority of the golden hollies have a well-defined marginal band of gold, and their effectiveness depends in a large degree upon its breadth and brightness. The most noteworthy of the hollies of this class is the variety known as Golden Queen, and equally remarkable for its broad leaf-margin and the intensity of the colour of its variegation. There is another class of golden hollies, in which the variegation is not confined to the leaf-margin, but spreads over the leaf in a more or less irregular manner, and to this the distinct and handsome variety known as Madame Briot belongs. It is a form of Ilex aquifolium, and has a vigorous free-branching habit, and has full-sized leaves, of which a considerable proportion, as indicated in the accompanying illustration, are of a bright golden hue. It is one of the most effective of the many handsome hollies that are now at the command of the planter, and it has special claims for consideration, inasmuch as it is quite distinct from the other varieties in gardens. Madame Briot is not new, but it is not as yet generally known, and is consequently seldom seen in gardens. The specimen herewith illustrated has a place in the Kew collection of hollies, and is between seven and eight feet in height. In the beautiful gardens of Hillingdon Court, the Middlesex seat of Lord Hillington, there is a finely-proportioned specimen, about two feet higher than that at Kew, and, enjoying highly favourable atmospheric conditions, it is especially remarkable for its rich colouring. G.



ILEX AQUIFOLIUM MADAME BRIOT.
A free-growing and effective holly, with golden variegation.

PARROTIA PERSICA.

There are two periods of the year when this Persian tree is attractive. Firstly, in March, when the leafless branches are thickly studded with small, but conspicuous red blossoms, and, secondly, in autumn, when the leaves have taken on their gorgeous colour previous to falling. At the latter time it is easily one of the showiest trees of the garden, for the leaves, which are not wholly scarlet, are a mixture of scarlet, red, orange, and green. The size of the leaves is in their favour, for the larger ones are nearly six inches long and three inches wide, thus giving a boldness which is less noticeable in smaller-leaved plants, which are also remarkable for their autumn colouring. Parrotia persica is allied to the hamamelis, but it appears to be less well known than those showy shrubs, though it has been in cultivation for a longer period than the Asiatic species of the genus.

The genus Parrotia has but one other hardy species, so far as is known, that being P. Jacquemontiana, from the Western Himalaya. That is a very different plant, for its flowers are borne in summer, and they are only redeemed from insignificance by their attendant white bracts. The leaves, moreover, have nothing to recommend them in autumn, for although many of them turn yellow, the plant is never really effective. Nevertheless, it is a very distinct and interesting plant, and well worthy of inclusion amongst choice small-growing trees. W. D.

OCTOBER NOTES.

We are experiencing a real "Indian summer," and the garden is quite a pleasurable place at this time, October 12. The few rains have freshened everything immensely, and now, with blue skies and warm sunshine, blossoms are much more plentiful than is usual at this season.

The new lease of life is apparent in many plants. Groupings of Michaelmas daisies grace the banks and slopes of the informal parts of the garden, and the diversity of hues, forms, and habits makes this group of plants wonderfully attractive. The collection is just now at its very best, and the shades of purple, blue, lavender, pink, rose, and white, in continuous yet informal groupings upon the sloping banks, give an effect that is pleasing and if interest. It is worthy of remark that no one need forego the pleasure of a good collection of Michaelmas daisies. So many sterling varieties have been put into commerce during the past few years that we have ample from which to make a good selection. Furthermore, the raising of seedlings is interesting, and usualy yields some pretty varieties, if one can give the space and time for careful selection. Single chrysanthemums, both the seedlings and those propagated from cuttings, are giving a good display pust now, and are among the most valued of garden plants for autumn display. Utilised in groups upon rising ground, with the varied colours blending artistically together, the single chrysanthemum is of first-rate merit. Freedom, wide colour range, and long season of flowering, are all in favour of these plants. The double forms are just as attractive, albeit just a trifle heavy in comparison, and the splendid series of varieties considerably enhances their interest to the garden-lover.

Erigeron speciosum Quakeress, with its pretty daisy-shaped blossoms of a soft lavender hue, is very noticeable just now, and is a very useful subject for garden decoration or for cutting. Gauras are just as delightful as ever, the wealth of slender, waving stems being laden with the snowy "butterfly" blossoms. Gaillardias continue to throw many blossoms, and Mimulus cardinalis, Chrysanthemum maximum in variety, and the statices still continue to blossom. The delphiniums have at last spent their energies, but Aconitum Fischeri gives of its deep blue colour. Vernonia arkansana is gay with its purple-hued heads of blossom, and is worthy a place in every garden of hardy plants. Pentstemons still linger with us, but the spikes are very inferior to what they have been.

It is curious to note how some plants of Caltha palustris are giving us golden blossoms at this season. C. polypetala has shown no signs of this springlike activity, but its humbler companion is quite bright. Several of the ericas are in blossom, and one must remark upon the value of the hardy heaths. The E. vagans varieties are among the best of those flowering,and many varieties of Erica vulgaris are in blossom. The pretty Tamarisk hispidus æstivalis is charming still in growth and blossom. For many weeks the pink feathery plumes have been produced most profusely, and a group of these shrubs is decidedly a fine attraction.

Verbenas upon the slopes are still gay with colour. The value of these old favourites is often noted, and Mr. Molyneux in a recent issue of the Gardeners' Magazine, notes with evident pleasure the collection of verbenas at Aldenham, which has evidently been carefully selected by Mr. Beckett. These plants seem to be coming into full favour again, and we ourselves have this season many which are decidedly in advance of previous cultures. Many of our own varieties may be replicas of Mr. Beckett's, and of other growers, but this does not lessen the value of the verbena. In connection with these notes I may mention a verbena species from South America, which was given me for trial by Mr. R. W. Wallace, and has given us a wealth of the most intense scarlet blossoms since early in the summer, and is a mass of beauty. It is of light growth, and the trailing stems are woody in character; it is especially valuable for rock gardens. Colchicums have passed out of blossom except C. cilicicum, which is just now at its best. It is with pleasure that we still note blossoms of the nymphæas, several still showing during the sunny days. Zauschnerias and Plumbago Larpentæ are still bright, and many of the rock garden violas have taken on a new lease of life.

DESSERT PLUM, COE'S GOLDEN DROP.

The fine dish of this richly-flavoured variety shown by Mr. W. Messenger, Woolverstone Park, at the R.H.S. exhibition of British-grown fruit.

Planting out in the wild garden and on the sloping banks and hillocks is still proceeding. It is our aim to extend the season of blossom as far as possible, and all classes of bulbous plants, and large numbers of Iceland poppies, myosotis, campanulas, foxgloves, cowslops, primulas, violas, etc., are planted up among the plant and shrub groupings already in existence. Arabis, aubrietias, and alyssum also enter into our plans, and largely and freely contribute to a glowing spring display. Helianthus and Pyrethrum uliginosum give masses of blossom in the background, and are useful if not allowed to encroach upon other subjects. All rank-growing herbaceous plants should be lifted, if possible, each season after flowering, as this tends to keep them in better health, and assists in maintaining good-habited specimens.

Herbaceous borders should be overhauled, if not previously done, and all ground where herbaceous plants are cultivated should be worked as freely and deeply as possible. Manure should not be denied these plants wherever it may be needed, as the majority have the power of assimilating large quantities of available plant food.

And, in conclusion, may I urge the fullest attention to selection? This, we regard as one of the most necessary phases of all garden work, as all plants are capable of improvement, and the constant watching of plant life, the careful noting of all points of interest, and the gradual weeding out of inferior forms, is a well-rewarded task, and is, moreover, replete with interest.

P.

Amphicome Emodi.—The date of the introduction of this amphicome is given as 1852, but it is only within the last few years that general attention has been directed to its merits. It belongs to the order Bignoniaceæ, is of a herbaceous character, and when in flower suggests a close affinity to Incarvillea Delavayi. The blooms, which are freely borne in clusters on stalks well above the pretty pinnate foliage, are rose-pink, with an orange throat. It is a native of high altitudes in the Himalayas, and is hardy in favoured parts of the country. Even where not hardy it is a valuable decorative plant for the greenhouse in late summer and early autumn. It may be readily increased by seeds, and is not at all difficult to grow.—W. T.

CHOICE DESSERT PLUMS.

Where the private grower has to meet a constant demand for choice dessert fruits, the plum forms one of the most valuable and highly prized of the kinds available. Where the convenience exists for keeping up a regular and uninterrupted supply from early in August to the middle of November, the number of first-class varieties to select from is ample for the purpose.

Taking everything into consideration, trees trained on walls are the most satisfactory, and if various aspects can be utilised the number of varieties need not be extensive, as by planting the same variety on a south or south-east, and also on a west wall, a succession can be obtained over a considerable period. This is a matter of some importance where particular varieties are held in high estimation. Grown as bushes or standards, the difficulties in securing a regular crop are so gerat that "the game is hardly worth the candle." In many districts the birds are decidedly troublesome, striping out the buds wholesale; if, purchance, a few blossom buds are saved by persistent spraying, there is the later difficulty of protecting the fruits from further attack.

By erecting wire-netting protectors it is possible to outwit the bird and thereby secure a crop. This is, however, a somewhat expensive business, and if wall space is available, it is undoubtedly the most suitable for the purpose. The trees during the flowering period can be adequately protected from frost. Birds can be effectually excluded from taking the buds, and later from sampling the fruits. If wasps are very much in evidence, the fruits can be placed in muslin bags. In giving a selection of varieties in their order of ripening, I would give first place to Early Transparent Gage, a handsome, richly-flavoured fruit, ripening about mid-August. Denniston's Superb, a medium-sized, pale yellowish-green fruit, ripens about the same time as the Early Transparent, and is a good comparison to that esteemed variety. Following on the heels of the above varieties comes the old Green Gage, still one of the most delicious plums grown. Jefferson's—a grand variety in every way when thoroughly well grown and finished—is one of the finest varieties we have. It makes a telling dish on the dinner table and the exhibition stage. Kirke's, a large, roundish oval fruit, carrying a beautiful bloom, is usually considered to be a shy bearer. I have two large trees on a S.S.E. aspect, which have never failed to produce a crop for the past eighteen years, and I consider it to be one of our most valuable plums for late August and early September use. The fruit travels well, the flesh being firm, and it keeps in good condition for some time. Decaisne, a large oval, yellow plum, resembling Coe's Golden Drop in appearance, and ripening in the early part of September, should be included in every collection of importance. Washington, which ripens about the early part of September, is a fine large fruit, but I do not consider it to be so good as the above-named varieties, and I have discarded it in favour of varieties of more value.

The good qualities of the Gage family are so well known that further praise is unnecessary. Early Tranparent Gage I have previously noted. Bryanstone Gage and Comte d'Althan's Gage ripen about the same time, namely, the middle of September, and are both valuable plums of first-rate quality. Transparent Gage is slightly earlier in ripening than the last-mentioned varieties, and is without doubt one of the most delicious plums grown; this is a variety which should be planted on various aspects to extend its season as long as possible. The tree is a somewhat awkward grower, and if the spurs are pruned back too closely it occasionally fails to produce blossom buds; therefore, it is advisable to prune moderately.

Late Transparent Gage is of value in extending the Gage season, and being a robust, healthy grower,there is no difficulty in building up shapely trees. Golden Transparent, a variety of more recent introduction, has come rapidly to the front and is now largely grown, and deservedly so, the fruits being large and handsome and of rich flavour, coming into use so late in the season makes it all the more valuable.

An old favourite, and one of the best, is Coe's Golden Drop. This is a grand variety; its large oval-shaped yellow fruits, dotted with a number of dark red spots, make an attractive dish for table or exhibition. The flavour is superb, and it has the additional advantage of keeping firm and sound for a considerable period if carefully gathered and stored in a cool, dry room. Coe's Violet is unique in its way; the thin stripe of violet running down one side of the fruit stands out clear and distinct on a groundwork of reddish-purple on the sunny side, yellow on the shady side. Size and flavour are identical with Coe's Golden Drop. So far as I am aware, this variety is but little known; it is, however, worthy of inclusion as a first-class late variety, if only for its distinctive beauty.

Another fine late variety is Reine Claude de Bavay. Ranking as one of the best, its large round fruits are perhaps not quite so attractive to the eye as many of the more highly-coloured fruits. The flavour, however, is very rich and sweet; in fact, if allowed to hang on the trees until slightly shrivelled, it is more like a sweetmeat, and is then delicious. If stored in the same manner as Coe's Golden Drop it will keep in good condition for some weeks.

The latest variety I am acquainted with is Late Rivers, a dark purple plum of excellent flavour, certainly a most useful variety, sustaining the supply well into November; a variety not so well known as its merits deserve.

There is one more variety that I must mention, namely, Cullin's Golden Gage, a handsome golden fruit, usually carrying a crop in adverse seasons. The flavour, however, I consider quite second-rate, and the fruits grown here are used for cooking purposes, for which it is excellent.

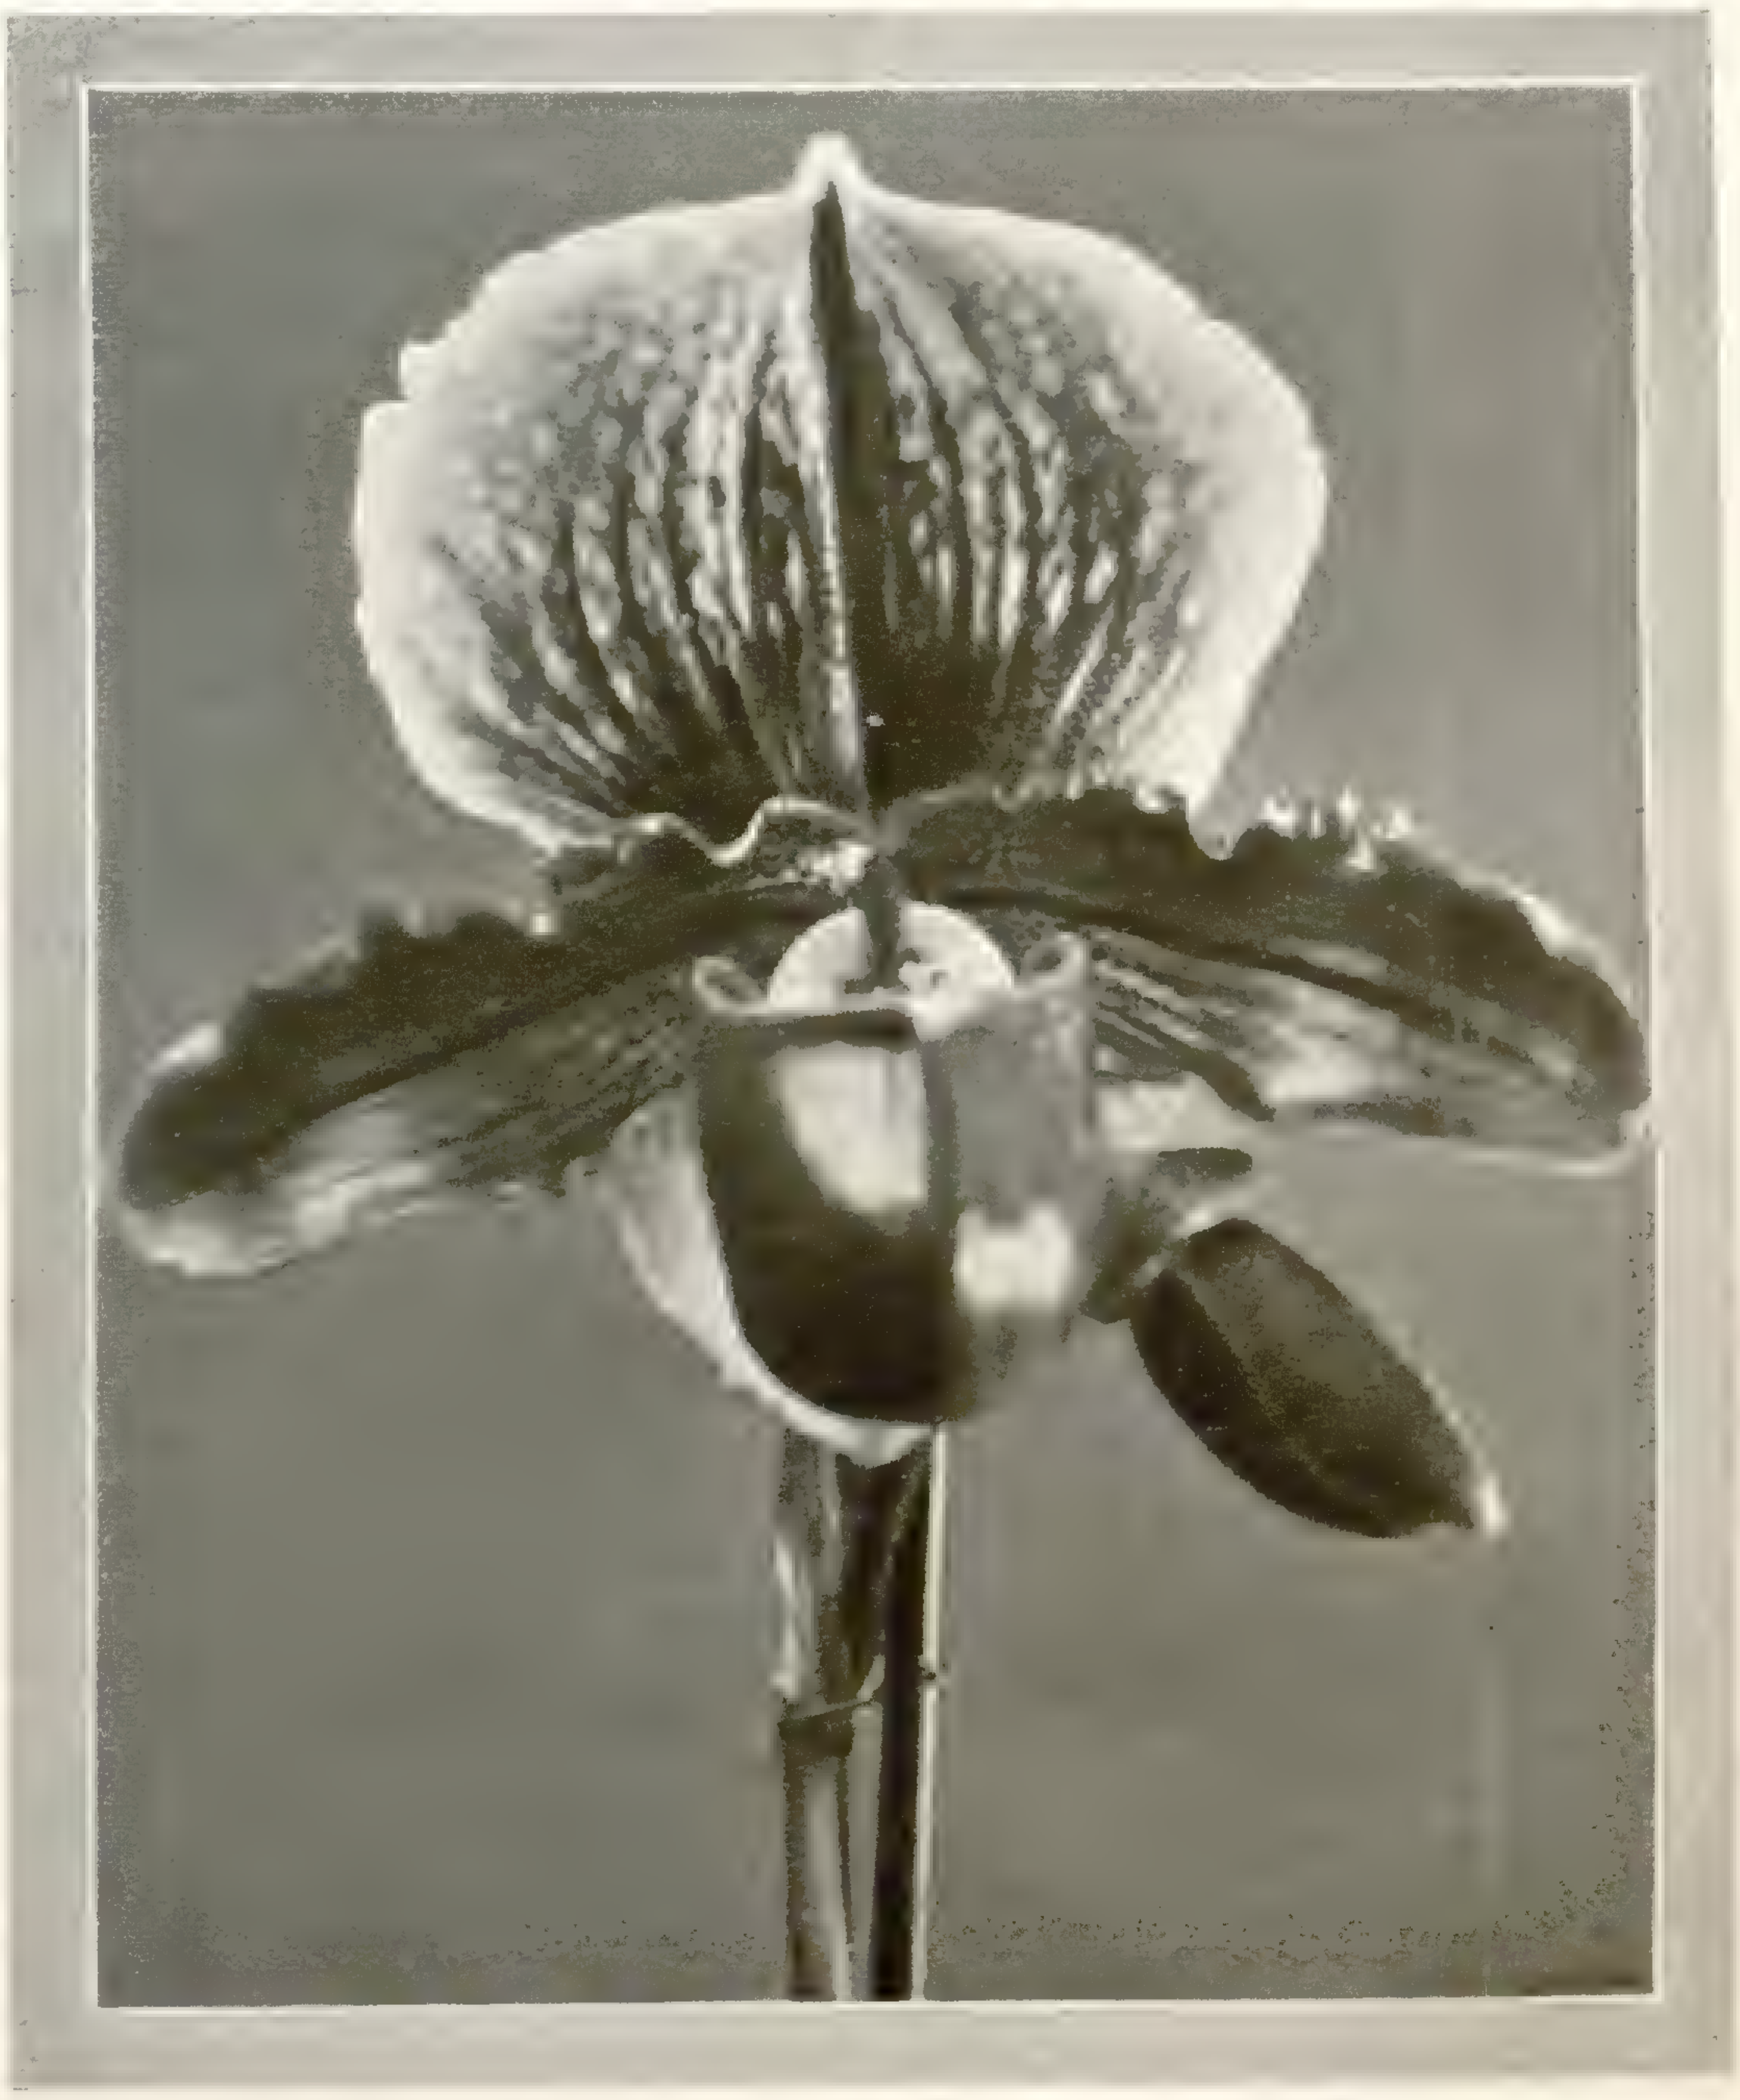
The general culture and management of the plum has been most ably set forth by previous writers, that further details are unnecessary. I would, however, press home the necessity of early thinning of the fruits when it is certain the trees have set a heavy crop. To produce fruits of the highest excellence the tree must not be overburdened, and a thought should be given to the welfare of the tree and the prospect of a crop the following season.

W. Messenger.

Amellus Asters.—Mr. Arnott does well to draw attention to these perennial asters, as they really do not find sufficient encouragement in the garden, where their decorative value is undoubted. I lately saw at Aldenham a big batch of seedlings, and among them were many forms and colours of pink and rose shades. These two latter are most desirable, as they give variety to the class, among which, generally speaking, these shades are in the minority. In a cut state, too, these pink shades are most valuable, as they light up under artificial light so beautifully. Mr. Beckett has great hopes of a clear yellow, which would be a novelty in asters.—E. M.

CYPRIPEDIUM LUCIFER.

Nowadays a cypripedium has to be of outstanding merit, or the possessor of great distinction in form of colour, to obtain a First Class Certificate from the Orchid Committee of the Royal Horticultural Society. There are already so many fine cypripediums in general cultivation that the standard required in a novelty is now extremely high, and any hybrid that reaches that standard is worthy of more than passing notice. On the occasion of the Royal Horticultural Society's Fruit Show, when comparatively few people were present to give attention to orchids, Cypripedium Lucifer was displayed in an upper room by Mr. H. G. Alexander, orchid grower to Lieut.-Col. Sir G. Holford, Westonbirt, Tetbury, and it attracted the attention of all who saw it by reason of its shapeliness and fine colouring. This hybrid, illustrated in the present issue, was obtained by crossing the very neat and pretty C. Niobe, Westonbirt variety, with a fine form of C. Hera Euryades, a bold, large, and handsome variety. In C. Lucifer the rounded dorsal sepal is white, with a central deep rose-purple band, and shading and veining of a paler shade of purple over the base and centre of this showy portion of the flower. The greenish-yellow petals are broad, heavily shaded with purplish-brown, and the lip is bright and rich red-brown. This, and Cypripedium Royal George, shown on the same occasion by Mr. Francis Wellesley, form a splendid pair of new and distinct hybrid Lady's Slipper orchids.



CYPRIPEDIUM LUCIFER.

Flowers white, purple, purple-brown, and red-brown. F.C.C., R.H.S., October 10. Lieut.-Col. Sir G. Holford (grower, Mr. H. G. Alexander), Westonbirt, Tetbury.

PERIPLOCA GRAECA.

This strong-growing climber is a native of South-eastern Europe and the Orient, but it is hardy enough for culture in the open ground in many parts of this country. Quite recently several vigorous examples were noted in the South of Scotland which in July were in full flower. P. græca shares with other members of the Asclepiad family the peculiarity of producing thick milky juice in stems, roots, and leaves, which is emitted on any slight incision being made. The purple star-shaped flowers are borne in moderately large heads; their colour is, however, too dark for them to be really conspicuous. Planted in loamy soil it grows rapidly, and quickly attains a height of twelve or fifteen feet. Though often planted against walls, it answers even better when allowed to wander at will over a large bush or low tree, for in such a case there is no necessity for cutting the branches back periodically to keep them within bounds, as is usually the case with wall-grown examples.

D.

Vitis heterophylla humulifolia.—This Japanese vine would appear to be fruiting with unwonted freedom this season under the influence, probably, of the hot summer. If the fruit is not of value from an edible point of view, it is decidedly ornamental, the berries when ripe being of a pleasing shade of purplish blue. The vine is of easy propagation and free growth, but needs to be given a warm sunny spot to ensure the production of berries.—W. T.

FLORISTS' FUCHSIAS OUTDOORS.

The fuchsia is a plant which is admirably adapted for growing both under glass and in the open, though some varieties are better suited for one purpose than the other by reason of their varying habits of growth. It is said to be a great lover of the night air, probably on account of its dampness, and when grown under glass it never seems to have that vigour of growth, darkness of foliage, and substance of blossom which we are accustomed to see in well-grown outdoor specimens. In favoured parts of the country, such as the south and west, especially near the sea, there are few more beautiful things in the garden than the great masses of hardy species of fuchsia, which stand the winter and become shrubs, escaping mutilation by frost for several years together. Even in less favoured districts, where they may be cut down to the ground two years out of three, these hardy kinds are worth growing, becoming, as they do, even under the worst conditions, herbaceous plants.

The kinds, however, of which I wish more particularly to speak are the stronger-growing florists' varieties, which make fine specimens for the garden, either for growing in tubs or pots, or putting out in the open ground for the summer months. The blossom of the fuchsia being of a drooping character, it is advisable that the plants should be so grown, or so disposed, that the flowers are some height above the ground. In the greenhouse or conservatory this can be done by putting those varieties of small growth and pendent habit on the staging, but in the open we must have erect and strong-growing varieties, unless they are to be given elevated positions, as on terraces, window balconies, etc. Though some varieties refuse to conform to it, the pyramidal form is the one to be aimed at, either with a clear stem, when they become standards, or branching down to the level of the soil.

The propagation of the fuchsia is of the simplest, pieces of healthy young growth, an inch or an inch and a-half long, with a heel of the old wood attached if possible, striking at any time of the year in heat, or in a cold frame in the spring and summer. Assuming that strong, upright-growing sorts have been chosen, they should be trained to a single stem by keeping the side shoots pinched in sufficiently to ensure the predominance of the leader. If the cuttings are taken early in the year, and kept in gentle heat till the summer, nice plants one to two feet high may be obtained the first year, but anything like forcing is a mistake for plants which it is intended to grow in the open air. It is better to sacrifice early display, and, after they are well rooted, grow the plants in a cold house or frost-proof frame till June is well in, and then put them out in the open for the summer. For the first winter, as they will have little or no ripened wood, they should be kept in a cool house from which frost is excluded, and after that never subjected to heat again. Afterwards they may be wintered in a cellar or outhouse of any sort where they will not be exposed to any serious degree of frost.

The great secret of getting sturdy and vigorous plants is to let them make the whole of their growth in the open. We have all seen plants brought out of their winter quarters in March, and put in a warm house, where they have started into luxuriant growth, subsequent exposure to sun and wind browning their leaves and checking their growth the rest of the season. They should be kept back in the spring as far as possible, and the less growth they make before May the better.

Young fuchsias respond more quickly than most plants to repotting when their roots are not disturbed, although when they become of large size this is often impossible. A good compost to use is one consisting of two parts turfy loam, one of leaf-mould, and one of old hotbed manure, with a liberal addition of coarse sand or finely-broken potsherds to keep the soil open. When they get large, so that repotting is only done once in a couple of years, lasting plant food, such as basic slag or bonemeal, should be added to the compost at the rate of a pound to the bushel of soil.

It is difficult to repot large fuchsias without disturbing the roots a good deal, as these are brittle, and do not form such a fibrous mass as those of some plants. If they are to be put in fresh pots of the same size—always clean ones—and they have been turned out of the old pots whole, or nearly so, it is a good plan to work out some of the earth from the roots with a hand fork. The soil should always be nicely moist before a shift, and, assuming this is the case, no water is necessary afterwards until the soil, both new and old, has become fairly dry, this drying out of the moisture and the taking of its place by air giving the plants a good start in the new pots, for if the new soil is soaked when there are no roots in it to absorb the moisture there is a danger of it becoming sour, and this is fatal.

The same principle applies to all old plants in large pots or tubs, the soil in the lower part of which may not get dry the whole summer. If such are allowed to get thoroughly dry once in a while, even to the flagging point, the soil will be sweetened, and the plants will be the better for it. For feeding I have found nothing better than good guano and dissolved bones, once a week with each. Old plants in large pots stand much stronger applications than young ones, and it is doubtful if the former should ever be watered with plain water except in very hot weather, and in the resting season, always remembering, however, that when the soil is very dry, it should be thoroughly moistened with clear water as a preliminary to the liquid manure.

It is scarcely worth while enumerating varieties for outdoor purposes. As a rule, single varieties are stronger in growth than the double, but there is one exception at least which should be mentioned, as it is one of the best I know for our purpose, and that is that grand variety Madame Jules Chrétien, with scarlet sepals and semi-double white corolla veined red. I have had plants of this four feet high, and as much in diameter, covered with blossom during the late summer and autumn. Its one drawback is that it is usually late coming into flower—mid August or later—as it makes vigorous, though slow, growth all through the earlier part of the summer. Florists' varieties of the fuchsia are endless, many of them differing in little but name.

ALGER PETTS.

Phlox Comtesse de Jarnac.—This phlox is remarkable for the manner in which the leaves are clearly and freely variegated with white. As a flowering plant it does not rank with many of the green-leaved varieties, but its variegation is very constant. It is decidedly a weak grower, and one that cannot be depended upon to hold its own in a mixed collection of herbaceous plants. At Hampton Court it formed during the summer a very pretty bed. The surface of the bed was planted with bright red Begonia Comte Zeppelin, carpeted with Koniga maritima, while as dot plants this phlox was used.—W. T.

MIXED BORDERS.

For providing a display of bloom during spring, summer, and autumn, there is nothing better than a well-furnished mixed border, the term mixed meaning a border which may be utilised for the cultivation of plants of perennial, biennial, and annual duration. Such a border, when carefully planted, is highly appreciated, but it must in no way be confused with the herbaceous border proper.

The difference between the two classes of borders is clearly marked, for whilst the herbaceous must remain undisturbed until the usual replanting and renovation, the mixed border has to be replenished from time to time during the season. Of course, the maintenance of the mixed border in good condition entails a certain amount of additional work, for which one is amply repaid. Various annuals and biennials have to be raised from seeds, and demand attention from the time of sowing until they finish flowering.

The foundation must be herbaceous plants, for one cannot dispense with Michaelmas daisies, helianthuses, delphiniums, phloxes, etc., for the back rows, and various others suitable for the centre and front. The width of such borders depends a great deal on the space at one's disposal. Usually they are too narrow to allow proper planting, and a somewhat cramped appearance is the result. To create a good effect a width of from ten to fifteen feet is required, which will provide ample scope for the exercise of taste in the arrangement. The formation of the front should be of irregular design, with an approach of a wide turf belt or lawn. If the background is to be formed with shrubs, gross feeding kinds should be avoided, otherwise the borders will be robbed of much of the food they contain. Apart from shrubs, an effective background may be provided by using rustic poles, connecting them with a double row of chains to accommodate climbers. The arrangements should be carefully thought out beforehand, and a rough plan or sketch will be found extremely useful in carrying out the work. The back groups may consist of delphiniums, foxgloves, helianthuses, heleniums, the tallest Michaelmas daisies, verbascums, and others of similar habit of growth. Clumps of Anchusa intalica, Opal or Dropmore varieties, are very effective, but they must be removed from the delphiniums. To take the place of the foxgloves or verbascums when their flowering season is over, we have sweet peas and dahlias, also hollyhocks. The sweet peas should be grown on in pots expressly for this purpose. There are usually some plants left over from the main planting, and if shifted into nine-inch pots they will make fine specimens for filling up the gaps.

For the centre of the border there are numbers of plants suitable, such as the dwarfer-growing Michaelmas daisies, and the pæonies, doronicums, phloxes, Dicentra spectabilis, Campanula persicifolia, Canterbury Bells, aquilegias, Chrysanthemum maximum Mrs. Lothian Bell, Oriental poppies, Lobelia cardinalis, pentstemons, Coreopsis grandiflora, and many others. Early-flowering chrysanthemums provide splendid material for refilling the space caused by the removal of the Canterbury bells, also Salvia patens and S. splendens var. Pride of Zurich or Fireball answer for the same purpose. The pyrethrums lift readily and safely immediately after flowering, when the gap is made good with other plants, such as coreopsis, salpiglossus, scabious mallows, etc. Gladioli can be planted between the aquilegias, thus providing a display when the latter are finished.

The antirrhinums are excellent for the summer effect, the tall varieties are suitable for the centre groups, and the intermediate and dwarf types should be planted nearer the front, according to their respective heights. For associating with the antirrhinums we have Sweet Williams, of which some of the improved varieties provide a brilliant show of bloom. Wallflowers should be extensively used for the early spring display, and when their flowering season is over they are cleared off, and the ground planted with either of the two mentioned above. Coming to the edge of the border, and the various plants which will give the best results for the whole season, we have myosotis, polyanthuses, pansies, silenes, arabis, alyssum, and violas. All these should be planted in irregular patches or drifts. Between these may be grown pinks, Campanula turbinata, and C. carpatica, Œnothera taraxacifolia, Œ. macrocarpa, Dactylis glomerata elegantissima, Aster alpinus and its varieties, Iceland poppies, Phlox canadensis, and Thalictrum adiantifolium. Annuals must be grown on for refilling the spaces caused by the removal of the early-flowering spring plants, and here may be mentioned as suitable Dimorphotheca aurantiaca, phloxes, asters, nasturtiums, verbenas, ten-week stocks, French marigolds, leptosiphons, and others of similar habit.

There are many bulbous plants that can be used to advantage, such as English and Spanish iris, various liliums, narcissus, tulips, early flowering as well as late, gladioli, and many others in large variety. The plants mentioned in this note in no way exhaust the list of suitable subjects for the mixed border scheme.

E. C. Pooley.

ANEMONE ST. BRIGID.

Both for the supply of cut flowers, and also for the embellishment of the flower borders, these anemones are becoming more and more appreciated every year. The roots may be planted from the middle of October to the corresponding period of the month following.

An ordinary garden soil will be good enough to grow plants and flowers of ordinary merit. But if the soil be well enriched with rotted manure, and well prepared, the plants and flowers will be of larger size. For a number of years I have grown these anemones rather extensively, and am quite convinced that they are worth all the trouble that the cultivator can give them in the way of good culture.

When they are grown in rows in large beds the cultivator has a good opportunity to thoroughly prepare the ground for the roots. The soil should be of a medium to light nature and well drained, then almost any aspect will do, but I find that the colours of the blooms are richest on plants grown in borders facing the west. Dig the soil to a depth of quite 20 inches, and mix the rotted manure with it, so as to leave the top 4in. of soil free from manure. This is done so as to prevent the roots coming into direct contact with the later before fairly active growth commences in the spring. Having duly prepared the beds draw out drills 3in. deep and 15in. apart. Plant the roots at least 6in. asunder in the rows, and bury them 2in. deep. Do not tread on the beds after planting is finished. In well-drained soil few roots fail, and the leaves grow larger and of good form. Where planted in clumps in borders the soil should be deeply dug and manured, as in the case of large beds.

Geo. Garner.

PEAR DOYNNE DU COMICE.

A great deal has been said and written concerning the merits of Doyenne du Comice pear, but however much praise has been bestowed upon the variety, it has been well merited, for practically every cultivator of hardy fruits is ready to affirm that Doyenne du Comice holds a position among pears, such as Cox's Orange Pippin holds among dessert apples. In each instance, however, the merits of the fruits were not quickly recognised. During the year now drawing to a close very many dishes of splendid fruits of Doyenne du Comice have been staged at the leading exhibitions, and though everyone admires the skill that can produce such wonderful specimens, the huge fruits do suggest the possible need of standard of limitations such as exist in the case of dessert apples.

The accompanying illustration represents one of several fine examples of this delicious pear staged at the great Fruit Show in London a few weeks ago by the King's Acre Nursery Company, Hereford. The flavour if Doyenne du Comice is not only delicious, but unique among pears. November is the month during which this pear is at its best, but fruits often ripen earlier and some keep good later, according to site and season.

Doyenne du Comice is a free-bearing variety, and of excellent constitution, thriving as a pyramid or cordon. It was raised in the garden of the Comice Horticole, at Angers, and the original tree first fruited in 1849. The late Mr. R. D. Blackmore, the novelist, who grew a large collection of pears at Teddington, and gave not a few of the varieties a bad character that has been redeemed by more extensive and skilful cultivation, said of Doyenne du Comice, "This is, to my mind, the best of all pears; very healthy, a certain cropper, of beautiful growth, and surpassing flavour. I have grown it to the weight of 14oz., on heavily-cropped trees. But on a wall it is far inferior." The last sentence is difficult to understand, because experience proves that the variety is an excellent one under every form of good cultivation, and it deserves even wider popularity than it has already attained.

PEAR DOYENNE DU COMICE.

One of several fine fruits recently exhibited by the King's Acre Nursery Company, Hereford.

Packing Fruit, etc.—The proper mode of packing fruit and vegetables for market is fully described and illustrated in the Gold Medal Essay of the Worshipful Company of Fruiterers, entitled Packing and Selling Fruit and Vegetables. Price 1s. from booksellers, or 1s. 3d. by post from Gardeners' Magazine Office, 148, Aldersgate Street, London.

WORK FOR THE WEEK.

ORCHIDS.

CYMBIDIUMS.—Such species as C. Traceyanum and C. Lowianum are exceedingly useful for decorative purposes. The former produces its flowers during the winter and early spring, and it lasts in perfection for several weeks; so that well-flowered specimens make an attractive display, and where the plants are grown under cool conditions, they take no harm if removed to the dwelling house for a little while, providing no gas is used, and they are out of reach of frosts. The flowers last a long time when cut. This cymbidium does not often flower freely as large specimens, and especially is this the case where the plants are grown too warm; the temperature of the odontoglossum house meets the requirements of C. Traceyanum best. The flower scapes will now be advancing from the base of the pseudo-bulbs, and may frequently be mistaken for growths. When they are seen they must have every encouragement, but care should be observed not to overwater during the winter. Saturation at the roots during low temperatures is the forerunner of black spot.

CYMBIDIUM LOWIANUM flowers later in the spring than C. Traceyanum, and where grown under favourable conditions there is no orchid more useful or that gives a more satisfactory return of flowers. Well-grown plants of this species in its different varieties are prominent subjects in our spring and early summer exhibitions. The flowers last for months in perfection if placed in a cool house, while when cut there are no flowers that I am acquainted with that have so great durability. The flower scapes in some cases make their appearance about the present season, but where the plants are grown with the odontoglossums, the remarks given in connection with C. Traceyanum will apply. If the plants are not overwatered they will grow far more satisfactorily under cool conditions than when grown in the intermediate house.

HYBRIDS.—The numerous hybrids that are now procurable for a modest outlay have added interest to the culture of cymbidiums. C. Lowio-eburneum is perhaps one of the most variable and desirable among them. It does best when grown with the above-named species, producing flowers during the spring months. C. Wiganeanum, C. Winnianum, C. Low-grinum, C. I'Ansoni, C. Holfordi, the secondary hybrid C. Colmanæ, and others, are all worthy of cultivation, and they may all be grown under cool conditions. Where a house can be devoted to cymbidiums there is little difficulty in keeping the plants clean and free from red spider by syringing the foliage whenever the outside conditions permit; but where grown under warm conditions, with other plants, they need constant observation to keep this pest in check during the winter months. Sponging with a weak solution of soft soap is the best remedy. Potting should not be too frequently done, but, when needed, good lasting material and ample drainage should be used.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

BOUGAINVILLEAS. — Specimens that have been subjected to a thorough ripening of their wood may now be transferred to a cool position, and the cooler their surroundings, so long as they do not suffer from frost, the better will be the resting period the plants will enjoy. This is important, as plants start better next season thoroughly rested, and will then produce abundance of strong, healthy shoots.

GLOXINIAS.—Extreme care must now be exercised with autumn-raised seedlings, and they should be afforded a light position near the glass in order to ensure that sturdy foliage, which is so essential for future success. A minimum temperature of 65 degrees will suffice to secure a steady growth throughout the winter. Unless the position and locality are most favourable, potting should be deferred until the New Year. A selection of the earliest ripened corms may now be made for the earliest of next season's stock. I prefer to allow the old corms to remain undisturbed in their flowering pots; being placed on a shelf in the stove, very little attention is necessary until growth appears to be making progress, when watering with diluted farmyard liquid and clear soot water is allowed. Excessive applications may soon cause serious damage during winter months.

ALOCASIAS.—A. Sanderiana succeeds best when kept steadily growing throughout the winter, and ought not to be ripened off so severely as some other of these valuable and extremely useful fine foliage plants. The general stock have now completed their growth, and are ready for resting; gradually reduce the supply of water at the roots until the foliage has completely died away, and then keep them dry at the roots and store in a dry position in the stove.

GENERAL REMARKS.—Now that the winter season is almost with us, nearly all potting operations must be stopped for the remainder of the year. Attention, however, must be directed towards renewing the annual supply of potting material. Some best quality fibrous loam must be secured and stocked with the grass side downwards. A sprinkling of lime and soot between each layer destroys insects and discourages wireworms and similar pests. Securing leaves for a supply of leaf-mould as an item easily overlooked, and the consequence is leaf-mould of an inferior grade. Clean leaves of beech and oak should be selected, but they must be kept free from insect life, grass, and other matter. As a general rule, leaves do not become decomposed sufficiently for potting until they have been stacked up for a year or so and turned over once or twice. All old flower pots not in use should be washed, placed in their sizes, and stored away safely until they are wanted in the busy season; broken pots intended for drainage may also be similarly treated, and this work, if carried out as circumstances permit, will save time and confusion during the busier season. —John Donoghue, Bardon Hill Gardens.

FRUITS UNDER GLASS.

EARLY GRAPES.—Preparation for forcing should now be set about in earnest if ripe grapes are expected by the end of next April or early in May. The vines may now be pruned back to two eyes. In the case of pot vines, scrub the pots, and see that the drainage is secure, then they will be ready for the forcing pit. A lean-to structure facing south will be the best position, and a pit which is half underground and can be kept warm during the dull days will be found to answer the purpose admirably. Place the pots about 2ft. from the glass, and see that the base of each pot is on a firm footing, the space around being filled with dry tree leaves which will give a little bottom heat to start the roots, and be better for the vines than fire heat. Tie the rods down to secure an equal break, and close the house, keeping the temperature at about 50 to 55 degrees for the first three weeks. Much care will be required in watering, as it must be remembered that very little water will be needed until growth commences; on the other hand, the soil must not become dry. On fine days spray with tepid water the rods and pots. The best varieties to force in this way are Black Hamburgh and Foster's Seedling, these two setting well in dull weather. Early vines in permanent borders will need treatment very similar to that recommended for pot vines, and if made ready to start by the beginning of December, will make a good succession. It is assumed that the rods have had a good washing, so that they are absolutely clean and free from pests.

FIG HOUSE.—As soon as all the leaves have fallen, the trees should be pruned. These need pruning hard, as the branches must not be too thickly placed or there will not be room for the foliage to develop properly. Take out as much wood as possible from the base, even at some sacrifice for one year, and encourage young, short-jointed growths, as it is from these we have the best results; then proceed to tie up the branches in bundles for convenience of cleaning wires, glass, and walls. Clean every part of the house with soft soap and a strong insecticide, and finally wash the walls with hot lime, to which add petroleum and sulphur. If the figs are at all dirty, clean them, and finally tie into position again. All the strongest shoots should be tied with tarred string. Then clean the borders and staging, rake off all old top-dressings, and, if necessary, top-dress with some fresh loam and lime rubble, making this firm with wooden rammers.

CHERRY HOUSE.—Proceed to clean the trees and structure as in the case of the fig house. Most of the pruning should have been done, as cherry trees are not fond of the knife. All old, worn-out growth must be carefully cut away, and the trees thoroughly cleansed.

TOMATOES.—Keep the house airy, with a little fire heat. Tomatoes are now growing splendidly. Successional batches should be potted and placed on a shelf where they can obtain the benefit of all possible light in order to keep them sturdy. Gather the fruits from the fruiting plants as soon as ready.

STRAWBERRIES IN POTS.—Place these under cover in cold frames, or they will become too wet. Select the best crowns for forcing next month. — W. A. Cook, Leonardslee Gardens.

THE FLOWER GARDEN.

PLANTING.—The work of planting should proceed at every available opportunity, bearing in mind the fact that autumn planting is considerably more conducive to the future welfare of the shrubs than spring planting, especially when dealing with deciduous subjects. It is important that the soil should be made firm, and therefore it is necessary it should be in really good working condition, that is, it must not be too wet and sticky otherwise it cannot be made firm. Any subject likely to be shaken about by the winds should be securely staked and tied. The style of planting rests entirely with individual tastes; some prefer grouping, while others are in favour of dotting plants about singly. Undoubtedly many shrubs are seen to best advantage when grouped, notably many flowering and foliage plants, such as berberis, cytisus, prunus, gorse, golden elder, variegated dogwood, and others. Space here does not allow a long list of trees and shrubs, yet mention may be made of a few which should not be overlooked. The tulip tree (Liriodendron tulipifera) does not appear to be as popular as it should be, and not nearly so extensively planted as it deserves. It is a beautiful object when in flower, and in the autumn, with its changing tints of green and yellow, is very conspicuous. It should be treated as a specimen, and planted in close proximity to the liquid amber, which has a grand colour in autumn. Parrotia persica is by no means common, yet its foliage is decidedly attractive late in the season. The deciduous cypress (Taxodium distichum) thrives remarkably in damp places, the banks of a lake or pond suiting it wonderfully well. There are some splendid varieties among the oaks, such as Q. coccinea (scarlet oak), Q. Mirbecki, Q. coccifera, Q. nigra, Q. Damie, Q. conferta, Q. rubra, and others.

LILY OF THE VALLEY.—The beds should be top-dressed with well-decayed leaves as soon as the foliage has ripened. The plants derive great benefit from this material, and make excellent growth when this plan is carried out annually. Lily of the valley should be lifted every three or four years, otherwise the beds become overcrowded, and small, inferior spikes of bloom result. Where necessary, this work should be attended to at once, replanting the crowns singly. The best results are obtained by planting in a deep, rich material, which has a good quantity of leaf-soil thoroughly incorporated with it, top-dressing with the latter material when planting is completed.—E. C. Pooley.

EXHIBITIONS AND MEETINGS.

◆

Bournemouth.

OCTOBER 31 and NOVEMBER 1.

The twenty-fifth annual exhibition of autumn flowers, fruit, and vegetables was held in the spacious Winter Gardens on the above dates, and proved to be a great success. Never before has the competition been so keen, or the quality of the exhibits equalled. The committee and officers are to be highly congratulated on having arranged such a splendid exhibition. Some exhibitors came as far away as from the north midlands. Cut chrysanthemums, groups, orchids, grapes, apples, carnations, and displays of vegetables were the principal features. Sir Trevor Lawrence, Bart., K.C.V.O., opened the exhibition, and made many very favourable comments on its excellence.

GROUPS.

In the class for a group of miscellaneous plants and cut flowers, Mr. Usher, gardener to Sir Randolph Baker, Bart., won chief honours, having very fine chrysanthemums and well-coloured crotons; The Parks Nurseries, Lim. (Mr. F. W. Welch), Bournemouth, came a very close second; and Mr. W. Evans, gardener to G. J. Fenwick, Esq., a creditable third. For a group of decorative and single chrysanthemums, Mr. Evans won first position; Mr. C. Pearce, gardener to Mrs. Ormond, was second with a charming group; Mr. Usher being third. The silver cup presented by the Dowager Lady Miller for a group of chrysanthemums was won by Mr. Cox, gardener to G. F. Duberly, Esq.

CUT BLOOMS, ETC.

There were five entries in the class for twenty-four blooms, distinct, on boards, and Mr. Woolman, Shirley, Birmingham, led with fine specimens, the following being noteworthy, namely, Dreadnought, Beecham Keeling, Mary Farnworth, S. F. Richardson, Rose Pockett, Mrs. David Syme, Thomas Figg, Mrs. L. Thorn, Mrs. A. T. Miller, Mrs. Lopes, Master David, Kara Dow, Francis Joliffe, Eclipse, and Evangeline; Mr. J. R. Tooley, gardener to Hugh Andrews, Esq., Winchcombe, was a close second, Eclipse, Pockett's Crimson, Edith Jameson, Purity, and W. Beadle being the best blooms; third honours went to Mr. Usher. In the class for nine vases of Japanese blooms, three blooms of each, distinct varieties, Mr. Woolman was first, followed by Messrs. J. R. Tooley and Mr. Usher for second and third honours respectively. The best blooms in the show were staged in this class, and the variety, Francis Joliffe, stood out well ahead of all others. Lady Talbot and the Hon. Mrs. Lopes were also exceptionally good. The stands of Japanese incurved varieties were excellent. Mr. Usher again led with Miss A. Nicolls (2), Lady Edward Letchworth, F. Penford (2), W. Rawlings, George Mileham '08, F. W. Lever, W. Jinks, Mdm. G. Rivol, and Lilian Hall; Mr. J. R. Tooley, and Mr. G. Barge, gardener to Rev. C. H. Burrows, Bournemouth, were second and third respectively. Mr. Cox won the silver cup presented by Mrs. Caroline Pelfer for two vases of Japanese chrysanthemums, two distinct varieties, nine blooms in each vase; Mr. Tompkins, gardener to the Dowager Lady Miller, second.

Bush plants were well shown, Mr. C. Barrett, gardener to C. Howard May, Esq., was a prominent prizewinner. Mr. Usher won the cup offered for a group of cut blooms of carnations on a base of fern; Mr. Fay, Southampton, came second. In the class for six vases of carnations, these two competitors won in the reverse order.

FRUITS AND VEGETABLES.

Nearly sixty bunches of grapes were staged. The quality was good, and competition keen. Mr. Carter, gardener to R. Neville Grenville, Esq., Butleigh Court, was first in the class for three bunches, distinct varieties; Messrs. J. R. Tooley and George Garner being second and third respectively. Mr. Garner was first in the open class for two bunches of black grapes; Mr. Hill, gardener to Mrs. Banks, Kingston Lacey, second; and Mr. C. Barrett third. Mr. Pope, gardener to G. R. Pike, Esq., had the best two bunches of white grapes in the open class, and also in the local one. Mr. Tooley came second, and Mr. Foskett third. Mr. Garner was second in the local class for two bunches of white, and Mr. Foskett third. Mr. C. Barrett was first in the corresponding class for two bunches of black grapes; Messrs. Garner and Steptoe second and third respectively.

Apples made a grand show. Mr. Cape, Wimborne, had the best four dishes of kitchen apples; Mr. Hill was first with four lovely lots of dessert apples; Mr. Douche had the best two dishes of dessert; and Mr. Gould the best two dishes of kitchen apples.

Vegetables were clean and good, and well represented. Mr. Usher won the principal prize for collections.

NON-COMPETITIVE EXHIBITS.

Gold medals were awarded to Messrs. D. Stewart, Wimborne, for apples and pears; Messrs. Sutton and Sons, for vegetables; Messrs. Charlesworth and Co., for orchids; and to Messrs. Mansell and Hatcher, for orchids.

Silver medals were granted to Mr. T. K. Ingram, for miscellaneous plants; to Messrs. Jessie Kent and R. Chamberlain, for floral designs; to Hummerford Nurseries, Lim., for cut flowers and floral designs; to Messrs. Toogood and Sons, for vegetables; to Mr. Ed. V. Low, for orchids.

Mr. Slade was highly commended for zonal pelargoniums.

Torquay Gardeners' Association.

The annual show of the above association was held on November 3 in the large hall of the Bath Saloons, Torquay, and proved a very successful exhibition. More entries were received than at any of the former shows, and the plants and flowers staged were of exceptional merit, while the competition was so close that in many cases the judges found it very difficult to select the winner. The competition for the groups of single chrysanthemums was very keen, the first prize and the National Chrysanthemum Society's Certificate of Merit being awarded to Mrs. Lyon for a magnificent group. The first prize for a group of large-flowered chrysanthemums was won by Mrs. Richardson with a splendid collection of flowers, many of which would not have been out of place on the show board. A silver cup was given to artizans and cottagers for six cut chrysanthemum blooms of any variety, and was won by Mr. T. Guest, who also beat all comers in the open classes by carrying off the National Chrysanthemum Society's silver medal for the best bloom in the show, a magnificent specimen of the pure white Mrs. A. T. Miller, this victory reflecting the greatest credit on an artizan. The specimen plants were enormous.

The leading prize-winners were as follows: For twenty-four Japanese cut blooms, Dr. T. G. Skardon; for twelve Japanese cut blooms, Dr. T. G. Skardon; for a collection of vegetables, Mr. P. P. Alexander; for a collection of apples, Mr. P. P. Alexander; for a collection of pears, Mr. P. P. Alexander; for a dinner-table decoration, Mr. F. Perrett; for an epergne of cut chrysanthemums, Mr. W. H. Samerell; for a group of chrysanthemums in form of a semi-circle, Mrs. Richardson; for a group of single chrysanthemums, Mrs. Lyon; for three trained chrysanthemums, singles, Mrs. Lyon; for three trained chrysanthemums, doubles, Mrs. Lyon; for six table plants, flowering, Colonel Cary; for six table plants, foliage, Dr. Quick; for three table plants, flowering, Mrs. Tottenham; for three table plants, foliage, Mrs. Tottenham; for six ferns, Colonel Cary; for winter-flowering begonias, Captain Phillpotts; and for three solanums, Dr. Quick.

There were several classes confined to residents in the borough, and all but one of the first prizes for cut blooms were won by Mrs. Lyon. The solitary other first prize-winner being Mrs. Tottenham. Mr. W. H. Prowse led for a basket of berried plants. In the classes for vegetables open to amateurs the majority of the first prizes were won by Colonel Cary, and in the fruit classes Colonel Cary was also most successful. In the special prizes for vegetables Mr. P. P. Alexander was to the fore.

The nurserymen's exhibits aided considerably to the beautifying of the show. The Devon Rosery Company, Torquay, staged a fine collection of plants, including Eupatorium micranthum (Weinmannianum), Acalypha hispida, Lilium longiflorum grandiflorum, Nerine Bowdeni, Cyclamen persicum, Bouvardias scarlet, white, and pink, Solanum capsicastrum, Erica hyemalis, etc., Pandanus Veitchi, a fine collection of chrysanthemums, some handsome palms arranged at the back, and maidenhair and other ferns. The same firm made a splendid display of fruit, the apples and pears being of the highest quality and nearly a hundred dishes being staged. Many of the fruits were far more highly coloured than usual, Bramley's Seedling, of which some enormous fruits were shown, being especially noticeable in this respect. Bismarck was also very fine and large, as was Peasgood's Nonsuch, and Cox's Orange Pippin were extraordinarily large and highly coloured, while of the many varieties of pears exhibited the peerless Doyenne du Comice proved a great attraction.

Messrs. Robert Veitch and Son, Exeter, contributed a most interesting stand, containing a large number of winter-flowering carnations in full bloom. A few of the varieties were Rose Doré, May Day, Mikado, White Perfection, Lady Audley Neeld, Scarlet Glow, Imperial, Winsor, Carola, Rival, Lady Dainty, White House, Colossus, J. W. Riley, Rex, Mrs. C. F. Raphael, Lady Alington, J. W. Riley, and Sarah A. Hill. Among the other plants shown were Acacia Baileyana, Metrosideros floribunda, which is the nurseryman's name for Callistemon salignus, Rhus copallina with deep crimson leaves, Berberis Thunbergi, scarlet foliage; Aster grandiflorus, the largest flowered of all the Michaelmas daisies, but too late for any not living in the south-west; long crimson fruits of the rare climber Thladiantha dubia, said to be found in India and China, Pancratium macrostephana, Nerine Fothergilli major, Quercus coccinea, Correa cardinalis, and C. magnifica.

Others who contributed attractive stands were Mr. W. B. Smale, Torquay, who showed the variegated variety of Phormium tenax, zonal pelargoniums, and many other plants; Mr. H. Mayne, Torquay; and Messrs. Burridge and Sons, Torquay.

Lee and Blackheath Horticultural Society.

On Friday, October 27, at the Church Street Schools, Lee, Mr. T. W. Sanders gave a lecture on "Up-to-date Gardening." This was the first of a series of lectures for the winter session organised by this society.

One of the things necessary to obtain the best results from the garden, the lecturer said, was a thorough knowledge of the soil dealt with, while the constituents of the manures used should be understood in order that they might be intelligently applied. Chemical manures were at the present day an absolute essential factor in successful gardening owing to the scarcity of farmyard manures, and also to the fact that the ground is impoverished by continual cropping.

Winter spraying of fruit trees was dealt with pretty fully by the lecturer, and he described the best washes for the different purposes, the time to use them, and the most up-to-date methods of distributing them on the trees.

Portsmouth. NOVEMBER 1, 2, and 3.

The annual exhibition was held in the Town Hall—an excellent site—and was quite a success. Groups of chrysanthemums were a strong feature, being both numerous and good. Cut blooms were not plentiful, but in point of quality quite up to the average. Fruit was a strong feature, apples especially. The management was of the best under the careful guidance of Mr. W. E. Gill, hon. secretary, and a strong committee.

CUT BLOOMS.

There were five open classes, the principal one being for thirty-six Japanese in not less than eighteen varieties, not more than two of any one variety. A silver challenge cup, value £20, with a cash prize of £5, were offered as the premier award. Mr. Baxter, gardener to Captain Dalgety, Lockerley Hall, Romsey, occupied the post of honour with a set of high-quality blooms, well staged. The following were the most noteworthy: The Hon. Mrs. Dalgety, an improved Master James, Frances Joliffe, Mrs. E. Herring, Lady Talbot, Master Joiffe, Bessie Godfrey, Madame P. Radaelli, Hon. Mrs. Lopes, Eclipse, Mrs. K. Stoop, J. H. Silsbury, R. Vallis, D. B. Crane, Mrs. A. T. Miller, and W. Mease. Mr. Hunt, gardener to P. Ralli, Esq., Ashtead Park, Epsom, was a good second with an uneven set; Lady Letchworth (extremely fine), Alice Lewis, Mrs. A. T. Miller, Evangeline, and Miss A. Nicoll were the best.

The prizes for two dozen Japanese, in not less than twelve varieties, and not more than two of any one variety, produced keen competition. Mr. A. Herbert, gardener to Sir F. Fitzwygram, Leigh Park, Havant, secured the leading award with an even lot of blooms. Especially good were Duchess of Sutherland, Countess of Granard, W. Biddle, and Mrs. A. T. Miller. W. E. Gill, Esq., Osborne Road, Southsea, was a capital second, with a well-balanced set, lacking size only. Mr. T. West, gardener to R. W. Foster, Esq., Stubbington, Fareham, third.

Incurved blooms were remarkably good considering the early date. Mr. Hunt occupied the premier position for twenty-four in not less than twelve varieties, with really fine examples of Buttercup, Romance, W. Biddle, H. W. Thorp, Edwin Thorp, Clara Wells, Duchess of Fife, John Wainwright, and Embleme Poitevine, all, neatly staged Mr. Gill was second.

Single-flowered varieties have for many years being remarkably well shown here, and there was no exception this season. Mr. H. Snook, 5, Fitzroy Street, Portsmouth, won for twelve sprays, three blooms of each variety, with a handsome collection, including such varieties as Malta, Ideal, Wm. Rogers, Draco, Sylvia Slade, and Caledonia. Mr. C. Johnson, 10, Garnier Street, Portsmouth, second. Pompone varieties are here usually well shown in bunches of three. Mr. Snook again won first place with typical blooms of W. Westlake, W. Sabey, and Rosinante. Mr. J. Vance, 98, Hampshire Street, Portsmouth, second.

In the classes in which the competition was limited to Portsea Island, Mr. Gill won for incurved and Japanese, also with commendable blooms. An interesting class was that for one dozen incurved and as many Japanese, confined to a radius of twelve miles. Mr. D. Edwards, gardener to W. Garton, Esq., Salisbury Court, was easily first with some of the finest blooms of popular varieties in the show; Mr. Gill second.

PLANTS.

Six competed in the class for a group of chrysanthemums in pots, on a space of 60 square feet. Mr. W. E. Gill was first with dwarf plants, well clothed with healthy leaves and carrying really good blooms, neatly arranged. Mr. Herbert second. Miscellaneous plants, arranged for effect, in combination with quality, were not numerous, but added to the interest of the show. Mr. W. Rooke, gardener to Sir J. Brickwood, Esplanade Hotel, was first; Mr. Papworth, gardener to the Parks Committee, Portsmouth, second. Mr. Lambert, Chichester, had the best twelve specimen chrysanthemums, and also the finest eight plants, staging well-grown varieties.

FRUIT AND VEGETABLES.

These were excellent. Mr. Ellwood, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, was first for two bunches of black grapes and for six dishes of apples, and also first for collections of vegetables, in classes where the prizes were provided by Messrs. Sutton, Webb, and Toogood. Mr. Baxter won for white grapes, and Mr. C. H. House, Privett, Gosport, for a collection of pears.

A gold medal was awarded to the Barnham Nursery Company for a collection of apples of exceptional colour, Golden Noble, Newton Wonder, Gascoigne's Seedling, Bramley's Barnack Beauty, Bowhill Pippin, King's Acre Pippin, and Allington Pippin were the leading dishes. A silver medal was awarded to Messrs. W. Wells and Co., Merstham, for a collection of new chrysanthemums; Gertrude Peers, Mrs. W. Hookey, Mrs. W. Gilbert Drabble, and Mrs. P. A. Witty were noteworthy here as new Japanese varieties. Dorothy Dan, a very pretty bronze-amber, medium-sized single chrysanthemums, was also worthy of note.

Chrysanthemum Show and Conference at Biarritz.

On the occasion of the sixteenth annual congress of the French Chrysanthemum Society an international show of chrysanthemums, fruit, etc., was held in the Casino at Biarritz. It was opened on the 26th ult. and closed on the 29th. In conjunction with the Golf Society of Gascony and the Bayonne Horticultural Society a most attractive show was organised. The beautifully decorated rooms of the Casino formed a splendid setting for the show, the walls and ceilings being richly decorated, as many of our readers may know. The weather, unfortunately, was not "King's weather," but the show was well attended. There were forty classes in the schedule, chrysanthemums predominating.

The international jury was presided over by M. H. Martinet and M. Blot, both of Paris. Vice-presidents were Mr. Harman Payne and Senor de la Pena. The secretary of the jury was M. Ph. Rivoiré. The Casino is approached through an iron railing, inside which is an attractive garden planted with carpet bedding and ornamental shrubs in tubs. The visitor then passes into the vestibule, and from the top of the handsome flight of stone steps a fine view of the show is obtained so far as the central corridor is concerned. Then right and left are various halls filled with the products of the various exhibitors; a wonderful contrast to anything we have seen at our own provincial shows. Perfect taste prevails, but of course in a general way the individual exhibits would not reach the high standard observable "chez nous." M. Rodrigues, the devoted and genial president of the Golf Society, and a most enthusiastic chrysanthemumist, warmly welcomed us, and indeed during the whole of the festivities we were deeply indebted to him for the great enjoyment provided.

The grand prix d'honneur goes to Messrs. Vilmorin, of Paris, for a room full of chrysanthemums staged in their well-known style. There were two large groups, mostly bush and trained standards, enclosed in a border edging of dwarf plants of Gerbe d'Or and Purpurine, a fine display, of which much more might be said. The next prix d'honneur was carried off by Messrs. Gelos, the Biarritz florists, assisted by Mme. Bégue. In one large, handsomely-decorated saloon, covered with carpet, they staged floral decorations. In the middle was a table set out for a wedding breakfast in rich style, white roses being the chief "motif." Around this were thirteen other little circular tables, lamp shades, table covers, etc., being all of the same shade as the flowers employed for the decorations; a truly delicate series of floral compositions.

M. Rodrigues staged a handsome group of chrysanthemums in pots, for which he well deserved the third prix d'honneur.

There was special provision made for new seedlings, and a good number of entries. Prizes of honour were awarded to Messrs. Calvat and Chantrieu. Medals and diplomas to Messrs. Dolbois, Lacroix, Heraud, and others. Trained plants in infinite variety, as is now the custom in France, were staged. Groups of plants and cut blooms were well shown by Messrs. Roumagnac, Calros-Géraud, pieuchot, Loublié, Lassus, Bonnet, and others.

Without particularising we may say that the best flowers in the show appeared to be Ant. Marmontel, Australie, Lieut.-Colonel Ducroisèt, Bryant's Beauty, Ma. Provence, Alphonso XIII., Mrs. C. H. Totty, Sapho, Miss Dalton, Mr. R. F. Felton, Lady Hopetoun, Ferd. de Bièvre, Paul Randet, and a few others mainly of French origin, and not known on this side of the Channel.

Throughout the show there were a great many exhibits in the section for floral art. These all came from Messrs. Gelos Frères.

Dahlias were numerous, and rather better done than we have seen before. M. Rodrigues had a large collection, at the end of which was also a display of cut roses. Dahlias were also shown by Messrs. Lavasse, by M. Loublié, etc.

Miscellaneous exhibits were not numerous. A nice bank of ferns, Nephrolepsis in variety, was set up by M. Roumagnac, who was a very prominent exhibitor in other sections. M. Lassus showed a decorative group of Begonia Rex, and M. Lassus also sent a nice lot of Begonia pictavensis. Messrs. Labaste had a good collection of carnations, neatly decorated with pots of maidenhair ferns.

Fruit and vegetables were provided for by the schedule, but the entries were limited. We should, however, mention, as exhibitors, Mme. Julien, Cte. de Bearn, and the Prorieté Tourneau.

The sixteenth congress of the French Chrysanthemum Society was held in conjunction with the show at Biarritz, and a most enjoyable function it was throughout.

On the first day (October 26), the jury met at the show, and proceeded to make the awards, after which they were entertained to lunch at the Grand Hotel by the organising societies. M. Martinet, as president of the society, presided. The show was officially opened at 2.30, when the band played, out of compliment to the visitors the English and Spanish National Anthems, and the Marseillaise. At 4 p.m. there was a reception by the Mayor of Biarritz of the members of the congress, champagne and light refreshments being handed round.

On the second day, at 9 a.m., M. Viger presided at the first meeting of the congress, being supported by all the officials on the platform.

The first paper to be read was one by M. Blot, which discussed very fully the necessity for the society, publishing a pocket edition of the Repertoire des Couleurs. His plan is a good one, for it must be evident to everyone that in its present form the work is only useful in the office or library, and cannot be carried about in the garden and greenhouse for use. M. Blot proposes a new arrangement of the colours, and that they be printed on grey paper instead of white. Messrs. Oberthur and Clement expressed approval. It was resolved that the same be carried out. The other questions were of less interest to our readers. M. Decault read a paper on "The Taking of the Bud." Dr. Chifflot discussed "Insects and Diseases." M. A. Crepin called atention to the large number of plants that were non-productive of buds this year. Nearly all his grown in the open suffered.

Mr. Harman Payne stated that, although the chrysanthemum was a hardy plant, yet in America it was grown for show under glass and on benches, mainly because of the different climatic conditions. He thought that this system in hot summers might be useful to French growers. Dr. Chifflot, Mr. Charvet, and others contributed to the discussion. Other papers followed on "Manures," etc. The usual awards were made to the readers of papers, and a proposition was made to hold next year's congress at Nantes.

In the evening a grand banquet was held, when a large company was present. M. Viger presided. Among the speakers were Messrs. Martinet, Rodrigues, the Mayor of Biarritz, Rivoire, Harman Payne, etc.

Saturday, October 28, was a full day. A visit to Hendaye, a newly-laid-out seaside resort, was made, where, at the Hotel Esknalduna. M. Martinet entertained between 70 and 80 guests. The river was crossed in boats, and a visit paid to the old Spanish town of Fuenterrabbia, then a return was made to Hendaye, and the party left by rail for San Sebastian. Among the sights the party visited was the King of Spain's Palace of Miramar. Altogether this was one of the most interesting and enjoyable gatherings the French Chrysanthemum Society has yet organised.

Reading Gardeners' Association.

At the monthly meeting held in the Abbey Hall on Tuesday (by kind permission of Messrs. Sutton and Sons), Mr. Alderman Parfitt presided over the largest attendance of the session. In opening the meeting the President urged the members to do their utmost to make the exhibition to be held under the auspices of the Association an even greater success than in former years.

The lecturer for the evening was Mr. F. Townsend, head gardener to Leonard Sutton, Esq., Hillside, Reading, and his subject was "Hardy Annuals, including Asters and Stocks." Mr. Townsend, as is well known, has no superior in the cultivation of annuals, and the gardens at Hillside always bear witness to his skill as a grower of these charming flowers, which go so far to make our gardens glorious in summer. The lecture was illustrated by a very fine collection of lantern slides, many of them beautifully coloured, and the display of these splendid pictures greatly added to the enjoyment of the large audience. As each picture appeared on the screen Mr. Townsend gave a description of the subject it illustrated, naming the best varieties to grow, and stating, for the benefit of his audience, his method of treatment, which had brought him so much success as a grower of annuals. In the discussion following the paper the lecturer's wide experience was greatly in evidence, the many questions asked being answered promptly.

Certificates for cultural skill were awarded to Mr. H. Wilson, head gardener to Mrs. Bland-Garland, for an exhibit of fruit consisting of a collection of apples and three bunches of grapes; and to Mr. G. Durrant, gardener to Miss Cripps, for chrysanthemums in pots. Mr. W. J. Townsend, head gardener at Sandhurst Lodge, staged some beautifully grown cabbage, Sutton's "Little Gem."

Birmingham Chrysanthemum and Fruit Show.

The fifty-first show held by this society was a grand one from a horticultural standpoint, and, we trust, will prove to be more successful, financially than has been the case in recent years. Tuesday November 7, the opening day, was, unfortunately, rather stormy, but during the afternoon and evening a good crowd of visitors passed the turnstiles. There was a slight falling off in the number of competitive exhibits, especially in the big plant classes, but the trade came forward in goodly numbers. The management, in the same capable hands as for some years past, was excellent in every way, the reputation held by the society for the best-managed chrysanthemum show in the provinces being well maintained.

FIRST-PRIZE EXHIBIT OF EIGHTEEN JAPANESE CHRYSANTHEMUMS.
Staged at Birmingham Chrysanthemum Show by Mr. W. Iggulden, Lock's Hill Nursery, Frome.

PLANTS.

There was a sad falling off in the entries for specimen plants, the half-dozen classes in the schedule finding Mr. Alfred Cryer, gardener to J. Arthur Kenrick, Esq., Barrow Court, Edgbaston, the only exhibitor. His plants throughout were of fine quality, and worthily received first prize in each case. The classes were for six, three, and one plant, Japanese; six and one other large-flowering variety, and three singles. Mr. Cryer again secured chief honours for the large group, arranged on a ground space 16ft. by 10ft., the display being excellent both in point of quality of flowers and tasteful arrangement. Small ferns, crotons, and selaginellas were used in the foreground, and a fine specimen palm occupied the central position. Second prize in this class was taken by Mr. C. Corbett, gardener to Hume C. Pinsent, Esq., Harborne. For a smaller group, occupying 14ft. by 10ft., Mr. Raynor Bullock, gardener to T. W. Piggott, Esq., Lions Park Hill, Moseley, led. His group was light and elegant, with a preponderance of white, mauve, and yellow, just relieved by individual plants of bronze and crimson shades. Silver-leaved centaureas were interspersed between the flowers with good effect. Second prize went to Mr. L. Fewkes, gardener to H. Greene, Esq., Gravely Hill. Mr. C. H. Herbert, Acocks Green, led for a group of decorative varieties putting up an extremely fine group, among which singles and the lighter, feathery varieties were well used Mr. A. Cryer was a good second. Each of the group classes had two entries only.

CUT FLOWERS.

These opened with a class for six vases of Japanese, each containing three blooms, all distinct varieties. Among four entries Mr. W. Iggulden, Locks Hill Nursery, Frome, led with some splendid flowers shown in good condition. D. B. Crane, Master David, Francis Jolliffe, and F. S. Vallis were particularly fine. Mr. Hugh Andrews, Toddington Manor, Winchcombe, was placed second, his set including Master James, R. Vallis, E. Jameson, and Mr. W. Mease, among others. Mr. H. Woolman, Shirley, was third, a grand bloom of Alice Lemon and a good Lady Crisp being noticeable among a nice lot. Fourth prize went to Mr. H. Chandler, gardener to Countess Craven, Ccombe Abbey, Coventry.

Four vases of triplets formed another class of four entries, the winner being Mr. W. H. Westbury, gardener to J. H. Wheatley, Esq., Berkswell Hall, Coventry. His varieties were Mrs. Charles Penfold, Reginald Vallis, Mrs. E. Parson, and Francis Jolliffe. Mr. W. Iggulden came second, again showing remarkably fresh blooms of rare quality. Mr. Hugh Andrews was third, his flowers of Hon. Mrs. Lopes and Lady Talbot being fine. Mr. H. Chandler was fourth.

Single vase classes were provided for three blooms of one variety, in pink, crimson, white, and yellow varieties. Mr. H. Woolman scored for pink with Alice Lemon in splendid form, Mr. W. Iggulden being second with Reginald Vallis; third was taken by Mr. H. Chandler with the same variety; and fourth by Mr. Hugh Andrews with Edith Jameson. Mr. Hugh Andrews led in the class for a crimson variety with a nice three of Pockett's Crimson. Mr. Chandler coming second with Master David; Mr. Iggulden was third with the same variety; and Mr. Jas Shuter, Small Heath, fourth.

The best vase of whites was Mrs. A. T. Miller, shown by Mr. W. H. Westbury; Lieut.-Colonel Beech, Brandon Hall, Coventry, second, with Pockett's White Australia; Mr. Hugh Andrews third with R. H. Marsham; and Mr. W. Iggulden fourth with Annie Hamilton. Lieut.-Colonel Beech had the best yellows, showing F. S. Vallis of rare size, second prize being taken by Mr. W. H. Westbury, third by Mr. Iggulden, and fourth by Mr. Hugh Andrews.

Single chrysanthemums in four vases mustered three entries, the leading prize-winner being Mr. H. Tribe, gardener to F. W. G. Williams, Esq., Bredenbury Court, Bromyard. His flowers were not over-large, but were of good, true single character, not running to three and four rows of petals, as so many present-day varieties do. Second place was taken by Mr. H. Woolman, who showed big bunches of free-flowering kinds, Mr. W. Newton, gardener to Major Everett, J.P., Knowle Hall, obtaining third prize.

Only one entry turned up for four vases containing twelve distinct varieties of incurves, first prize being awarded to Mr. T. W. Davis, gardener to H. F. Keep, Esq., The Grange, Edgbaston. In a similar class, in which competition was limited to Birmingham growers, there were three entries. Mr. Raynor Bullock, gardener to T. W. Piggott, Esq., Moseley, received premier award, his blooms of Romance, Madame Firlat, and Frank Thurston being finely built flowers. Mr. T. W. Davis, gardener to H. F. Keep, Esq., Edgbaston, the second prize-winner, had C. H. Curtis, W. G. Denyers, Mrs. Judson, and others among a well-grown but not quite even set. Mr. A. Cryer was awarded third prize. Half a dozen entries of two vases, each containing three blooms of two distinct varieties, formed another local class, and it was a very good class. Mr. Raynor Bullock led the way, showing Godfrey's Eclipse and Buttercup. The other prizes were secured by Mr. T. W. Davis and Mr. G. Corbett. The local men had a class reserved to themselves for twelve Japanese varieties, distinct, staged in four vases. Three entries found Mr. A. W. Young, gardener to Mrs. R. Peyton, Edgbaston, at the head of the list. He had very good flowers of Lady Talbot, Beecham Keeling, Sir Frank Crisp, and Mrs. A. T. Miller on his stand. Mr. Mark Chatfield, gardener to J. Archdale, Esq., Harborne, won second prize; and Mr. Raynor Bullock was third. A strong class was that for two vases, in two distinct varieties, three blooms of each, there being seven competitors. Mr. Raynor Bullock again topped the list with some well-built flowers of Master James and Reginald Vallis; second was claimed by Mr. Mark Chatfield, with Reginald Vallis and Montigny, third going to Mr. Alfred Cryer.

Two entries for twelve Japanese blooms, distinct varieties, set up in single vases, with foliage plants or cut foliage as a setting, were a rather poor display after last year's class, which was remarkably fine. Mr. Hugh Andrews was given first prize, his flowers certainly being fine and clean, but the decorative effect of the exhibit would have been improved by the addition of a black velvet or other dark background. Mr. A. W. Young, Edgbaston, was second, using small crotons and maidenhair ferns for decoration. This class should be a popular one.

A novices' class for two vases of incurved, three blooms in each, in two varieties, was provided for growers who have not previously won a first prize. Mr. E. Wright, Bearwood, was the winner, showing shapely flowers of C. H. Curtis and Mrs. J. P. Bryce; second prize went to Mr. Charles Judge, Small Heath, whose flowers were too open. In a class with similar restrictions, for Japanese, Mr. E. Wright again led; Mr. G. Palmer, gardener to P. J. Worsley, Esq., Edgbaston, being second prize winner.

Amateurs who do not employ a gardener were provided for, three entries being staged in the incurved class for three blooms in each of two vases, each vase to contain one distinct variety. The winner was Mr. J. Wakefield, Harborne; Mr. E. Clift, Blackheath, and Mr. E. Darby, Aldridge, following. In the Japanese class the same exhibitors accounted for the prizes in the same order.

There was an open class for a collection of cut single chrysanthemums arranged on a table space 8ft. by 4ft., foliage plants, etc., being allowed. It made a very good class, the winner, Mr. H. Tribe, putting up a fine lot of well-grown flowers in good varieties, the staging being artistic and effective. Mr. W. Newton, The Garden, Knowle Hall, came a good second, his flowers showing careful cultivation, although too severely disbudded for singles. Mr. Raynor Bullock was third, his flowers being staged on the flat staging instead of on tiers.

Table decorations of chrysanthemums filled a large amount of space, and were very much admired. There was naturally a considerable amount of repetition or sameness in a series of over twenty tables, furnished almost entirely with single and small-flowered chrysanthemums, but the exhibits demonstrated admirably the value of the flower for decorative purposes. First honours were secured in this keen competition by Mr. H. Greaves, Wormington Broadway, Worcester; Mr. E. Deakin, Hay Mills, being his runner-up.

MISCELLANEOUS PLANTS.

These are not shown here to anything like the extent of former years. Nevertheless, there were some good exhibits. Twelve cyclamen made a class of three entries. Mr. A. Shambrook, gardener to the Rev. H. Buckston, Sutton Hall, Derby, leading with beautiful plants carrying good flowers over well-developed foliage. Mr. G. Corbett took second prize, also having nice plants, but the flowers were smaller and shorter in stem; third, Mr. G. L. Blackburn. Begonia Gloire de Lorraine, as usual, made a big, brave display, the plants being examples of expert culture. Mr. J. Freeman, gardener to Colonel Walker, Acocks Green, scored easily, his plants standing out conspicuously among the whole table of entries. Mr. A. Cryer and Mr. G. Corbett followed, the last-named showing a darker and richer-coloured type than the rest. For six plants the lead was taken by Mr. A. W. Young.

FRUIT.

It was the general comment that the fruit was better than ever, and it must be remembered that good fruit has many a time been seen at Birmingham Show. There were four splendid entries in the class for a table of fruit (British grown), including grapes, 10ft. by 5ft., and competition was extremely keen. Mr. J. H. Goodacre, gardener to the Earl of Haddington, Elvaston Castle, Derby, stood first, and it was a hard-won victory. There were fourteen bunches of splendidly-grown grapes; dishes of such apples as Emperor Alexander, Gascoigne's Scarlet, King of the Pippins, Washington, and many more; as well as melons, pears, peaches, oranges, etc., the arrangement of all, and especially the use of trails of ampelopsis and selaginella, being in the best of taste. Mr. G. Mullins, gardener to Lady Henry Somerset, Eastnor Castle, Ledbury, came second with a superb lot of fruit, his Charles Ross, Claygate Pearmain, Baumann's, and Annie Elizabeth apples carrying wonderful colour, and his grapes being beautifully finished. Mr. Hugh Andrews, Wynchcombe, secured third prize, showing some grand pears and apples, but he was weak in grapes. Mr. W. E. Hyde, Ledbury, was fourth.

Another class of importance and interest was that for a collection of hardy British-grown fruit, for which a first prize of £5 cash and a silver-gilt medal was offered. The winning exhibit was a remarkable table of superb apples put up by Mr. C. W. Powell, Warham, Hereford. King Edward, Cox's and King of Pippins, Lady Henniker, Lord Derby, Peasgood's, and many other of the favourite dessert and culinary apples were the talk of the show, and there were also nice examples of pears, medlars, nuts, etc.

Grapes were very good, Mr. Goodacre staging wonderfully finished Muscats and Appley Towers, winning in both black and white classes. Mr. Ganderton, gardener to A. G. Buller, Esq., King's Heath, was also a winner of first for white grapes grown in the Birmingham district, Mr. Smallman, gardener to H. S. Batson, Esq., Handsworth Wood, winning for black grapes in the local class. In both the eight-dish and four-dish classes for pears Mr. G. Mullins scored highest honours with splendid fruit, and again in the six dishes of dessert and six dishes of culinary apples.

VEGETABLES.

These made a capital display, in spite of all that has been said and written of our much-discussed and abused summer. The great seed firms again provided classes in which competition was very keen. There were half-a-dozen entries for a collection of eight kinds, prizes provided by Messrs. Webb and Sons, and first position was taken by Mr. Fred Bennett, Overton; Mr. Hudson, of Leicester, being second, and Mr. A. T. Rainbow, Northfield, third.

Messrs. Sutton's class brought eight entries, the champion exhibitor, Mr. Edwin Beckett, adding still further to his laurels by scoring an undoubted win. His follower was Mr. Fred Barrett, Overton; Mr. Hudson coming third, and Mr. Hugh Andrews fourth. Messrs. Sydenham, Lim., drew five entries in their open collection, Mr. Tom Jones, Ruabon, leading, second prize going to Mr. W. Foulkes, Ampthill; Mr. James White, Bampton, third; Mr. E. Haytree, Solihull, fourth. Capital stuff was shown in the single-dish classes, which were very numerous.

NON-COMPETITIVE.

The season may be bad, and competition in the amateurs' section may fall off under adverse circumstances, but the trade always appear to surmount all difficulties, and make a brave show. It certainly was so on this occasion, when the non-competitive exhibits were more numerous, and also more varied in character than last year. It has always been characteristic of Birmingham Show that, in addition to chrysanthemums, fruit, and vegetables, a goodly display of other subjects come before the public, and undoubtedly the inclusion of fine groups of conifers, hollies, and other ornamental trees and shrubs, and also exhibits of ferns, pelargoniums, carnations, etc., add immensely to the attractiveness and interest of a winter show. Mr. W. J. Godfrey, Exmouth, a regular exhibitor at Birmingham, confined his attention this time to a fine display of single and decorative chrysanthemums and a bright bank of zonal pelargoniums. Among the single chrysanthemums Primrose Girl, a clean yellow, with broad, straight florets; Mrs. F. G. Hunter, deep golden, highly spoken of by many growers present; and Barbara, a long-petalled bronze, were attractive and distinct.

Messrs. Young and Co., Hatherley, Cheltenham, showed perpetual carnations in good form. Cheltonia, a particularly bright red; the crimson Duchess of Devonshire; and Queen, a pleasing yellow-ground fancy, were among other good and popular sorts. One of the best exhibits of large Japanese chrysanthemums was that staged by Mr. H. Woolman, Shirley, Birmingham. His stands of Maritana, Hon. Mrs. Lopes, Sir Albert Rollit, D. B. Crane, and others contained well-developed flowers, set up with decoratives as a groundwork. Mr. H. N. Ellison, West Bromwich, showed greenhouse ferns in many choice varieties. He also had a fine stand of the Adnet strain of hybrid gerberas.

Chrysanthemums on regulation show boards, in tall pyramidal stands, and in single vases, were shown in great variety by Messrs. W. Wells and Co., Lim., Merstham. The beauty of the flowers was shown to great advantage by the use of cyrtomiums, Asparagus Sprengeri, and bronze oak foliage. Messrs. Wells also showed some of the finest singles we have seen this season, and a further feature were some very fine perpetual carnations. It was a grand exhibit. Mr. A. W. Thorpe, Lichfield, showed early-flowering chrysanthemums cut from the open. Such varieties as Vesuve, Vesta—a new white of merit—Golden Glow, and others were particularly fine for so late in the season.

Standard hollies of beautiful symmetry were an outstanding feature of a fine exhibit of trees and shrubs put up by Messrs. John Waterer and Sons, Lim., Bagshot. Tall pyramidal specimens of Cupressus Lawsoniana aurea, and Taxus fastigiata Standishi, and such good things as Abies lasiocarpa, Cedrus atlantica glauca, etc., all helped to make a very interesting exhibit. A big group of conifers came from Messrs. Hewitt and Co., Solihull. Abies pungens glauca, golden retinosporas, shapely cupressus, etc., were set up with a few good hollies and other useful subjects. Messrs. Bakers, Wolverhampton, also had a good exhibit of shrubs, some highly-coloured Cryptomeria elegans, and beautifully berried cotoneasters adding brightness to the display. Small shrubs, conifers, and veronicas were staged by Messrs. T. B. Grove and Son, Sutton Coldfield. Veronica selaginoides, V. Hectori, and V. epacridea were well represented.

King's Acre Nurseries, Lim., Hereford, put up a very extensive collection of beautifully-finished apples and pears. Admiration, a new apple, was well shown, and was favourably commented upon. British Queen, another of the firm's new apples, was also good, but the whole display was a credit to the firm. A big table of apples, packed in boxes as for market, came from Messrs. Pewtress Bros., Tillington, Hereford. The fruits were of popular varieties, excellent quality, and well graded. Messrs. H. Cannell and Sons, Eynsford, Kent, were large exhibitors of fruit; while Messrs. Geo. Massey and Sons, Spalding, put up gourds in remarkable variety, together with other well-grown vegetables. Other fine exhibits of fruit were a collection staged by Mr. J. Taylor, gardener to Frank Bibby, Esq., Hardwicke Grange, Shrewsbury; a fine lot of apples from Mr. J. H. White, Worcester; and a display by the Hereford Fruit Growers' Association.

A large table was furnished in quite an ornate style with vegetables by Messrs. Clibrans, Altrincham. Celery, leeks, and seakale beet were fixed perpendicularly, while golden tomatoes, brilliant capsicums, many-coloured gourds, and black potatoes, arranged in dishes and baskets, produced colour effects rarely seen in vegetable exhibits. Messrs. E. Webb and Sons, Wordsley, had their temple-like device, which they decorated with single chrysanthemums and foliage. The table-base was filled with well-grown vegetables, the central mound being furnished with celosias, begonias, and ferns. Vegetables were also largely shown by Messrs. Thomson and Co., Birmingham, and Messrs. Toogood and Sons, Southampton. A collection of capsicums in pots, gourds in variety, and miscellaneous vegetables was tastefully arranged by Messrs. W. H. Simpson and Sons, Birmingham.

Mr. E. V. Low, Haywards Heath, had a nice lot of orchids, chiefly comprised of hybrid cattleyas.

SUNDRIES.

Messrs. Sankey and Sons, Lim., Bulwell, Notts, made quite an attractive show of garden pottery, the designs being ornamental, but still suitable to the proper treatment of plants.

Four Oaks spraying machines and undentable syringes were exhibited by the well-known manufacturers, of Four Oaks, Sutton Coldfield.

Garden requisites of every description were staged by Mr. G. H. Richards, Borough High Street, London. The XL All specialities were supplemented by samples of peat, osmunda fibre, tools, and chemicals of varied uses.

MEDAL AWARDS.

Large Gold.—Messrs. Webb and Sons, Stourbridge; Messrs. John Waterer and Sons, Bagshot; Messrs. Clibrans, Altrincham; Messrs. Pewtress Bros., Hereford; King's Acre Nurseries, Lim, Hereford; Messrs. Geo. Massey and Son; Messrs. Toogood and Sons, Southampton; Messrs. Rd. Sankey and Son, Lim., Nottingham.

Small Gold.—Mr. W. H. Simpson, Birmingham; Messrs. Thomson and Co., Birmingham; Messrs. Hewitt and Co., Birmingham; Messrs. Godfrey and Son, Exmouth; Messrs. Young and Co., Cheltenham; Mr. H. Woolmans, Shirley; Messrs. Wells and Co., Merstham, Surrey; Messrs. H. Cannell and Sons, Swanley; and Frank Bibby, Esq.

Silver-gilt Medals.—Mr. E. V. Low

Silver Medals.—Mr. H. N. Ellison, West Bromwich; Miss Thompson; Messrs. J. H. White and Son, Worcester; Messrs. Bakers, Wolverhampton; and Mr. Thorpe, Lichfield.

Bronze Medals.—Messrs. Thomas B. Grove and Son, Sutton Coldfield; Councillor E. Wilson, Edgbaston; and Mrs. Bissell.

Aberdeen Horticultural Society.

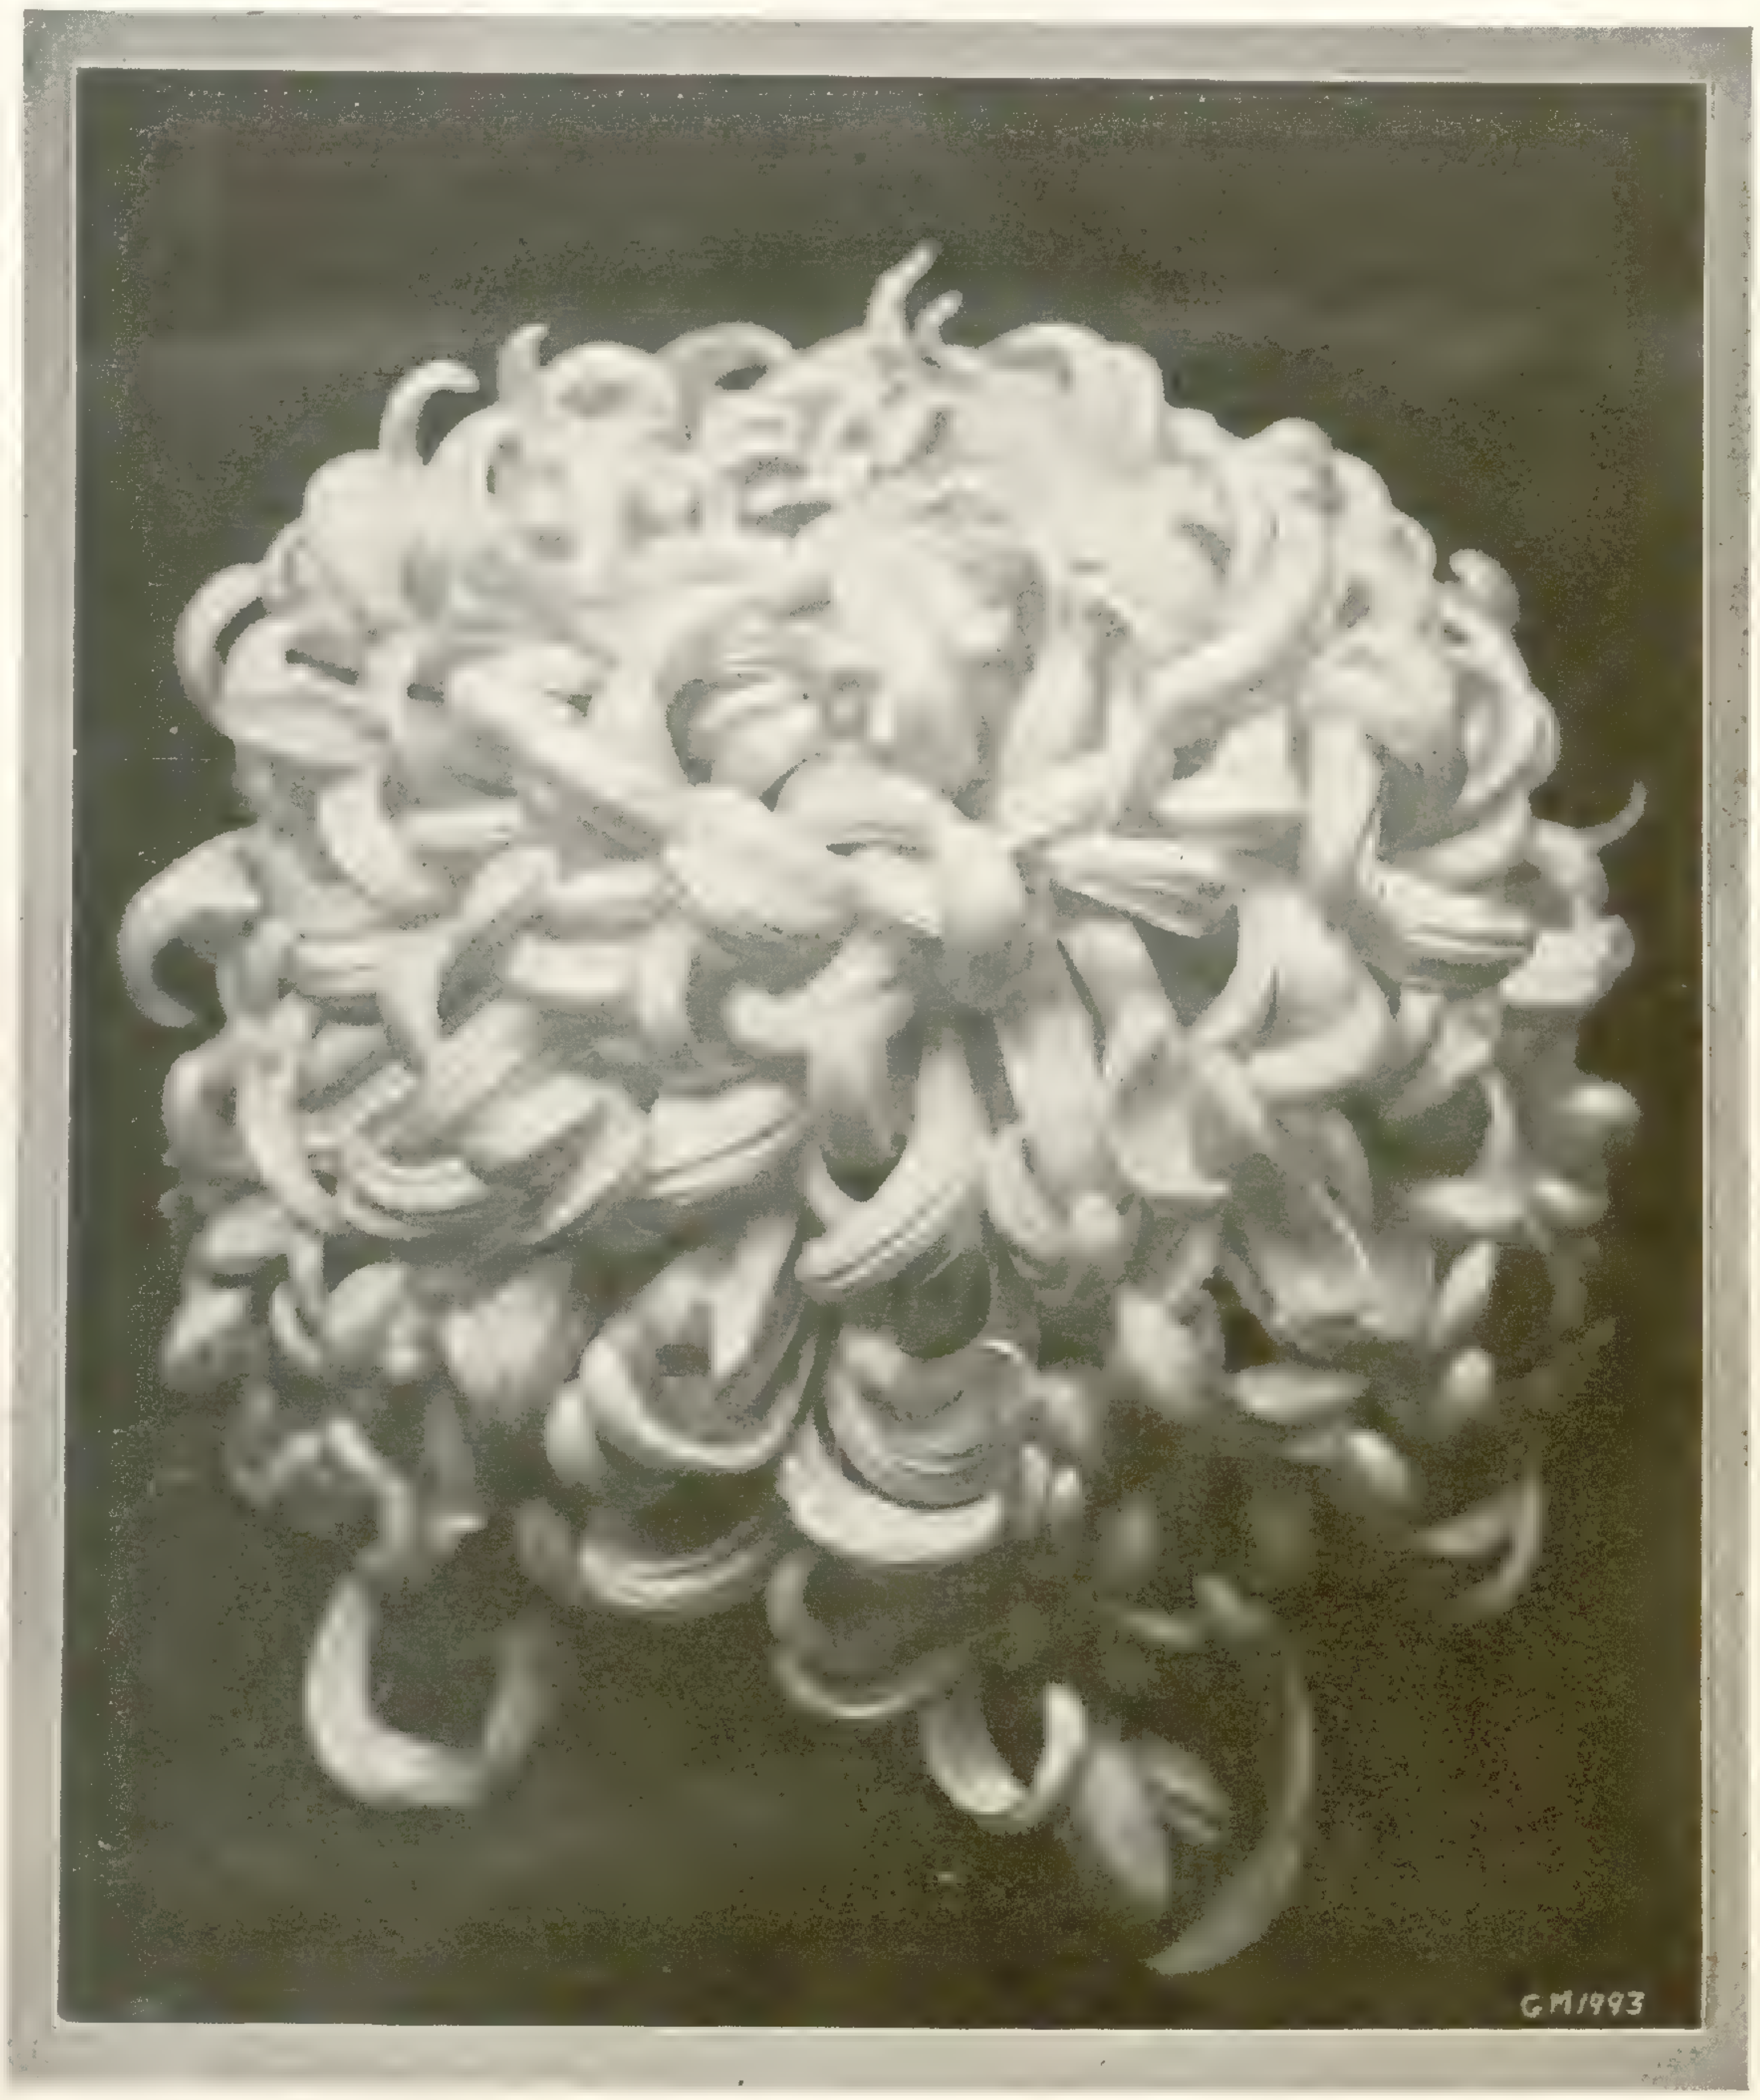
Despite the exceedingly inclement weather prevailing, a very large number of members attended the annual general meeting of this society in the Music Hall Buildings, Aberdeen, on Saturday evening, 4th inst. The chair was occupied by Ex-Baillie Milne, vice-chairman of the society.

The annual report showed that the society's exhibition, held in the Duthie Park, Aberdeen, in August last, was, from a horticultural point of view, both in number and in quality of exhibits, one of the most successful ever held under the auspices of the society. The financial results were also exceedingly satisfactory. The income for the year amounted to £497 15s. 7d., and the expenditure was £471 15s. 8d., leaving a surplus of £25 19s. 11d., which, with the credit balance of £1 7s. 11d. at the beginning of the financial year, left a balance of £27 7s. 10d. to be carried forward to next year. The Chairman described the report as very satisfactory, and said the society ought to be very grateful to their secretary and treasurer, Mr. J. B. Rennett, for his valuable assistance during the exhibition. Mr. George Alexander seconded the motion, and it was carried unanimously.

The hon. president, vice-president, and directors were re-elected. Colonel W. S. Gill was again cordially re-elected chairman of acting directors, and Ex-Baillie Milne as vice-chairman. Messrs. W. Reid and W. Wyllie were again appointed auditors, and Mr. J. B. Rennett was unanimously re-elected to the post he so worthily fills of secretary and treasurer.

The following leading gardeners, nurserymen, florists, etc., were elected as acting directors: Messrs. W. Anderson, W. Adam, W. Cumming, A. Douglas, A. Brebner, A. M. Cocker, J. Macdonald, A. Giles, W. Slora, J. Coutts, Parish Councillor Simpson, W. Walker, A. Duncan, A. Burns, jun., J. George, J. Marr, J. Duncan, W. Lockhart, G. Macdonald, and D. Ritchie.

The usual votes of thanks concluded a very pleasant and harmonious meeting.



CHRYSANTHEMUM MRS. GILBERT DRABBLE.

A fine white Japanese variety exhibited at Birmingham Chrysanthemum Show by Messrs. W. Wells and Co., Merstham.

Bristol Gardeners' Association.

The usual fortnightly meeting was held at St. John's Parish Rooms, Mr. A. Perry in the chair. A thoroughly interesting paper on "The Rose; with Cultural Hints," was given by Mr. J. F. Merchant, of Bath. The lecturer chiefly confined his remarks to the history and origin of the different races, and mentioned that South America and Australia are the only countries where the rose has no representative. He said a greasy loam was the most suitable soil, and if not of this nature manure from the cow stall should be added, as well as bone-meal. He advised pruning ramblers in the autumn and other varieties in March and April, and if of moderate growth to cut back to three or four plump eyes, but if vigorous to leave eighteen inches.

For a dish of pears Mr. Scott was first; Mr. Spry second. Two new members were elected.—H. W.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

RUST ON CARNATIONS.—J. W. L., Taunton: The leaves and shoots sent give ample evidence of a very bad attack of the carnation rust, known as Heterosporium echinulatum. Try a slightly stronger solution of potassium sulphide, pick off and burn diseased leaves, so as to reduce the possibility of infection to a minimum. Apart from the spraying keep the foliage and atmosphere as free from moisture as possible by using fire heat, together with ample ventilation. Newly-purchased plants should be quite isolated from the general collection for some time after receipt, so that should disease develop it may be promptly dealt with.

EXAMINATION IN HORTICULTURE.—H. W., Shotley: At the time of writing the date of the next examination in horticulture to be held by the Royal Horticultural Society has not been made known. Write to the secretary of the society, Vincent Square, Westminster, London, S.W.

ZEPHYRANTHES CANDIDA.—D. B. S., Colbrook: This charming little autumn-flowering bulbous plant deserves to be much more generally planted than it is, but it is of little value if only a few isolated specimens are grown. Colonies in the rock garden, good breadths in the foreground of warm borders, or long marginal bands, should be planted, as it is in the mass that Zephryanthes candida makes such a beautiful display. Deep, well-drained and fairly rich soil is essential to success, and if the position is a warm one, such as a border running along the sunny side of plant or fruit houses, or close to a warm south wall, no difficulty will be found in securing a fine display of bloom in September. The best time to plant the zephyranthes is in July.

NEED FOR LIME IN SOIL.—A. R., Notts: If the sample of soil sent fairly represents the whole of the area to be dealt with, then the addition of lime will prove most beneficial. The lime sent is not of the best, but it will serve very well if broken down finely before distribution. Use it at the rate of two tons per acre, or, say, half a pound or so per square yard. Harrow, hoe, or lightly fork the lime into the soil as soon as it has been spread.

DRESSING FOR LAWN.—C. R., Hampstead: A good dressing for such a lawn would consist of good garden soil or old potting soil, mixed with old mushroom-bed manure and wood ashes, using two parts of the former to one each of the latter; pass the whole through a quarter-inch mesh sieve while fairly dry, and then to each cubic yard of this material add half a hundredweight of bone-meal. Thoroughly mix all together, and while it is still dry spread it as evenly as possible at the rate of a garden barrow load to every eight square yards of lawn surface. An ounce of sulphate of ammonia per square yard in April next will also prove very beneficial. The top-dressing recommended above should be applied during the present month, spread evenly with the back of a rake, and then lightly swept with a birch broom to work the material well into the grass. An interesting and useful book on this subject is "Lawns and Greens," post free 1s. 2d., from the GARDENERS' MAGAZINE Office, 148, 149, Aldersgate Street, E.C.

DISEASED LARCH BRANCH.—F. E. M., Oxford: Wherever larch is planted on low and damp ground, its usually vigorous constitution suffers, and it becomes liable to disease. The branch shows that the Larch Canker fungus (Dasyscypha calycina) is at work. Cut the branch back well behind the affected part, and immediately dress the wound with a strong solution of sulphate of iron, following this by painting the cut surfaee with tar. Carefully search for further evidences of the disease, and if any are found on a main stem, cut out the infected portion, and treat the cut surface at once with the sulphate of iron and tar dressings. All diseased portions should be burnt directly they are removed from the tree.

CLIMBING HYDRANGEA.—E. Y., Bideford: There are two plants, of somewhat similar appearance, known in gardens under the title of Climbing Hydrangea. One is Hydrangea petiolaris and the other Schizophragma hydrangeoides. The plant commonly found in gardens as Schizophragma hydrangeoides is identical with Hydrangea petiolaris, but S. hydrangeoides, Sib. and Zucc., is a distinct plant from the one which so often bears that name, and different from the H. petiolaris figured in the "Botanical Magazine," t. 6,788. Hydrangea petiolaris is a tall climbing Japanese shrub which needs the shelter of a wall in many parts of the country; it produces flattened corymbs of white flowers in June.

NAMES OF PLANTS

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

T. W., Berkhampstead.—Iris fœtidissima.

C. R., Amesbury.—1, Cratægus pyracantha Lelandi; 2, Veronica Andersoni.

A. R. B., Lincoln.—1, Pteris semi-pinnata; 2, Nephrodium molle; 3, Adiantum Birkenheadi.

M. M. C., Reigate.—1, Juniperus chinensis; 2, Schinus molle; 3, Hippophæ rhamnoides; 4, Skimmia japonica.

B. P., Canterbury. 1, Ruscus racemosus; 2, Caryopteris mastacanthus; 3, Eupatorium Wienmannianum; 4, Nerine Fothergilli major.

E. G. G., Hemsworth.—1, One of the newer hybrids from Fuchsia triphylla; 2, not recognised, send when in flower; 3, Nerium Oleander; 4, Hibiscus rosa-sinensis semiplenus.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

B. W., Torquay.—1, Golden Noble; 2, London Pippin; 3, Alfriston.

F. C., Chelmsford.—1, Durondeau; 2, Warner's King; Mère de Ménage.

H. M. L., Altrincham.—1, Court Pendu Plat; 2, Fearn's Pippin; 3, Newton Wonder.

R. R. W., Hull.—1, badly damaged, not recognised; 2, King of the Pippins; 3, Bramley's Seedling; 4, Cox's Pomona.

L. D. J., Ross.—1, Alfriston; 2, not recognised; 3, Annie Elizabeth; 4, New Hawthornden; 5, Baumann's Red Reinette; 6, Minchull Crab.

E. W., Kidderminster.—1, Beauty of Kent; 2, Beurre Clairgeau; 3, Beurre Diel; 4, Peasgood's Nonsuch; 5, Lord Derby; 6, Lady Henniker.

APPLE KING EDWARD VII.

It is very seldom we find "E. M.'s" writings (see page 822), so far from the facts, as they undoubtedly are, when he states that King Edward is similar in "appearance, quality, flavour, growth, and keeping qualities, to Bramley's Seedling." Our experience is the very opposite, and this dates back from long before King Edward received an A.M. from the Royal Horticultural Society. King Edward is reputed to have been raised from a cross between Blenheim Pippin and Golden Noble; the latter parent it closely resembles in appearance, which cannot be said of Bramley's. In quality it is A1, does not go "down" in cooking, and is the densest and heaviest apple known. In flavour, it is crisp and juicy; quite a useful dessert variety after March. In growth it is peculiarly short-jointed and sturdy, rather small wood, with very small leaves, much like Waltham Abbey Seedling. Its keeping qualities leave nothing to be desired, for the raiser invariably boasted that he always had a tart of King Edward apple in July. It will thus be seen these two excellent apples are very dissimilar, hence my contradiction of "E. M.'s" statements. There is room for both varieties in any medium-sized collection, they are worthy of extension, in fact; there are large quantities already planted in Worcestershire orchards, cropping well, and in every way satisfactory. It may be mentioned that the green shining skin of King Edward becomes a beautiful rich golden colour in the spring. W. CRUMP.

Madresfield.

The Lyon Rose.—Before another rose season it is to be hoped that an understanding will be come to regarding the colour of this beautiful rose, for it seems absolutely out of place to award it a prize as the best white or yellow rose, as has been done during the past season. I am surprised that exhibitors have not raised a voice of protest in the matter, for it seems ridiculous to call it a yellow flower, beautiful though it be.—W.

Lasiandra macrantha.—There is a widespread idea that this Brazilian shrub, which botanists now tell us should be known as Tibouchina semi-decandra, requires more heat for its successful culture than it really does. As a matter of fact, it readily conforms to greenhouse treatment, not, it is true, in a structure from which frost is barely excluded, but where a buoyant atmosphere and a temperature between 50 and 60 deg. is maintained during the winter; in fact, just such a structure as is essential to maintain plants in flower at that season. During summer this lasiandra needs exposure to air and sunshine, whether it be grown in bush form or trained up the end of the greenhouse. This exposure is necessary to the production of blossoms, and under such treatment the large salver-shaped tyrian blue flowers are borne in great profusion throughout the autumn months. It was a favourite subject for growing into specimen plants when these were more popular than they are now.—W.

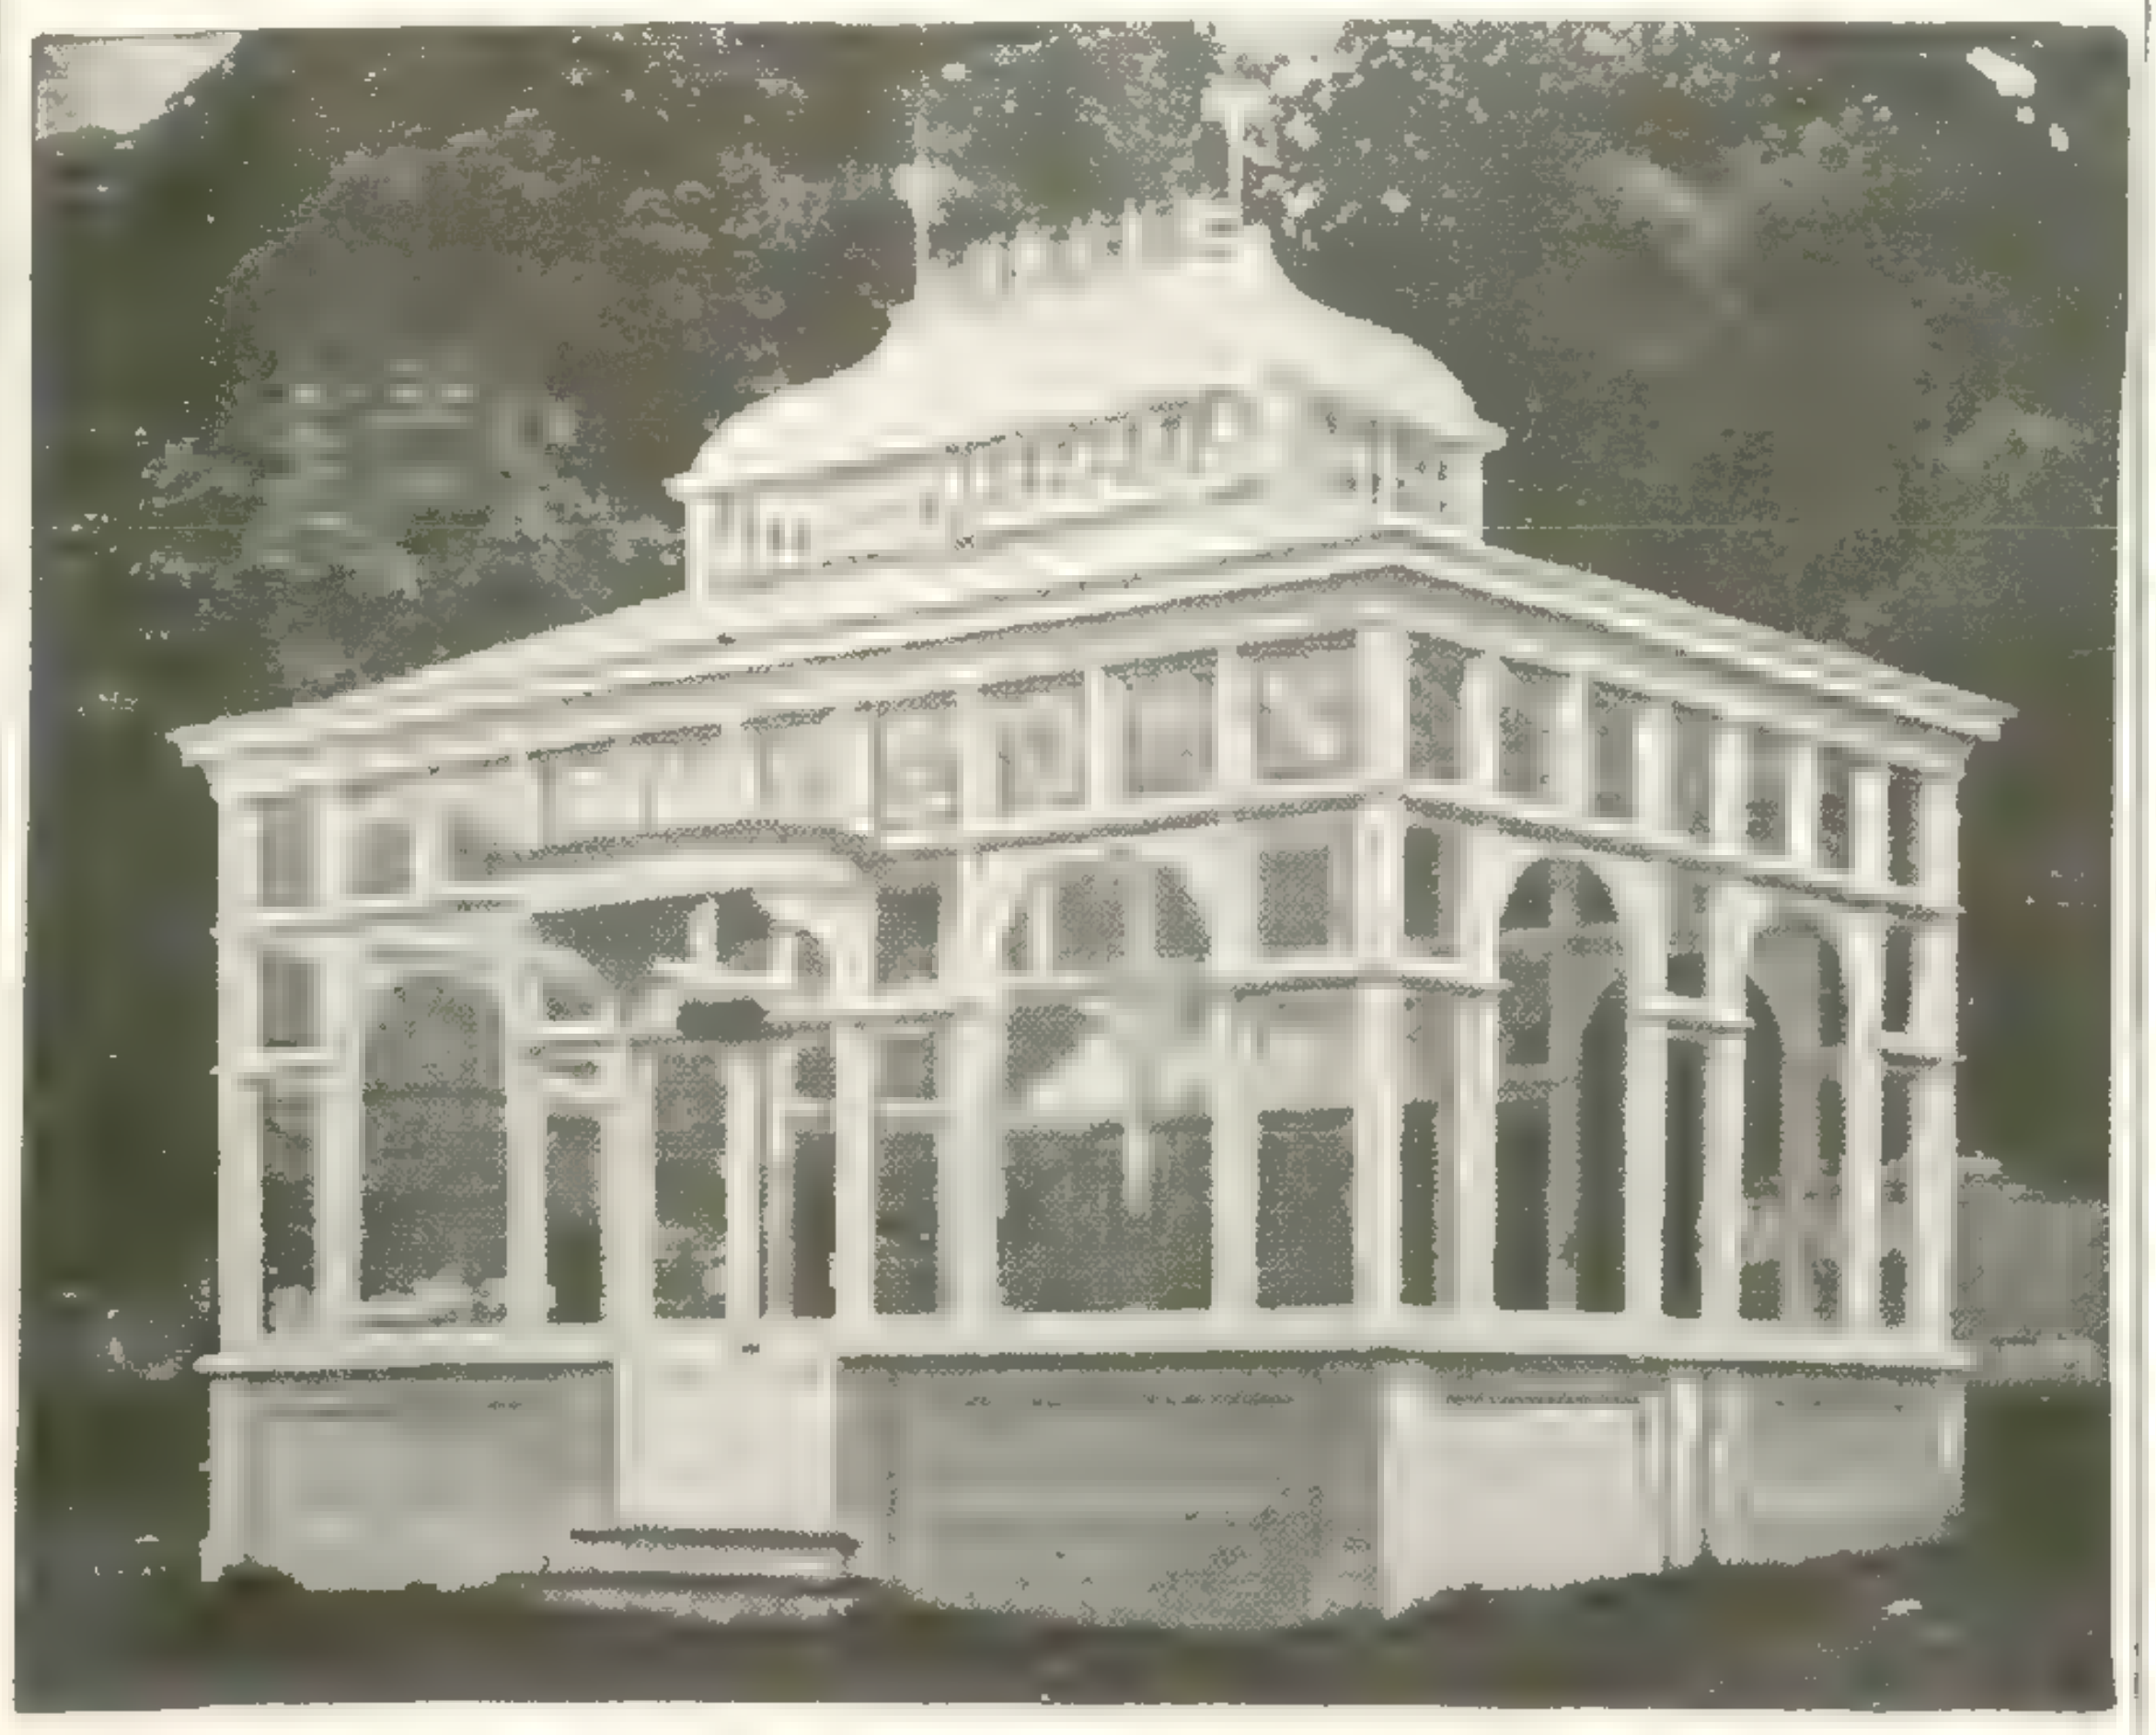
The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price **10/6.** Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).

BOULTON & PAUL, LTD., HORTICULTURAL BUILDERS, Norwich.

ATTRACTIVE, PRACTICAL GLASSHOUSES.

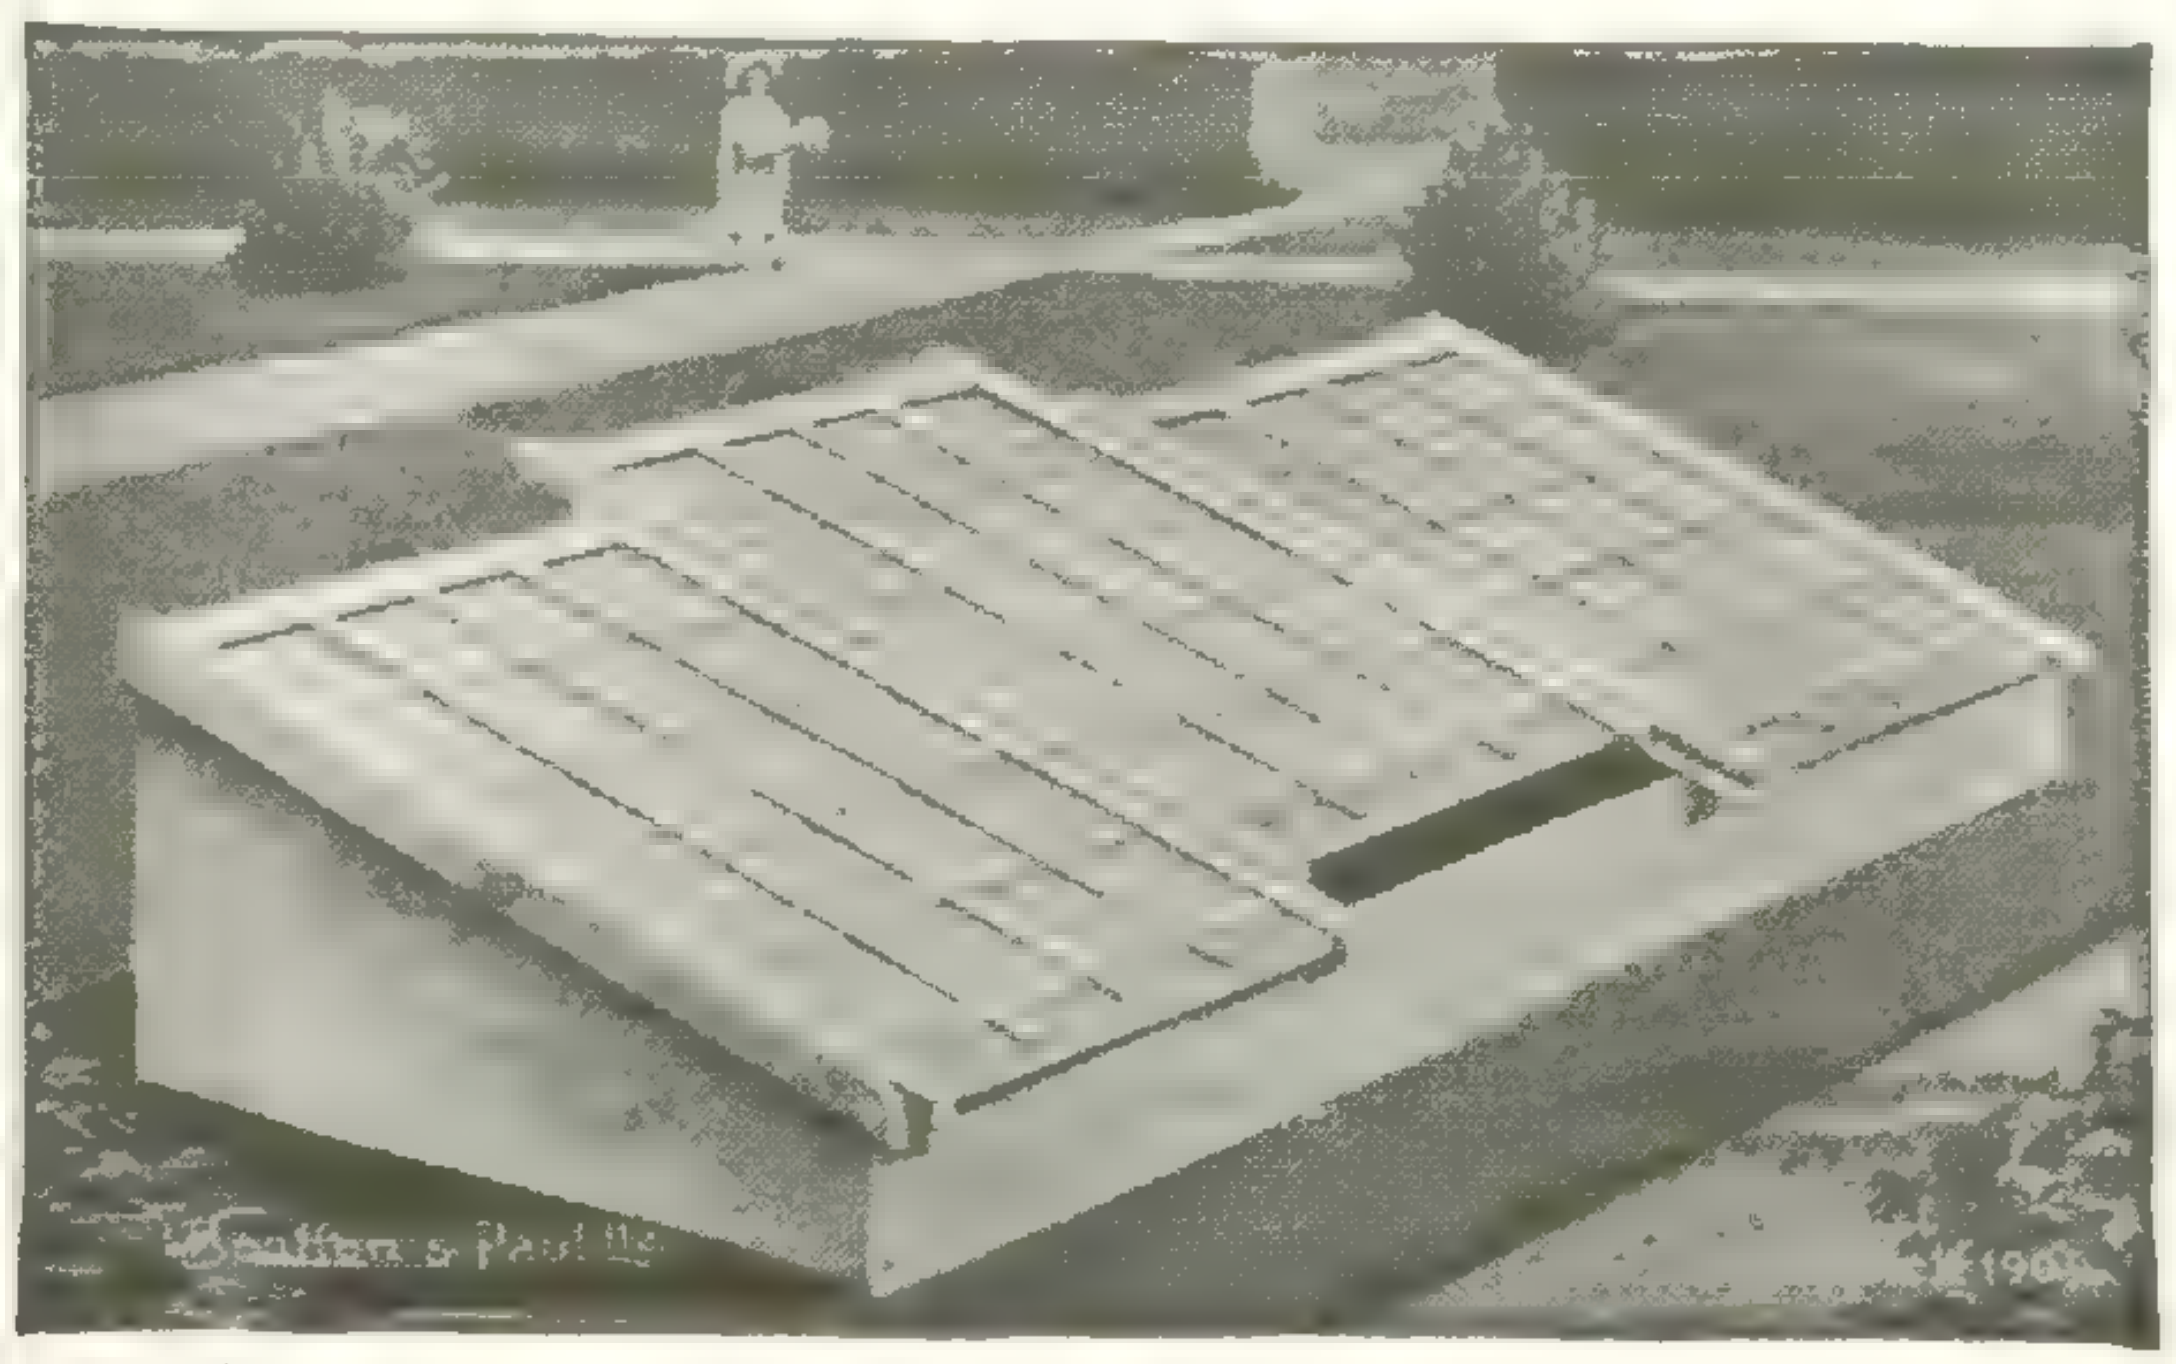


Ladies and Gentlemen waited upon by appointment.

CARRIAGE PAID on orders of 40/- value to most Goods Stations in England.

HEATING APPARATUS installed in COUNTRY HOUSES, HORTICULTURAL & PUBLIC BUILDINGS.

No. 75.—MELON and CUCUMBER FRAME.



4ft. by 6ft. ... £2 0 0 | 8ft. by 6ft. ... 3 0 0
Painted three coats. Glazed with 21oz. glass.

No. 77.—VIOLET FRAME, 6ft. by 4ft. Similar to No. 75, with Two Lights... 35/-

SEND FOR ILLUSTRATED CATALOGUES.

Every part of these Houses is thoroughly well made, painted three coats, GLAZED AT OUR WORKS WITH 21oz. GLASS and CARRIAGE PAID.

MODERN GLASSHOUSES

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

Printed and Published by W. H. & L. Collingridge, City Press, 148 & 149, Aldersgate St., London, E.C., and sold by all Newsagents, and at all Railway Bookstalls.

VOL. LIV.—No. 3,029. SATURDAY, NOVEMBER 18, 1911.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

British Woodlands.

In view of the increasing interest that is being taken in the woodlands of the United Kingdom as a source of profit and a means of supplying in greatly increased quantities well-grown timber, we have devoted considerable space in this issue to arboricultural matters of importance. The limitation of space imposed by the necessity for dealing at the present time with ornamental trees and shrubs for the garden has prevented our entering so fully into questions relating to forestry as we could have wished. But we have been fortunate in securing the aid of some of the leading foresters in the country, and, as they happily possess an acquaintance with the scientific aspects of forestry, as well as a full knowledge of practical work, their contributions possess much value, and deserve something more than a superficial glance. They really cover a wide range, and to those who are anxious to extend their knowledge of woodlands, and all who are engaged in practical horticulture should be, they can hardly fail to be both interesting and instructive, and therefore deserving of careful perusal. To be in a position to fully appreciate the necessity for giving increased attention to forest and woodland areas in the United Kingdom, it is necessary to remember that for a long series of years arboriculture was at an extremely low ebb, and that but little attention was given to woodlands as a source of profit. It was felt by many owners of large estates that, with the displacement of ships of wood by vessels of iron, and some other changes in industrial conditions, the need for oak and other hardwood timber had gone. The idea was also entertained that, with the great forests of Northern Europe to draw upon, the growth, except on a small scale, of such timbers as larch and spruce was unnecessary within the British Isles. These mistakes were great, but still greater was the belief so generally held that woodland areas could be properly managed by those who had no special knowledge of the cultural requirements of trees or the commercial value of their timber. The importance of placing the management of the gardens on an estate under the management of a gardener who had undergone a thorough training was fully recognised. In like manner it was regarded as essential that the charge of the home farm should be entrusted to a fully qualified bailiff; but in the case of the woods many owners acted upon the assumption that if the woods were not able to take care of themselves, almost anyone was able to take charge of them. As the result of these mistaken views, which were held over a long period, the woods and forests of this country passed into a neglected and very unsatisfactory condition. They became consequently unprofitable, and it has not been an uncommon occurrence to hear speakers at meetings at which reforms in the management of woodlands were being advocated contend that such reforms were impracticable because of the impossibility of obtaining a profit from the growth of timber, and quoting from the balance-sheet of their estates in support of their contention. Forestry may not be of great economic importance on estates of moderate area where the whole of the land is suitable for pastures, or the cultivation of crops that are usually grown on properly managed farms; but on all estates of any considerable size there should be woods and plantations, and these should be so dealt with as to contribute to the amenities of the respective districts, and to the financial returns from the estates. On the other hand, in those parts of the kingdom, where large tracts of land are quite unsuitable for pasturage and the production of cereal and root crops, the development of woods and forests becomes a matter of serious import, both to their owners and to a considerable proportion of those who are engaged in rural industries. In the interest of these two important classes of the community it is highly gratifying to know that this fact is being recognised, and that well-devised efforts are being made to bring about an amelioration of the unsatisfactory state of things that have so long obtained. It has on more than one occasion been said at meetings at which we have been present that the area of the United Kingdom is far too small to admit of any considerable portion being devoted to forests, but such contention indicates a very imperfect knowledge of the subject. What should be done is not devoting rich meadow and arable land to woods and forests, but the utilisation of such land as is not suitable for ordinary crops in the growth of timber, and this view is now generally accepted by those who have given full consideration to the matter. Much has already been accomplished in bringing about an improved state of things, but not a little has yet to be done in various directions before the state of forestry can be regarded as thoroughly satisfactory. As will be readily understood, it is not possible to bring about changes in woodlands at a very rapid rate, but they are being made, and we may anticipate that with a steady increase in the number of skilled foresters, the rate will be considerably accelerated. In an early issue the question of forestry as a profession will be dealt

MR. H. PRIME.

with, and in the meantime we would suggest that, as the management of woods and plantations is frequently entrusted to the gardener, all who are engaged in garden management should take advantage of such opportunities as may be within their reach for becoming acquainted with trees that are valuable for their timber, as well as those grown simply for ornament.

Mr. H. Prime, who has for some years past been in charge of the extensive gardens of Hatfield House, the historic seat of the Marquess of Salisbury, has, by means of the excellent work he has done, fully maintained their traditions, and obtained for himself a prominent place among the many good gardeners that carry on their avocations within the County of Hertford, which is remarkable for the number of its horticultural establishments. Mr. Prime has certainly made good use of his opportunities since he commenced his gardening career at Stoneleigh Abbey, under Mr. Beddard, for the gardens at Hatfield House testify in no uncertain manner to his thorough acquaintance with all that tends to success in the management of the several departments. During the period that intervened between Mr. Prime leaving Stoneleigh Abbey and being appointed to the high position he now occupies, he filled positions of importance in several great gardens. He was the foreman two years in the gardens of Hatfield House, under the late Mr. George Norman, V.M.H., and, on the death of his chief, he was appointed his successor. Mr. Prime has afforded evidence of his cultural skill by his contributions to the meetings of the Royal Horticultural Society, especially noteworthy being the exceptionally fine groups of Begonia Gloire de Sceaux and Euphorbia fulgens, of which illustrations were given in these pages. Mr. Prime also exhibited lachenalias at Westminster that possessed much value as an object-lesson in the cultivation of these flowers for decorative purposes.

A Ship's Model in Flowers.—On the departure of the King and Queen for India, their Majesties gave a farewell luncheon on board the "Medina." The principal table was decorated with a model of the ship, in white heather and pink carnations, made by Messrs. Garrard.

Fruit Show and Congress at Newcastle.—On November 15 and 16 the Newcastle Horticultural Society held a splendid chrysanthemum show in the Town Hall and Corn Exchange, and, in conjunction with this exhibition the North of England Horticultural Society held a fruit show and conference, the latter dealing chiefly with fruit culture in the Northern Counties. It was unfortunate that the conference was held in the Mining Institute, some little distance from the Town Hall. Mr. W. Alexander, of Hexham, was the leading prizewinner in the fruit section, and Mr. Musk, of Wiseton Gardens, Notts, the chief winner with flowers. The exhibition was opened by Lady Grey, the opening ceremony being well attended, and presided over by the Lord Mayor of Newcastle. At the afternoon conference, Captain Cuthbert presided over an attendance of about three dozen persons. Mr. Chisholm and Mr. W. B. Little discussed fruit cultivation, with special reference to dessert apples for the north. Later, a further session was held under the presidency of Dr. W. H. Hadow, Principal of Armstrong College, when "Horticultural Education" was the matter dealt with, Mr. F. J. Chittenden, of Wisley, and Mr. P. P. Walker, of Armstrong College, being the lecturers. This proved a most interesting subject, and one that was ably discussed by Mr. G. P. Berry, Horticultural Instructor to the Edinburgh Agricultural College, and Mr. Hosking, Horticultural Instructor to the Glasgow Agricultural College. Unfortunately, the attendance was again very small. We were glad to learn that in the evening of the first day the Treasurer was able to report a good advance in the takings at the gate, as compared with the first day last year.

Change of Colour in Primula farinosa.—At the meeting of the Scientific Committee of the Royal Horticultural Society on the 7th inst., Mr. George Gordon, V.M.H., mentioned that, when investigating early in June last, the flowers growing on the northern slopes of the Eiger, in the Grindelwald Valley, he found a plant of Primula farinosa, with flowers having a distinct white centre. The plant was growing at a height of about 5,000 feet, and had several crowns, and was bearing five or six trusses of bloom; the flowers were rather above the normal in size, and the centre was pure white and as sharply defined as the paste of a show auricula. The plant was lifted, and carefully put in a small wicker receptacle, and did not show any signs of having suffered from the change. It was given a rather shady position on the balcony of the hotel, and carefully tended, but in the flowers that first expanded after the plant had been lifted the margin of the white centre was less sharply defined, and in the subsequent blooms the colour gradually spread over the centre, and the flowers assumed their normal colour. Flowers that have been developed at Kew have been wholly of the normal colour.

Royal International Horticultural Exhibition.—On Tuesday next, the 21st inst., Mr. Edward White will lecture at the general meeting of the Royal Horticultural Society on the Royal International Horticultural Exhibition, 1912, of which he is the hon. director. The lecture should be of much interest, and the discussion at its close will afford an excellent opportunity for those who are dissatisfied with the revised scale of charges for admission—and they are many—to express their views with regard thereto.

Messrs. Kelway and Son's Successes.—As evidence of the enterprise and skill of Messrs. Kelway and Son, of Langport, who have done such splendid work in the improvement of the various classes of hardy flowers, and in bringing them into prominence, it may be mentioned that the firm has achieved a high degree of success at the exhibitions held this year. The awards made to them for their specialities in flowers, etc., included five gold medals, these being given at the White City Coronation Exhibition, Southampton, Taunton, Cardiff, and Regent's Park (Royal Botanic Society); and four silver-gilt medals and eight silver medals, at the Royal Horticultural Society's shows.

National Vegetable Society.—Owing to the poor attendance of visitors at the two shows held by the above society in London, during 1910 and 1911 respectively, the committee have arranged to hold their exhibition next year in the Clarendon Hall, Watford, Hertfordshire, on Wednesday, October 2. By doing so they hope to bring the work of the society before a more rural population. Watford is noted as a large vegetable-growing centre, and considerable interest is taken in all phases of horticulture by the residents. It is situated on the London and North-Western main line, and is easily reached from most parts of the country. The Clarendon Hall is situated in the centre of the town, and offers every facility for the holding of a large and interesting exhibition. The committee hope that all who are interested in the cultivation of vegetables will join the society and assist them in their good work. The hon. secretary, Mr. E. G. Quick, will be pleased to receive offers of prizes to be competed for at the above exhibition, and also to furnish particulars concerning the work of the society. His address is Kelmscott, Harrow View, Wealdstone, Harrow. The annual general meeting of the members of the society will be held at the Horticultural Hall, Westminster, on Tuesday, November 21, at 2.30 p.m.

Packing Fruits and Vegetables for Market.—The half-yearly conference of the National Federated Association of Fruiterers and Florists was held at Sheffield on Tuesday, and, in the course of the proceedings, the president, Mr. W. E. Boyes, of Leicester, referred to the efforts that the federation is making to induce the Board of Education and the Board of Agriculture to take steps to bring about an improvement in the methods of packing fruits and vegetables for market. Mr. Boyes stated that he had written to the Board of Education asking for the appointment of expert lecturers and practical demonstrators in the fruit-growing districts of England, men with a practical knowledge of the wholesale and retail trade. There was, he said, a great future for English vegetables and fruit if the growers really knew what the public wanted. At present the English produce was badly packed, and the growers had not a practical knowledge of the requirements of the market. Foreign fruit was selling, not because it was of better quality, but because it was put up in better style. Both Departments had promised to consider the question, but had done nothing yet.

The Gardeners' Company.—At the meeting of the Court of Aldermen, held at the Guildhall on Tuesday, a petition was presented by the Gardeners' Company, applying for an increase to their number of Liverymen. The Master (Sir Horace Marshall), the Wardens (Mr. G. R. Blades and Mr. G. Shead), and the Clerk (Mr. E. A. Ebblewhite) attended in support of the petition, and stated that the increase suggested was from 60 to 150, that the last increase was granted twenty years ago, and that the Duke of Teck and other eligible Freemen were anxious to take up their Livery in the Guild. The petition was referred to the General Purposes Committee for consideration.

Hybridisation of Orchids.—At the fortnightly meeting of the Northumberland Coast Club, held on the 7th inst., Mr. H. J. Chapman, of the Oakwood Gardens, Wylam-on-Tyne, gave an instructive lecture on "Orchids," which was illustrated by a series of coloured slides. In the course of his lecture, Mr. Chapman stated that a great industry had been created in the raising of orchids since the publication of Darwin's views on the fertilisation of orchids about the year 1850. It was in 1852 that Dr. Harris, a surgeon, of Exeter, suggested to the late John Dominy that he should experiment on the lines laid down by Darwin. The result was that the first seedling was raised artificially in 1856. Until within a quite recent date, we had to depend almost entirely upon the expensive process of importation for the supplies of orchids, but so rapidly had hybridisation developed that the home supplies of seedlings has practically done away with foreign trade, the price of the plants being so greatly reduced that all orchids worthy of culture are now within reach of the amateur.

SCOTTISH AND GERMAN METHODS OF FORESTRY.

The above title is not of the writer's choosing, but, as he has been allowed a free hand in dealing with the matter, it may do as well as another, and, after all, "a rose by any other name would smell as sweet," though readers of the Gardeners' Magazine hardly require to be reminded that not every rose is fragrant.

Method, in the dictionary sense of orderly arrangement, is very much wanting in Scottish forestry, in a national sense, compared with German forestry. This must not be considered as a slur on Scottish foresters, or proprietors either; what it is desired to point out is the want of uniformity, and lack of system, in matters pertaining to forestry.

The writer has been repeatedly asked, "Is there as much difference between German forestry and our own, as we are led to believe?" The answer has invariably been in the affirmative, of course, with a qualification. Taking first things first, Scottish foresters have probably little to learn about the raising of seedlings in the nursery, as, besides the many excellent public nurseries throughout the country, most estates have a nursery of greater or lesser extent, where experience can be gained. It is when dealing with transplanting, with a view to the production of timber, that the Germans show the way. While the Scottish forester is transplanting in the home nursery, with a view to raising plants that will have an effect when planted out, and have some chance of surviving the attacks of ground game, the German forester is planting direct into the forest. He generally raises his seedlings *in situ*, in temporary nurseries, and is thus able to stock his area very cheaply.

Unskilled labour is probably a little cheaper in the German forest area than in Scotland, and a little more care is taken in lifting and planting than is usually taken in Scotland. They grow the seedlings fairly thinly on the ground, and when lifted a fair proportion of the soil is allowed to remain on the roots, and within a comparatively short time the plants are in their new position. They are not "notched" in, as, alas! is the case on only too many properties in Scotland, but properly planted in well-prepared pits, with prepared soil added in some cases. Close planting has been synonymous with German forestry, popularly, but this is not altogether correct. The German forester knows that the struggle for existence does not begin so soon in an artificial plantation as it does in a natural one, and that even of what he plants only a small proportion take part in the final struggle, and form the ultimate crop.

Natural reproduction, as a means of stocking certain areas favourably situated, is made use of, but probably not to the same extent as formerly. The German forester is so systematic that he will not run the risk of a bad seed year or two upsetting his rotation. In Scotland some very fine examples of natural regeneration exist, but, with a few exceptions, they are more the result of chance than of good guidance. The mixtures that have found favour in the past in Scotland are, with few exceptions, not tolerated in Germany, and undoubtedly the growing of the different species and varieties in groups, masses, or pure forest, becoming more prevalent in Scotland, is a step in the right direction. The tending of the growing crop is very much simplified where the system of planting in groups or masses is adopted and early thinning is a simple operation, demanding only the removal of dead, and, probably dying, trees, instead of an intricate business of trying to suit the varying requirements of Scottish mixtures, as to space, light, air, etc. The writer is well aware of such points as differences in soil, altitude, aspect, etc., which occur within a small compass sometimes, and of the danger from fungoid diseases, insect attacks, windfalls, etc., in pure forests, but these drawbacks disappear, to a large extent, where something after the German system is adopted. There is a danger in allowing a crop to thin itself, as in some cases the individual stems become so attenuated as to be unable to support themselves. Nature demands that a certain balance be maintained between stem and leaf surface, varying according to the several species. While upholding the German system, no one would despise the British oak produced under a different system, in days gone by, to meet certain requirements, and it is further admitted that for certain purposes hardwood grown with a large amount of light and air is infinitely superior to that grown in close canopy, but, speaking generally, the German method produces cylindrical stems of high commercial value, the Scottish tapering stems being of low value.

Pruning is a thing almost unheard of, and unnecessary, in Germany, and it follows that it means a greatly reduced outlay on the crop, and ultimately a finer quality of timber. By the Scottish method of early thinning pruning has been rendered a necessary evil, and knotty timber of poor quality the product.

The maintaining of proper canopy during the rotation has been given much thought in Germany, and as the preservation of the soil depends so much on the density of the canopy, it well repays whatever outlay may be found necessary to maintain it. The value of soil preservation is not very well recognised in Scotland, where there is usually an abundance of moisture, but moisture is not everything, and undoubtedly the soil deteriorates quickly under a thin crop. Underplanting, particularly oak, has been proved to be of great value in some of the German forests, and on what had been naturally poor soils, the rotation period has been lengthened considerably by the adoption of this practice, in many instances. In Scotland thin crops are mostly the rule, and in trying to lengthen out the rotation period most of the hardwoods are allowed to stand too long. Thousands of what might have been useful timber trees, under proper treatment, are to-day dying, their end being hastened by the help of numerous fungi. This does not refer to arboreal specimens and ornamental plantations only, but to many of the woodlands that are certainly of some value, but nothing approaching the value they would have been had they been grown under anything like the German system.

Probably a great advance has been made during the last twenty-five years or so in the way of educating the Scottish forester, but there is a lack of uniformity of ideas as the result of that education, which every individual has been allowed to obtain as best he was able. The German forester has been in a vastly superior position for generations back, having every facility for education and research placed at his disposal by a beneficent and paternal government. The German nation, as a whole, seems to be aware of the value of its timber, as a national asset, not merely in a financial sense, but as a means of helping an industrious race at home. It is to be hoped that the educating of the British nation, that has been going on for some time, through the medium of the Press, will be continued with increased vigour, if possible.

The output per acre per annum has increased considerably during the last few decades by reason of the systematic management and control exercised in Germany, even over private forests, and even if State afforestation is not within measurable distance, there is an area under wood in Scotland sufficient to warrant a certain amount of State assistance and control. Placing regular quantities of timber upon the market has done a great deal to raise German forestry to the place it now holds in the nation's well-being. This it could not do for long without systematic control, for, unlike countries with vast natural forests, Germany must look to the creation of forests as well as to their exploitation. The spasmodic attempts that are made to market Scottish timber does a great deal to foster foreign competition, and delays the day of better things for forestry at home.

In comparing Scottish and German forestry the writer has endeavoured to point out some of the things that appear to him to be of most outstanding importance, but it must not be considered that he is pro-German, for, while he has shown something that might be emulated, he would not advocate a wholesale adoption of German methods. He is patriotic enough to admit that there is good forestry to be seen in Scotland, and sanguine enough to believe that it will go on improving. The Scottish forester has done his part, by travel and otherwise, to widen his view, and now the time has surely come for the nation to do its part in bringing order out of chaos.

Sylva.

HEDGEROW TIMBER.

Nothing adds so much to the charm of English scenery as the hedgerow timber, and in passing through the country, even the casual observer can hardly fail to note that the characteristic charm of rural England is largely due to the stately elms, majestic oaks, and other trees, as a rule, plentifully sprinkled along the hedgerows, clustering around the village church, or sheltering some old manor or farm house.

Many parts of the country, if cleared of its field timber, would have a bare, and often rather bleak, appearance, and, unfortunately, there is a tendency in some places to over thin, or even completely clear it. On the other hand, too much timber should not be tolerated in the hedges, and where, for various reasons, it has been allowed to accumulate to too great an extent, it is desirable, in the interests of good management, to have heavy fellings, so as to reduce it to within reasonable limits. There is sometimes good reason for the hostility of many farmers to hedgerow trees. Unsuitable species, such as those with far-reaching surface roots, or neglected, rough, and low-spreading trees, pertaining more to the gooseberry habit of growth than to that of a tree, suppressing hedges and farm crops alike, are very much out of place on the highly-cultivated land they often occupy.

These, often practically beyond pruning, should be cleared away, and their places taken, where desirable, by young, well-grown trees. A tall, well-shaped tree, with a fair length of clean bole, is not only more ornamental and more in keeping with its surroundings on well-farmed land, where it does the minimum of harm, but also worth a great deal more when felled than the short, badly-grown specimen.

Æsthetic effect, and shelter, combined with the production of the most profitable class of timber, and the chief purposes for which hedgerow timber is grown, and to satisfactorily attain these objects without unduly interfering with the productivity of the soil for agricultural purposes, the necessary good management must begin with the planting of the trees.

In selecting trees for hedgerow planting only those of an upright habit of growth, and more or less deep rooting, should be chosen, avoiding at the same time the heavy shade-bearing species. A little more latitude is, however, permissible on pasture than on tillage land. Among the most suitable species are the Cornish Elm (Ulmus cornubiense), which has an erect, compact habit, requiring practically no pruning, to confine it to a close upright shape. It is also very effective as an ornamental tree, and deserves to be far more extensively planted than it is at present. The common English Elm (Ulmus campestris), also makes an excellent hedgerow tree. Like the Cornish variety, it is very upright in habit, though in a much less degree. It is one of the most valuable and common trees found in the hedges, especially in the south and west Midlands. In Worcestershire and parts of the adjoining counties it abounds in almost every fence on the deep sandy and clayey loams, where it grows naturally from root shoots or "suckers." The finest trees, with timber of first-rate quality, are raised in this way. When planting the hedges it is only necessary to leave a number of the young shoots, produced in the above manner, to fill the gaps caused by felling operations. It is impossible to purchase seedlings of the true English elm, as its seed never ripens in this country, and trees can thus only be obtained by grafting, or by transplanting the suckers from the hedgerows.

The English Oak (Quercus robur) is well known as one of the most ornamental and best all-round trees for hedgerow planting on deep loamy and clayey soils. It stands pruning well, and is easily kept in good shape, while as a timber tree it needs no recommendation.

Black Italian and Old English Poplar (Populus monilifera and P. nigra), on wet and clayey soils, with their long stems, usually free of branches for a great height, are not only very effective, but also valuable timber trees, owing chiefly to their very rapid growth. The black Italian poplar grows faster, and to a much greater size, than the old English variety, and is the better timber tree of the two.

The Lombardy Poplar (P. fastigiata), with its conspicuous fastigiate growth, is not the least harmful to crops, and stands out prominently in the landscape. Planted judiciously it produces a pleasing effect. It is, however, quite valueless as a timber producer. The graceful Birch (Betula alba), one of the most accommodating of trees, growing almost equally well on wet clayey or on light, poor sandy soils, is another useful tree for hedgerow planting, its light foliage hardly affecting fences or field crops while there are few situations in which it is out of place.

The Crack Willow (Salix fragilis) can often be advantageously used by the margins of streams or water-courses. The Maple and Sycamore (Acer platanoides and Acer pseudo platanus) are both important hedgerow trees, but are rather inclined to a more spreading habit than any of the foregoing species, requiring more attention in the way of pruning in the early stages. The sycamore is the best of all hardwoods for planting on exposed situations, and on pasture land affords excellent shelter for farm stock. Coniferous trees generally are not at all suitable for field planting, the only exceptions being the larch and Scots pine, which, in some situations, such as high-lying, more or less exposed, grazing land, are both ornamental and useful shelter trees.

The foregoing list, while giving a sufficient variety both of form and colour of foliage, provides for the requirements of most soils and situations. It is most important, if the work is to be successful, that the right trees are planted on the right soils. No amount of care in the way of pruning will produce long clean oak or elm on light shallow land. Unsuitability of soils is the chief cause of a great deal of the badly-grown, short, bushy trees, of no value, so frequently met with.

For hedgerow planting well-rooted trees about six to eight feet high will be found most suitable, as their heads will be beyond the reach of most farm stock, while, if too large, they are more difficult to establish, and have a tendency to a spreading and deformed growth. Early and repeated pruning is also necessary to produce the right class of hedgerow trees. The top shoot must always be kept clear, and no side branches allowed to encroach on its lead, while the lower branches must be fore-shortened to prevent them spreading too far. As the tree gains in height the lowest branches will be removed from time to time, and thus the head of the tree will be gradually raised, until a clean length of stem of at least fifteen to twenty feet is obtained. Hedgerow trees should not be pollarded, a practice very common, evidently, in past times.

Instead of being a source of annoyance to the farmer, well-managed hedgerow timber will usually be of considerable benefit to him by providing shelter to his stock from the cold winds of winter and the hot suns of summer.

J. Braid.

PROFITABLE WOODLANDS.

One of the questions a proprietor of an estate very probably will put to his agent or forester, when planning planting operations, is, "Will it pay me to undertake this work?" Now, this is a very difficult question to answer, as so much depends on the suitability of the soil and climatic conditions to meet the needs of the variety of trees that are to be planted, and, not only that, but to have a chance of making any commercial profit out of a plantation the after-management, which is often at fault, must be of the best.

In a great many of our maturing woodlands at the present day we often find that they are carrying only half the volume of timber they ought to have, perhaps owing to the old-fashioned idea of severe thinnings which was customary in my younger days; sometimes a sporting landowner will try to improve the undergrowth for forming game cover; possibly a demand has arisen locally for a certain class of thinnings, and the growing trees have been cut indiscriminately.

A case of the latter came under my notice only a few days ago, when I visited some plantations on an estate in Lincolnshire. The age of the trees was about twenty-eight years, and there were alternate rows of larch and Scots pine, and I found that a few years ago nearly every tree in the larch rows had been cut out merely because a demand for larch thinnings had arisen locally, and the result now is that what would, ten years ago, with judicious management, have made a profitable wood, will now be a financial failure, from a forester's standpoint.

In forming hardwood plantations my experience is that, with suitable soil, oak and ash are the best commercial trees to plant, and in forming a hardwood plantation one should not mix many conifers amongst them, as there is more chance of rearing a decent hardwood plantation by planting three hardwoods to one conifer than the reverse, which is so often done in this country, so that we find the hardwoods eventually dominated by the so-called nurses. The most suitable soil for the Common Oak (Quercus pedunculata) is deep fresh clayey loam, while if the soil should be of a drier and sandy nature the Sessile Oak is the most suitable. I often wonder that the nurserymen do not make a distinction and grow Quercus sessiflora more than they do. On the Hereford portion of this estate, where the soil is a marly clay on the limestone, nearly all the oak woods and coppices are of this oak, and, though at an altitude of 600 to 800 feet, it not only grows straighter, but makes far quicker growth, and, commercially, we get quite as good demand and prices for its timber as for the other, although growing in an inconvenient district for removal. This exceptional year a large crop of acorns of grand quality has been produced, and should be taken advantage of by all who wish to raise strong seedlings.

Ash is a profitable timber if grown on deep, light, loamy soil, which should not be waterlogged; in its younger stages the thinnings of ash are in very good demand. I have found that for forming ash plantations about 75 per cent. of ash should be mixed with about 25 per cent. of spruce and larch; this is a very good mixture, using strong stout ash plants four to five feet high, and firs, say, two to two and a-half feet high. At the age of thirty years the firs may be removed altogether if the crop of ash is close enough. If ash is planted on wet, low-lying land of a boggy nature, which is too often the case, it will eventually, in its later stages (if it survives the disease, Nectria ditisimma), be found to open black-hearted, and be very little use for commercial purposes. There is no foreign ash imported that can compare to our home-grown wood for toughness and durability, and I believe ash will be one of the best commercial timbers of the future, and good sound trees will command higher prices in the near future, for ash is getting to be one of the most scarce of our hardwoods, and should be planted more largely than it has been in recent years.

While on the subject of hardwoods I should like to make a few remarks on coppice woods. It is a well-known fact that on many estates this class of forestry is far from a profitable one. No doubt many thousands of acres of coppice woods are being worked at very little, or no profit, owing to the very poor demand for oak underwood. I have for the past twelve years, where falls have come in on this estate, cut only the very oldest standard oak, and left all straight, clean-growing poles, varying from 120 to 200 per acre, the latter number chiefly in the sessile oak woods. I believe, in the Midlands, we have a better chance of forming these highwoods, as there always seems far more strong stools and maiden oaks than are found in the southern and eastern counties, where one will often find only a few large-headed oaks per acre, and none, or few, growing poles coming on to take their place. It is advisable, in the case of plantations similar to the latter, to clear, fell, and replant with whatever tree is suitable, and likely to be profitable.

SPECIMEN TREES FOR PARKS AND GARDENS.

With such a wealth of material at hand it is difficult to understand why use is not made of more exotic trees for the adornment of our parks and pleasure grounds. We meet with the elm, oak, beech, and lime on every hand so frequently that, while admitting they make splendid specimen trees, their too liberal use is apt to become monotonous. Even if we do not go so far as this, it will be readily admitted that were a wider selection of subjects planted parks and gardens would be infinitely more interesting. At the same time, the addition of variety to a park, assuming it is planted with taste, must add considerably to its beauty. In years gone by a few trees, other than those commonly met with, have been planted up and down the country, but these are, as it were, only a leaf in the forest. But what of the places where these trees have been planted? How interesting they are. Take Syon House, for example. How very attractive the grounds are with their unique specimens of Cladrastis tinctoria, Corylus colurna, Celtis occidentalis, Juglans nigra, Liquidambar styraciflua, Liriodendron tulipifera, and Zelkova crenata.

THE CEDAR OF LEBANON (CEDRUS LIBANI).

Two splendidly-developed specimens at Addington Park, long the Surrey residence of the Archbishops of Canterbury.

Chestnuts and Oaks.

The common Horse Chestnut (Æsculus hippocastanum) is well known as our best flowering timber tree. Those in charge of public parks find the fruits a serious drawback to this tree in autumn, and for the same reason its use as a street tree is not desirable. There is an easy remedy however, and that is to plant the double variety, which is equally floriferous, but does not mature fruits to tempt the schoolboys. The Red Horse Chestnut (Æ. carnea) is a free-flowering, round-headed tree, of moderate height. A little-known hybrid between these two chestnuts is Æ. Plantierensis. This has delicate pink flowers, and, being vigorous in growth, is recommended for extensive planting in public parks, as no fruits are produced. The Indian Horse Chestnut (Æ. indica) is of considerable value, as it blossoms in July, a season when there are comparatively few trees and shrubs in flower. The rich green leaves are a feature of the tree, and remain in good condition until most of the other chestnuts are bare. At a distance, when in flower, the tree resembles the common chestnut, but closer inspection shows a longer raceme, and the individual flowers of a similar colour, but less closely packed.

Several oaks are worthy of attention in large parks, while the Holm, or Evergreen Oak (Quercus ilex) is the best large evergreen tree we possess, excluding conifers, for planting in the south. As a rule, the trees grow to a moderate height, with a wide spread of branches. In Wales a tree is recorded with a diameter of 98 feet. On the other hand, there is a tree at Syon House 90 feet in height. Quercus rubra is the freest growing of the American oaks. It has large leaves, which turn reddish-brown in autumn. For autumn colour Q. coccinea is far superior, but this tree is not so bold and vigorous in growth. Waterer's Scarlet Oak (Q. coccinea var. splendens) has deeper and richer-coloured leaves than the type in autumn. Other oaks worthy of attention are Q. cerris, Q. conferta, and the Lucombe Oak, Q. lucombeana.

Conifers.

For effect, especially in winter, it is necessary to have a few conifers dotted among the deciduous trees. Almost every park or garden of any size possesses a few specimens, the most popular being the three Cedars, C. Atlantica, C. Deodara, and C. Libari, the Scotch Pine (Pinus sylvestris), Cupressus Lawsoniana, the common spruce, the Douglas fir, and Sequoia (Wellingtonia) gigantea. To these may worthily be added the Umbrella Pine (Sciadopitys verticillata), a remarkably distinct and interesting Japanese conifer; Picea Bungeana, the Silver-laced Bark Tree of North China; Picea Omorica, a Servian species, and Pinus Peuke, from Bulgaria.

Limes and Maples.

The common lime has been freely planted in the past, but it is very liable to the attack of aphis. In public parks seats under the trees are objectionable owing to the filth from these insects. Tilia dasystyla, a Caucasian species, is, for some unaccountable reason, avoided by aphis. It forms a large, handsome tree, with deep green leaves and fragrant yellow blossoms, which open several weeks later than most of the common limes. In some catalogues this is listed as T. euchlora. Here and there a few good specimens of the Tulip Tree (Liriodendron tulipifera) are to be met with, but it is far from being common. Tall and noble in appearance, the tulip tree grows to a height of 80 to 100 feet. The flowers are borne freely on large trees during the summer, but are not very conspicuous, being more or less hidden by the leaves. Their colour is yellow and green, tinted with orange, and the shape is not unlike a small tulip bloom, which gives the tree its popular name. In North America the tree is called the saddle tree, the shape of the leaf resembling a saddle. In autumn the tulip tree is very striking when the leaves change to a glowing golden-yellow tint. A second species, L. chinense, is of recent introduction from China. The leaves of young trees are very ornamental, but, as with other trees, the leaves are much smaller on mature specimens. When collecting for the Messrs. James Veitch and Sons, in China, Mr. Wilson met with a specimen of this species fully 60 feet high.

Many of the Acers are very ornamental, and the larger-growing kinds are notably fast in growth. The Norway Maple (Acer platanoides) is fairly common, forming a large tree 60 feet or more in height. Two varieties are deserving of attention from planters: A. p. Schwedleri, the young leaves of which colour a beautiful red in spring; and A. p. Reitenbachi, which has foliage that for some time previous to falling in autumn is rich red. The Red Maple of the United States (Acer rubrum) forms a large handsome tree, 50 to 70 feet in height. This is first noticeable in early spring, when loaded with small red flowers, the character from which it gets its name; in some parts of the country the leaves colour well in autumn. A. macrophyllum is a Californian tree, and one of the handsomest of the family. The five-lobed leaves often measure ten inches to a foot across. In May the tree is bright with yellow racemes of flowers, which are succeeded by numerous fruits, that attain to a large size as autumn approaches. The average height is from 60 to 80 feet. The variegated Acer negundo is a common plant in this country. The same cannot, however, be said of the species Acer negundo, which is a distinctly handsome tree, with pinnate leaves. In habit it is a wide-spreading tree, 30 to 40 feet of more high. A. dasycarpum forms a tree of fair size, the twiggy branches of which have a distinctly pendulous habit. It is appropriately named the silver maple, because of the colour of the undersurface of the leaves, the beauty of which is best seen when the twigs are gently swaying to and fro in a breeze.
A. Osborne.

(To be continued.)

THE SCARLET OAK (QUERCUS COCCINEA).
A handsome species, with finely-cut leaves, which assume a bright red colour in autumn.

Gloriosa virescens grandiflora.—Since the introduction of the gorgeous Gloriosa Rothschildiana, a greater amount of interest than formerly existed has been shown in the different members of the genus. Gloriosa virescens, which used to be known as Gloriosa Planti, has much broader flower segments than those of the better-known Gloriosa superba, and the flowers are reddish, while those of grandiflora are yellow.—W. T.

PLANTATIONS FOR LANDSCAPE EFFECT.

Although when trees are to be grown for profit the principal consideration has to be the best method to adopt for obtaining the greatest amount of revenue from a given area in a certain time, and matters of more or less æsthetic interest have to give place to the prosaic one of pounds, shillings, and pence, a great deal can be done towards beautifying the countryside, without interfering with the economic side of forestry, by the thoughtful disposition of plantations and a due regard to their general outline. As an instance of what is meant, attention may be directed to the many round, square, or rectangular plantations, which may be seen throughout the country dotting the crowns or slopes of hills, and they are to be contrasted with other woods where the planting has been done in such a manner that it follows the contour of the land. Instead of gaunt blocks which might have been turned out of moulds, we have natural-looking plantations, with undulating margins, ranging from varying heights at the lower elevations to the summit of the hill; agricultural and forest land uniting without any hard line. By such a method of planting it is also possible to take better advantage of the shelter provided by plantations than when the planting has been confined to formal blocks, for here and there a glade may be allowed to run for some considerable distance into a wood, thus providing a pasture sheltered on three sides, whilst even small marginal undulations are always taken advantage of by stock in cold weather.

Fencing operations are, perhaps, made easier when formal blocks are planted, for in the case of wire fencing, straining is more easily accomplished in the case of long, straight lines than when an irregular outline occurs. In the event of very large plantations being formed, however, this difficulty need not be seriously considered, for arrangements could easily be made to avoid any extra expense, whilst in the case of small woods the difference in expense between a straight and undulated fence would not be a very serious matter.

It is also possible to do a good deal towards making the country beautiful by the careful selection of the kinds of trees planted, for, although it is only natural that the kind of tree which is likely to give the largest margin of profit should be the one selected for general planting, opportunities may occur through a local difference of soil or exposure for the introduction of other species. In such instances the different kinds of trees should be allowed to meet without any hard and fast line, as though a gradual change had taken place from one kind being the dominant feature to the other. Then, again, the inclusion of various low-growing trees or large shrubs about the outskirts of plantations gives an air of interest to what would otherwise be unbroken lines of one, or perhaps two, kinds of trees, while at the same time additional shelter is provided. Thus the common Spindle-tree (Euonymus europæus), Wayfaring-tree (Viburnum Lantana), Guelder Rose (V. opulus), Blackthorn (Prunus spinosa), Holly (Ilex aquifolium), and Buckthorn (Rhamnus cathartica) are all useful and suitable subjects. In the Chilterns one frequently sees the common cherry growing amongst beech timber. During the flowering period the cherry is most effective, while from a financial aspect the wood does not suffer, for good cherry is as valuable as good beech.

It is, however, in parks and woods in the immediate vicinity of a mansion that per-

J. R. PEARSON & SONS, LOWDHAM, Notts.

haps the greatest care has to be exercised in the selection and disposition of trees, especially if spinneys or plantations are to be formed with a view to their yielding profitable timber at some future time. For this purpose a general mixture of trees such as sometimes obtains is not to be encouraged. Such a mixture has the appearance of the sweepings of a nursery and is rarely effective. When a great many different kinds of trees are grown together, people naturally want to get amongst them to examine them ; therefore it is desirable that they should be given every facility for developing into perfect trees, both as regards heads and trunks, whereas for sylvicultural purposes the trunks are allowed to develop at the expense of the heads, and on account of this, the heads are often of a nondescript character. Two or three kinds of trees may, however, be used to form a plantation, but they should be trees which blend with each other ; for instance, it would be unwise to form a mixture of green and variegated foliage trees or of copper beech and common oak. If these coloured leaved trees are to be used, use them alone. Again, such things as Araucaria imbricata and Sequoia gigantea are hardly the subjects to mix with British trees, though there are other exotic conifers which would not look at all out of place.

The judicious planting of the outskirts of park plantations with showy flowering or fruiting trees is commendable, providing trees of a garden nature are not included. Such things as Pyrus aucuparia, P. aria, P. malus, P. communis, Cratægus species, Robinia pseudacacia, Prunus avium, Ilex aquifolium, and the common laburnum are suitable subjects. Where colour effects are desired, plantations of golden poplar, copper beech, white poplar, or golden or silver elms may be introduced, but they must be very carefully placed in order that they will not strike a discordant note among trees of a more typical character. Colour of natural foliage demands attention in ornamental planting, for the leaves of some trees have a very sombre look ; therefore, without something to relieve them, their effect is depressing. The yew and Austrian and Corsican pines are cases in point. It is, however, possible to brighten up what would otherwise be a dismal wood by the introduction of clumps of trees with more cheerful foliage, and by planting the outskirts of groups of trees with species having brighter coloured leaves. The outskirts of decorative clumps of trees are not supposed to provide good timber trees, that is left for the inner parts of the wood ; therefore, advantage can be taken for the introduction of subjects which are more profitable for shelter and ornament than for timber.

In addition to large clumps of trees, it is often necessary to plant small clumps in a park. These, as a rule, ought to be formed of one kind of tree each, so that all may grow together to form a well-balanced group, or that all may be removed save one, after they have done their duty as nurses and drawn that one up, for many of our best proportioned trees have been obtained by leaving those which have been drawn up in a clump or wood with plenty of room for branch development after they have attained a considerable height among other trees. For the kinds of parks usually attached to large domains it is, as a rule, inadvisable to introduce trees of a garden character, the best results being obtained by a judicious blending of clumps and isolated native trees or exotics, such as Douglas fir, larch, chestnut, silver fir, or others of a similar character. Formal shaped clumps must be avoided, and the whole system of planting made to look as natural as possible.

Many very happy results of park planting are apparent throughout the country, but in some places there appears to be a tendency towards a too formal style. A very natural-looking park is to be seen around a mansion in the vicinity of Flodden. The trees are in irregular-sized groups, with considerable areas of open grass land intervening. It is said that the groups of trees were planted originally to represent the disposition of the troops at the battle of Waterloo. Whatever the original idea was, the result presents a delightful landscape effect.

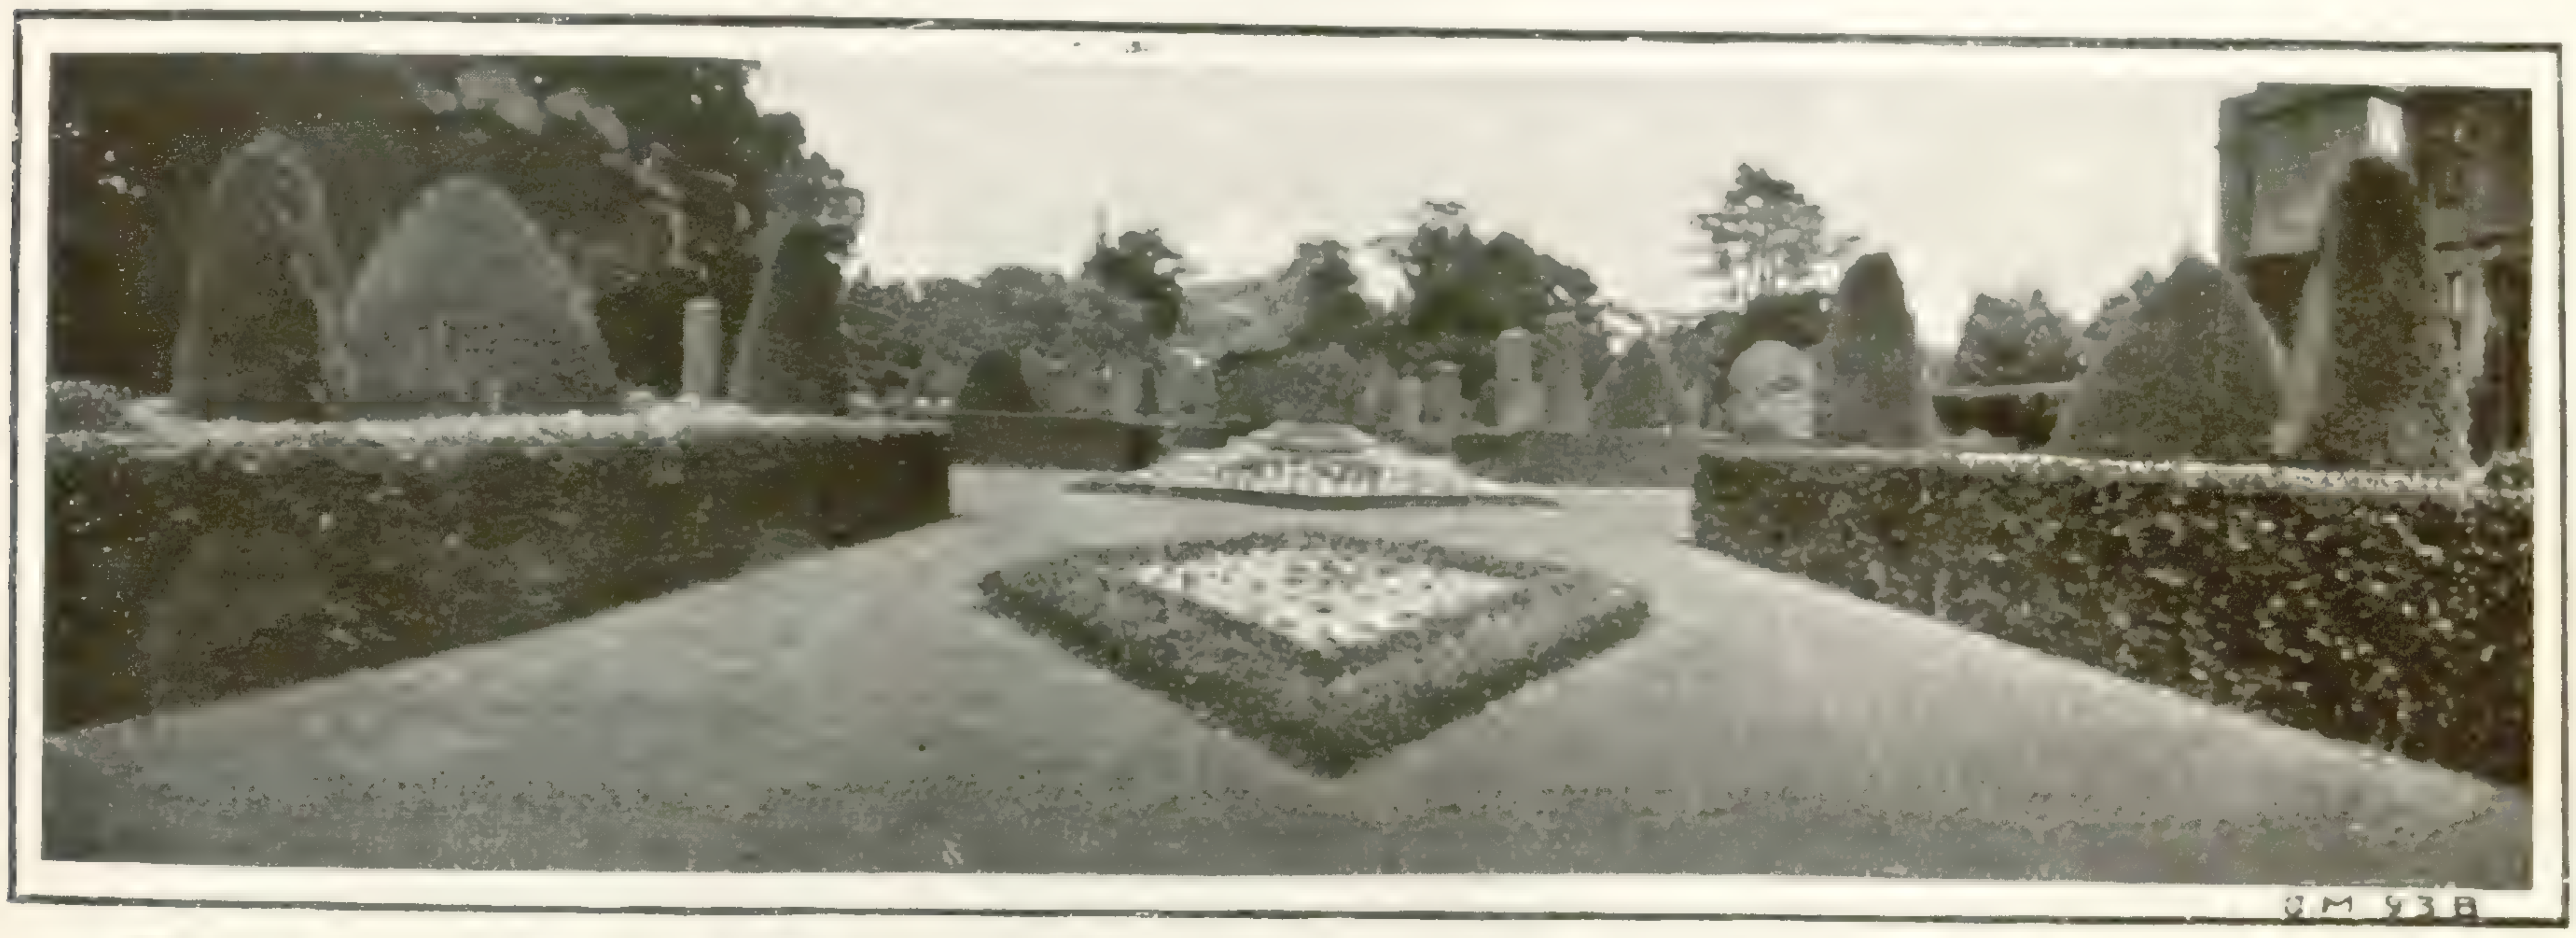
Although in many cases it is inadvisable to form too great a mixture of trees for landscape effect, there are cases where it may be advisable to introduce clumps of many kinds of trees for experimental purposes. Then groups of such kinds as the Tulip-tree (Liriodendron tulipifera), Maidenhair-tree (Ginkgo biloba), Black Walnut (Juglans nigra), caryas in variety ; Atlas Cedar (Cedrus Atlantica), Tree of Heaven (Ailanthus glandulosa), Red Gum (Liquidambar styraciflua), Japanese Cedar (Cryptomeria japonica), deciduous cypress (Taxodium distichum), Lawson's cypress (Cupressus Lawsoniana), etc., might well be planted.

Where the production of timber is not the first question in view, very effective plantations may be formed by planting some special kind of tree, any of the above, for instance, wide apart, with nurses in between, so that the nurses can be taken out eventually, leaving the special trees with ample room to develop to their full size, so that each tree will stand clear of its neighbour. Such groups have a very ornamental effect, for the nurse trees ensure height, then comes a good development of branches, and each tree is a perfect specimen, though, of course, the wood is less clean than that which has been grown under purely sylvicultural conditions.

Kew. W. Dallimore.

EVERGREEN HEDGES.—I.

Much of the charm and attractiveness of a country landscape lies in the apparently haphazard manner in which a large area of land is divided into separate plots or enclosures, for the greater convenience of sport, pleasure, or cultivation. Such boundary and intersecting lines, or divisions, must, of necessity, to fulfil their purpose, be very prominent, as well as useful, objects. Wood, stone, iron, and living plants are all requisitioned for the purpose, according as each, or any, may be most adaptable or easily procurable in the immediate neighbourhood. Other things being equal, living plants are by far the most ornamental, and, with skill and care expended upon their cultivation, may easily be made the most satisfactory, as to effectiveness and length of service.



FINELY-FORMED AND ADMIRABLY-KEPT YEW HEDGES AT CONDOVER HALL, SHREWSBURY.

It is occasionally remarked that the proper treatment of living fences—hedges—is, to a great extent, a lost art. There may be a grain of truth in the assertion, but I think the cause is more likely to be found in the greater demands that are now made upon the supervisor and his staff of workmen in other departments of the garden, notably plant and flower culture, both under glass and in the open air, and the necessary trimming and tending of hedges is neglected, or the work, if done, is deferred far beyond the time most suitable for its accomplishment in a thorough manner, and the greatest benefit to the health and longevity of the plants.

Evergreen hedges, as may readily be surmised, are most in favour near the mansion ; not absolutely so because of their well-furnished and pleasing appearance at all seasons, but owing nearly as much to the shelter, comfort, and sense of security they afford in the most inclement and cheerless period of the year. Evergreen species of plants suitable for the purpose are now more numerous than was the case when many of the existing hedges which adorn the environment of many a stately home were planted. These, more often than not, are of the yew tree, than which there is no species more lasting or suitable for forming an almost impenetrable wall of greenery, that will withstand storm and strees, and prove an object of grace and beauty for several centuries.

The Yew.

This is of slow growth, a point which, in some respects, constitutes its chief merit, for, as already stated, a hedge once formed, of sufficient height and breadth for its purpose, can, by the means of an annual trimming, be kept to a regulation shape and size for a very long period. When preparing a site for planting a trench fully three feet in width and two feet or more in depth, breaking up the lower strata deeply before returning the excavated soil is required. If poor in quality dung or leaf-soil may be mixed throughout to a moderate extent, and, what is still more important, a fair amount of lime to soils deficient in this commodity must be added. The yew will thrive in most soils and positions, and withstands shade from overhanging trees or contiguous buildings better than any other evergreen. The plants, at the time of insertion, should be about two feet in height, and have been transplanted yearly to encourage the formation of small fibrous roots. Pruning, with the exception of the removal of a rampant shoot here and there, will not be required for at least two years from time of planting. It is best done in the spring months, and watering should be well attended to for the season thereafter. Before pruning proper is set about consideration should be given to the situation, and a decision arrived at as to the contour of the future hedge. To harmonise with an ancient mansion or its appurtenances straight perpendicular sides, with flat top, is probably the best. As a first step towards this, with sharp shears clip both sides evenly, and reduce the top growth in moderation, the standard of size being set by the weakest part, if such there be. Where two clippings can be given each year the latter parts of June and August are most fitting, but, if only one, the latter period is preferable, the growths then being matured.

VIBURNUM RHYTIDOPHYLLUM.

A distinct evergreen shrub, with handsome foliage, and bearing, at the points of the growths, corymbs of yellow-white flowers, which are succeeded by deep red berries.

The Holly.

This is an excellent plant for hedges, more especially where such are wanted for ornament and shelter, rather than utility. The spinous foliage is, in this respect, of some assistance in resisting the onsets of cattle or other would-be intruders, but several years must necessarily elapse after planting ere the branches attain sufficient rigidity to be thoroughly effective in this way, while anyone having had much experience with holly knows the difficulty that ensues when a gap becomes a reality. The some preparation of site as detailed for the yew holds good, but if the soil is not fairly rich, liberal additions of manure or good loam should be added, and any depression of surface in the line, whereby water might accumulate to the detriment of the plants must be drained. A rich, warm, and moderately dry soil is most suitable. As an aid to this, upon shallow soils or very moist situations, the digging of a small trench or ditch alongside the prospective line of fence, laying the soil thus excavated in such a way that a bank, from one to two feet in height, is formed, into which, when well consolidated, the roots of the plants may be inserted, is of great assistance. An oval-shaped hedge is preferable for the holly, and severe pruning should be deferred for a considerable time to enable the roots to obtain a good grip of the soil. James Day.

ORNAMENTAL FRUITING TREES AND SHRUBS.

Now that the planting season is near at hand, the value of ornamental fruiting trees and shrubs must not be overlooked. A tree or shrub may be beautiful when in flower or again in the autumn, with its changing tints of foliage, yet the brilliant fruits and berries are, in many cases, not taken into consideration. In many instances, aucubas are planted for their foliage alone, yet if a few male plants are mixed with them, a glorious crop of berries will result. The same method must be adopted with the sea buckthorn, i.e., a few male plants must be planted to provide pollen.

The Mountain Ash (Pyrus aucuparia) is familiar to everyone, with its large bunches of scarlet berries, and the various hollies are too well known to need mention here. The common Dog rose (Rosa canina) makes a bright picture in the hedgerow, and some corner in the wild garden should be found to accommodate it on account of its fruits. R. rugosa has fine hips, and it is an excellent species for grouping in the shrubbery. The cotoneasters should be largely planted, on account of their free berry bearing propensities; C. frigida is the tallest growing, and deserves to be more popular than it is at present. It carries large, flat heads of bright scarlet berries, and is a striking object in the autumn. Others worthy of mention are C. horizontalis, C. rugosa Henryi, C. microphylla, C. Simonsi, C. pannosa, and C. applanata. Viburnum rhytidophyllum is highly attractive, with its foliage and berries, the latter being borne in flat bunches at the extremities of the shoots. V. Henryi and V. phlebotrichum are also good. The peculiar racemes of fruit of Leycesteria formosa makes it an interesting shrub.

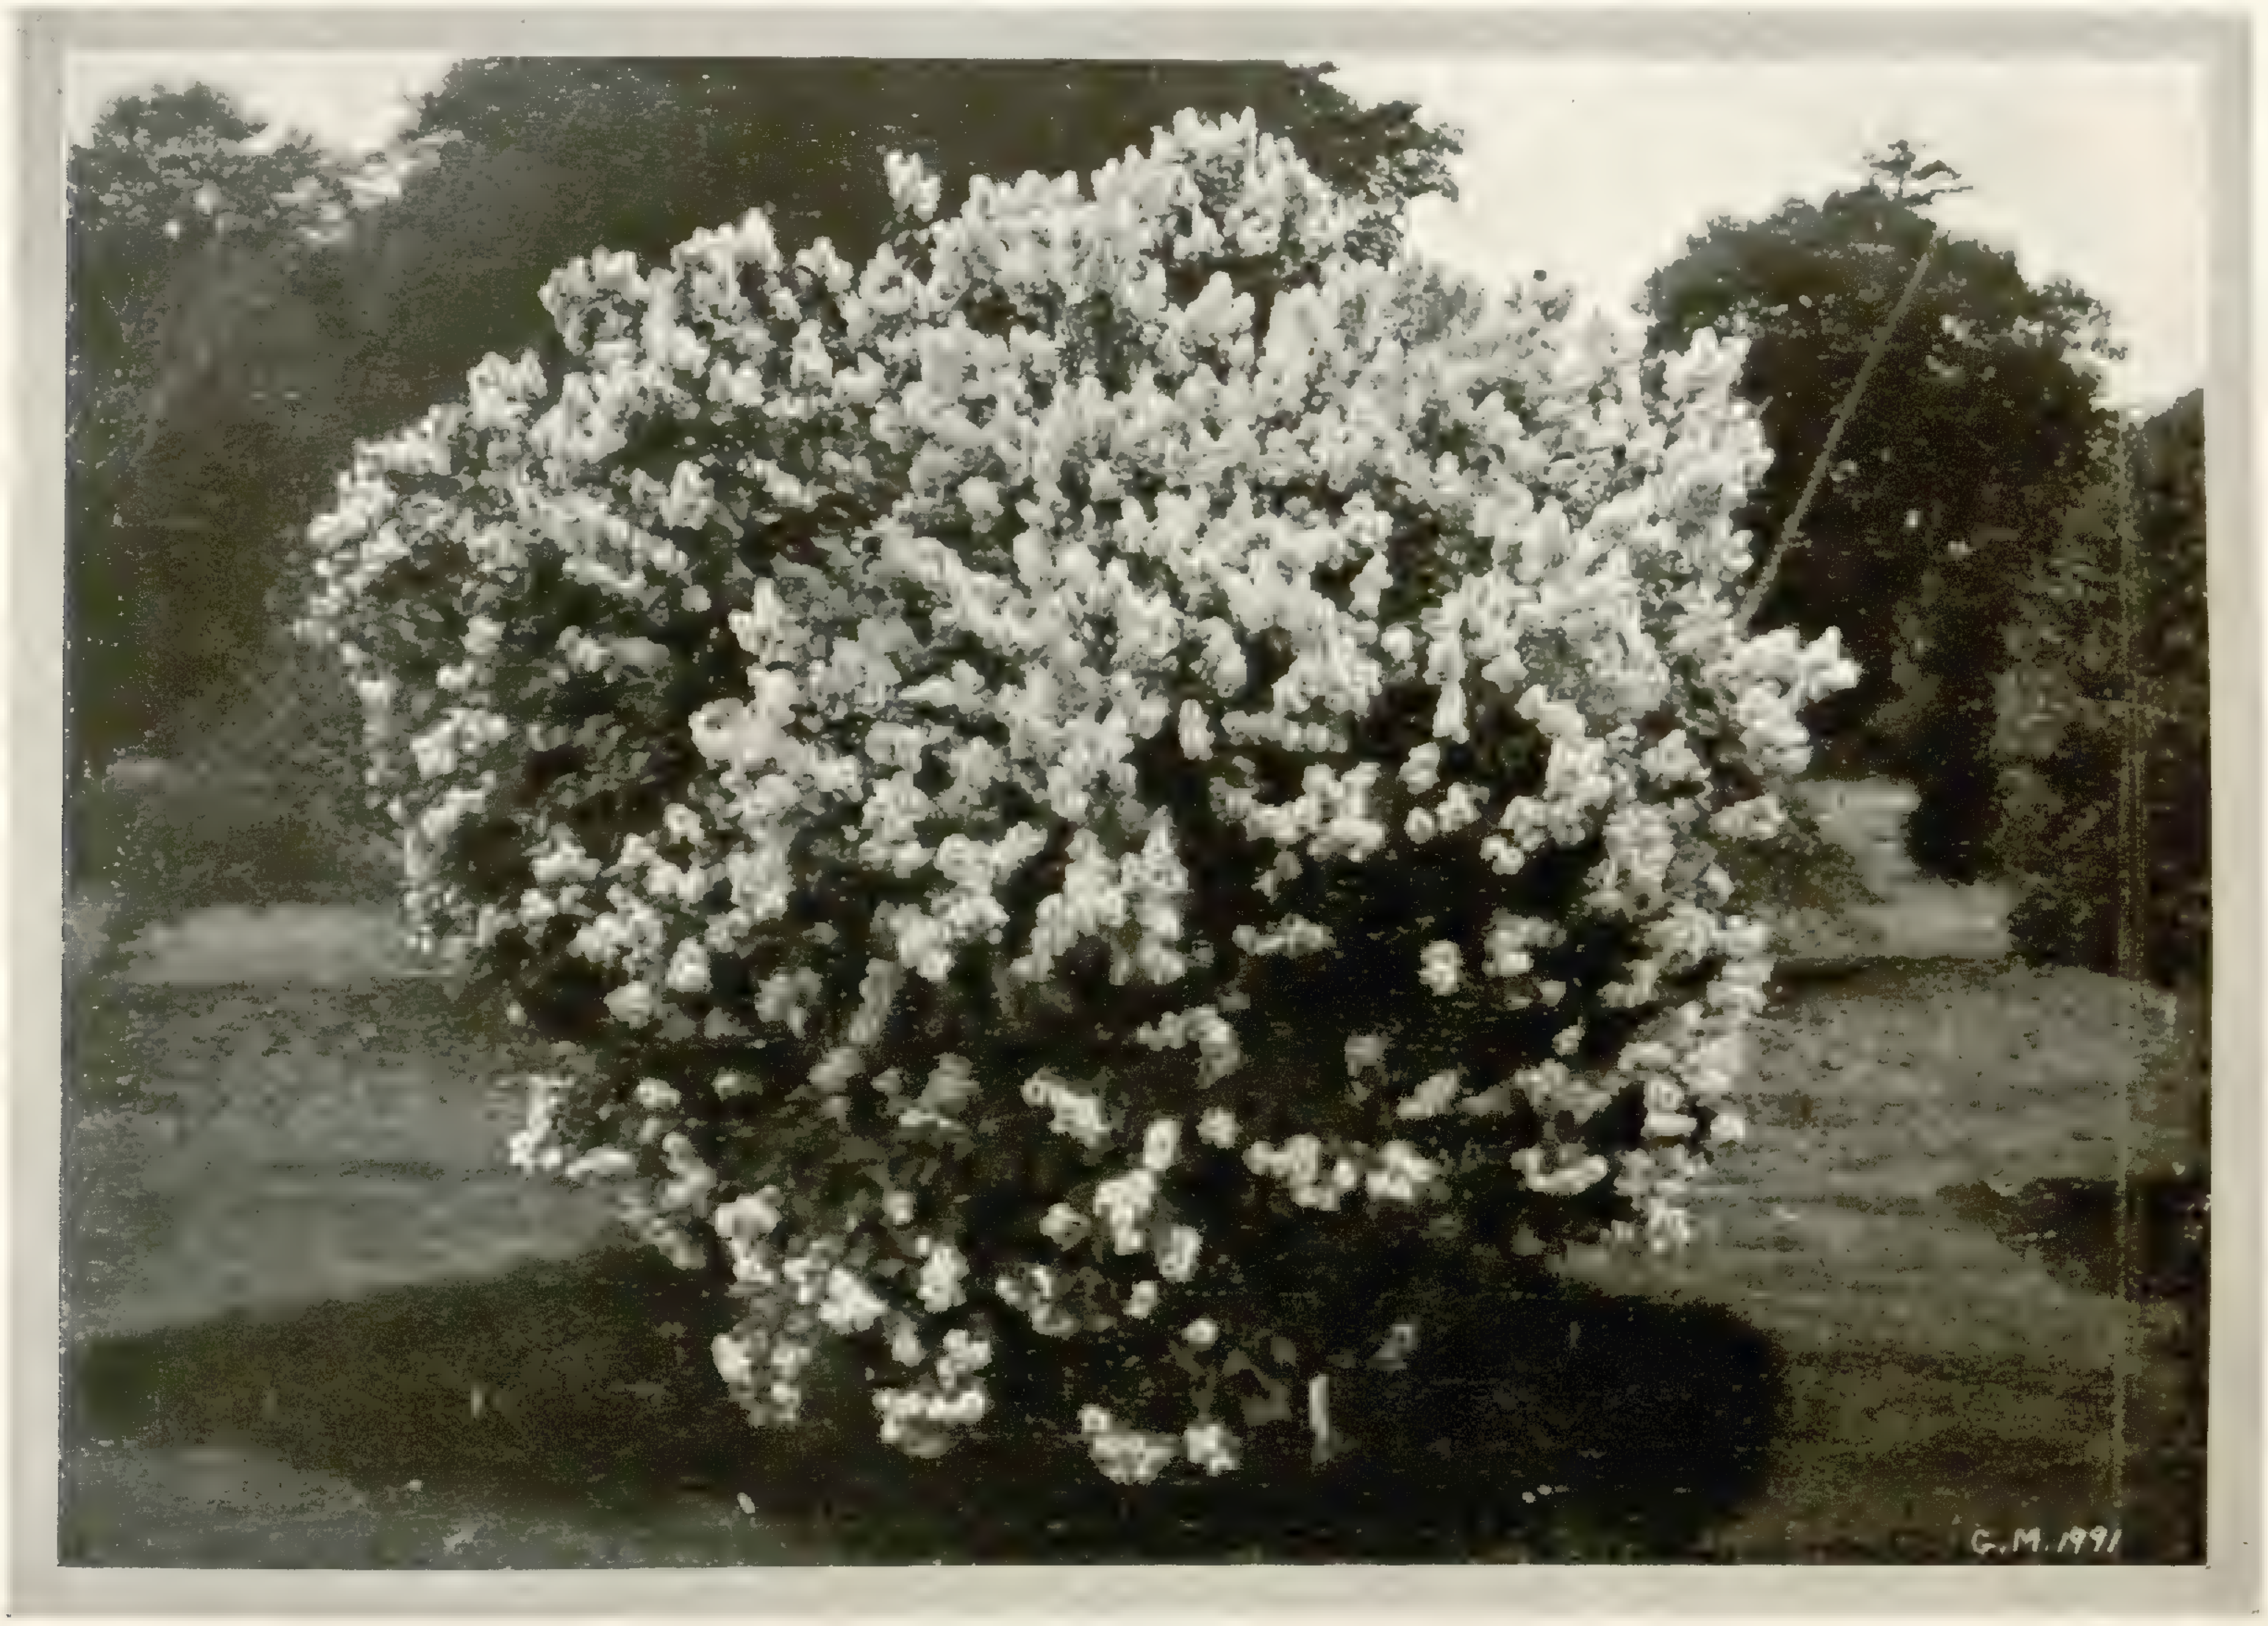
Cratægus pyracantha and C. p. Lelandi are two useful wall shrubs, the latter creating a brilliant picture when in fruit. Among the crabs we have the Siberian, with round, delicately-tinted fruits, and John Downie, with elongated fruits. Berberis Thunbergi has oval coral-red berries borne on the undersides of the shoots; B. vulgaris and B. Wilsonæ are also very showy. Benthamia fragifera (or Cornus capitata) requires the warm climate of the south and south-western counties, for its successful cultivation. The fruits are round and bright red, from whence the tree takes its name of the Strawberry tree. Arbutus Unedo is also sometimes called the Strawberry tree, for it bears bright red fruits in the autumn.

Pernettyas and skimmias are useful dwarf shrubs bearing an abundance of berries. The Snowberry (Symphoricarpus racemosus) is a well-known shrub, with white berries. Euonymus europæus bears an abundance of coral-red berries, which are great favourites with the birds. Cydonia japonica and C. Maulei adapt themselves to the covering of walls, the fruit of the former being round and green, covered with small white spots, and those of the latter are yellow.

E. C. Pooley.

FLOWERING SHRUBS AS LAWN SPECIMENS.

In dealing with a subject of this kind it is necessary to take several things into consideration to ensure success, for not only has the soil to be made suitable for the various subjects, but the situation must also be taken into account. It is no uncommon thing to find tender plants occupying exposed situations, open to the winds from all quarters, and we are then told that "they fail to thrive in this part of the country," whereas, if due attention is paid to shelter, even only a short distance away, the same kind of tree or shrub will often grow luxuriantly. One often meets with surprises when travelling about the country; some rare plant is found in an unlooked-for place, and where one might expect to find a collection of choice subjects nothing is seen but the commonest shrubs.



SYRINGA RUBRA DE MARLEY.

A handsome specimen of this old, but beautiful, lilac at Kew. It is equally remarkable for its good habit and freedom of blooming, the colour of the flowers being bright rose-lilac.

One of the chief considerations, next to suitable soil, is the selection of suitable situations, and in most gardens of any dimensions these can be made by judicious planting. It is not the number of trees that one can plant in a certain amount of space, but their disposition, that gives effect. One good specimen is far more pleasing than half a dozen ill-grown plants; this being so, it is well not to overcrowd in the first instance.

Where shrubs are planted for shelter they should be a sufficient distance away so as not to interfere with the growth of those they are intended to protect. Often a shrub that is hardy when grown in an open place will suffer considerably during a severe winter if it has been grown under the shade of other trees. What should be aimed at is shelter from rough winds without overshadowing. When preparing stations for specimen shrubs and trees, two things are essential: see that the sites are well drained and that a suitable compost is provided. Some like a dry, sunny position, others need shade and shelter: some species thrive best in a peaty soil, while others need soil of a more retentive nature. Many prefer soil free from lime, while others fail to grow satisfactorily unless there is a sufficient quantity of lime. Though some kinds are supposed to grow only in peat I have seen them grow most luxuriantly when planted in a heavy loam bordering on clay that has been free from lime; most of the hardy ericas will grow in such soil, and many of the stronger kinds seem to prefer this to peat, but they do not make good specimens as their growths are liable to split off by snow.

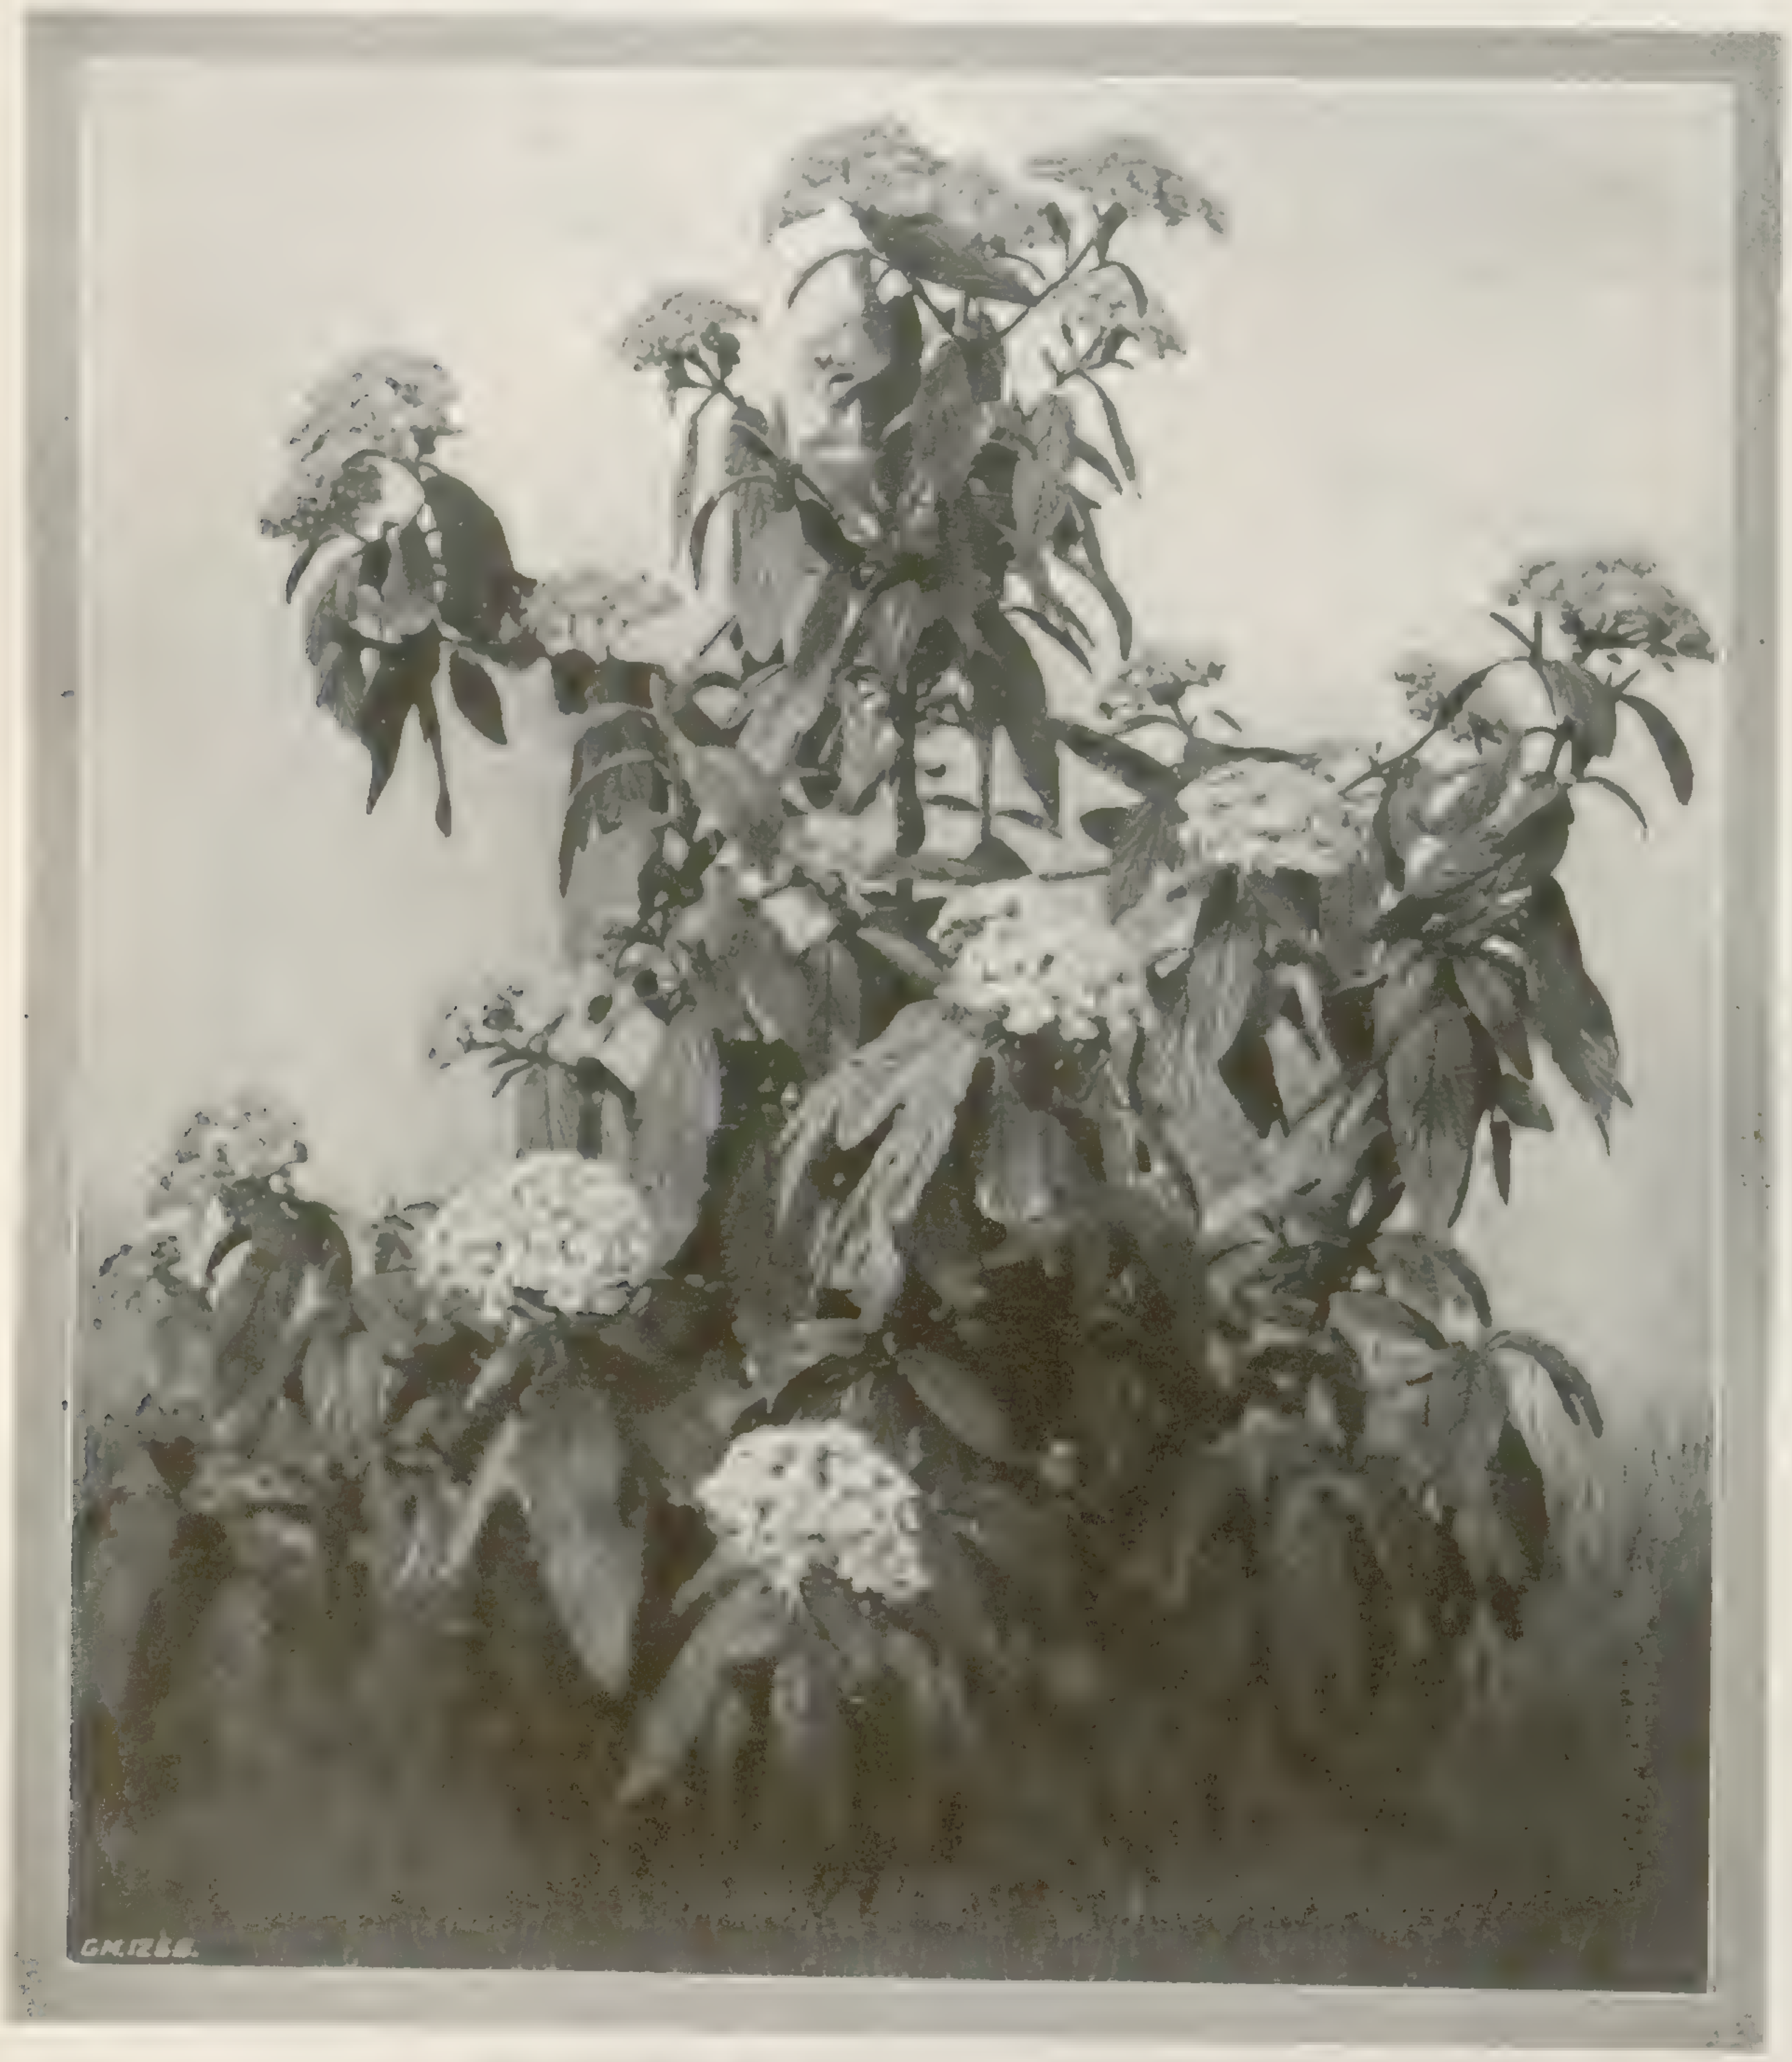
Andromeda japonica and A. japonica variegata make handsome specimens for small gardens, as they are of compact growth and flower most profusely in early spring, and when not in bloom their neat foliage renders them most attractive. A. arborea, too, is a most interesting and charming shrub. Those who have not seen a fine specimen of Enkianthus campanulata in full bloom have a treat in store. This is deciduous, and flowers quite early in spring, having andromeda-like blossoms, but of a dark red colour. It requires the same treatment as the andromedas, and should be grown in the full sunshine. Daphniphyllum glaucescens is an evergreen shrub of compact habit, having large green foliage. It makes a beautiful specimen for the lawn or shrubbery border, especially when it has attained a fair size. Of the many shrubs recently introduced none are more interesting than Viburnum rhytidophyllum. The leaves are from eight to nine inches long, and about two inches broad. The flowers are produced on the points of the shoots during summer, and these are succeeded by dark red berries during the autumn. Of all the virburnums that have been introduced this is without doubt the most interesting, as it retains its foliage and ornamental appearance through the winter. It should be grown in the full sunshine for the fruits to ripen.

Most people know Garrya elliptica as a plant for covering a wall; few, however, have any idea of its beauty when grown as a specimen on the lawn; yet it is only thus that its true character can be seen, as the long catkins then hang down most profusely all round the branches. It requires a deep rich soil and an open situation to ripen the wood, for unless this is properly matured it will not bloom freely. At the same time the plant must not be exposed to cold east or north-east winds. Many of the magnolias make grand specimens for lawns, but these must be planted in sheltered positions, though away from the shade of trees. They thrive best in a light rich loam, but must on no account be allowed to become waterlogged at the roots, or they will suffer severely. Of pittosporums, none, in my opinion, make such neat specimens as P. Mayanum. When allowed plenty of room it makes a fine natural pyramid, flowering on the points of the growths.

Most people are acquainted with Ruscus aculeatus (Butchers' Broom), yet how few know R. racemosus or Alexandrian Laurel. When this is planted in an exposed situation in light rich soil it makes one of the neatest specimens it is possible to imagine. Its long slender shoots are clothed with pale green glossy leaves, at the axils of which are produced small racemes of white flowers; these are succeeded in the autumn by clusters of red berries, which render the plant most attractive throughout the winter. Not only is this plant useful as a specimen for a bold place on the rock garden, but its shoots are well adapted for cutting, as they retain their freshness for suitable for forming an almost impenetrable wall of greenery, that will withstand storm and strees, and prove an object of grace and beauty for several centuries.

The Yew.

This is of slow growth, a point which, in some respects, constitutes its chief merit, for, as already stated, a hedge once formed, of sufficient height and breadth for its purpose, can, by the means of an annual trimming, be kept to a regulation shape and size for a very long period. When preparing a site for planting a trench fully three feet in width and two feet or more in depth, breaking up the lower strata deeply before returning the excavated soil is required. If poor in quality dung or leaf-soil may be mixed throughout to a moderate extent, and, what is still more important, a fair amount of lime to soils deficient in this commodity must be added. The yew will thrive in most soils and positions, and withstands shade from overhanging trees or contiguous buildings better than any other evergreen. The plants, at the time of insertion, should be about two feet in height, and have been transplanted yearly to encourage the formation of small fibrous roots. Pruning, with the exception of the removal of a rampant shoot here and there, will not be required for at least two years from time of planting. It is best done in the spring months, and watering should be well attended to for the season thereafter. Before pruning proper is set about consideration should be given to the situation, and a decision arrived at as to the contour of the future hedge. To harmonise with an ancient mansion or its appurtenances straight perpendicular sides, with flat top, is probably the best. As a first step towards this, with sharp shears clip both sides evenly, and reduce the top growth in moderation, the standard of size being set by the weakest part, if such there be. Where two clippings can be given each year the latter parts of June and August are most fitting, but, if only one, the latter period is preferable, the growths then being matured.



VIBURNUM RHYTIDOPHYLLUM.

A distinct evergreen shrub, with handsome foliage, and bearing, at the points of the growths, corymbs of yellow-white flowers, which are succeeded by deep red berries.

The Holly.

This is an excellent plant for hedges, more especially where such are wanted for ornament and shelter, rather than utility. The spinous foliage is, in this respect, of some assistance in resisting the onsets of cattle or other would-be intruders, but several years must necessarily elapse after planting ere the branches attain sufficient rigidity to be thoroughly effective in this way, while anyone having had much experience with holly knows the difficulty that ensues when a gap becomes a reality. The some preparation of site as detailed for the yew holds good, but if the soil is not fairly rich, liberal additions of manure or good loam should be added, and any depression of surface in the line, whereby water might accumulate to the detriment of the plants must be drained. A rich, warm, and moderately dry soil is most suitable. As an aid to this, upon shallow soils or very moist situations, the digging of a small trench or ditch alongside the prospective line of fence, laying the soil thus excavated in such a way that a bank, from one to two feet in height, is formed, into which, when well consolidated, the roots of the plants may be inserted, is of great assistance. An oval-shaped hedge is preferable for the holly, and severe pruning should be deferred for a considerable time to enable the roots to obtain a good grip of the soil.

JAMES DAY.

ORNAMENTAL FRUITING TREES AND SHRUBS.

Now that the planting season is near at hand, the value of ornamental fruiting trees and shrubs must not be overlooked. A tree or shrub may be beautiful when in flower or again in the autumn, with its changing tints of foliage, yet the brilliant fruits and berries are, in many cases, not taken into consideration. In many instances, aucubas are planted for their foliage alone, yet if a few male plants are mixed with them, a glorious crop of berries will result. The same method must be adopted with the sea buckthorn, i.e., a few male plants must be planted to provide pollen.

The Mountain Ash (Pyrus aucuparia) is familiar to everyone, with its large bunches of scarlet berries, and the various hollies are too well known to need mention here. The common Dog rose (Rosa canina) makes a bright picture in the hedgerow, and some corner in the wild garden should be found to accommodate it on account of its fruits. R. rugosa has fine hips, and it is an excellent species for grouping in the shrubbery. The cotoneasters should be largely planted, on account of their free berry bearing propensities; C. frigida is the tallest growing, and deserves to be more popular than it is at present. It carries large, flat heads of bright scarlet berries, and is a striking object in the autumn. Others worthy of mention are C. horizontalis, C. rugosa Henryi, C. microphylla, C. Simonsi, C. pannosa, and C. applanata. Viburnum rhytidophyllum is highly attractive, with its foliage and berries, the latter being borne in flat bunches at the extremities of the shoots. V. Henryi and V. phlebotrichum are also good. The peculiar racemes of fruit of Leycesteria formosa makes it an interesting shrub.

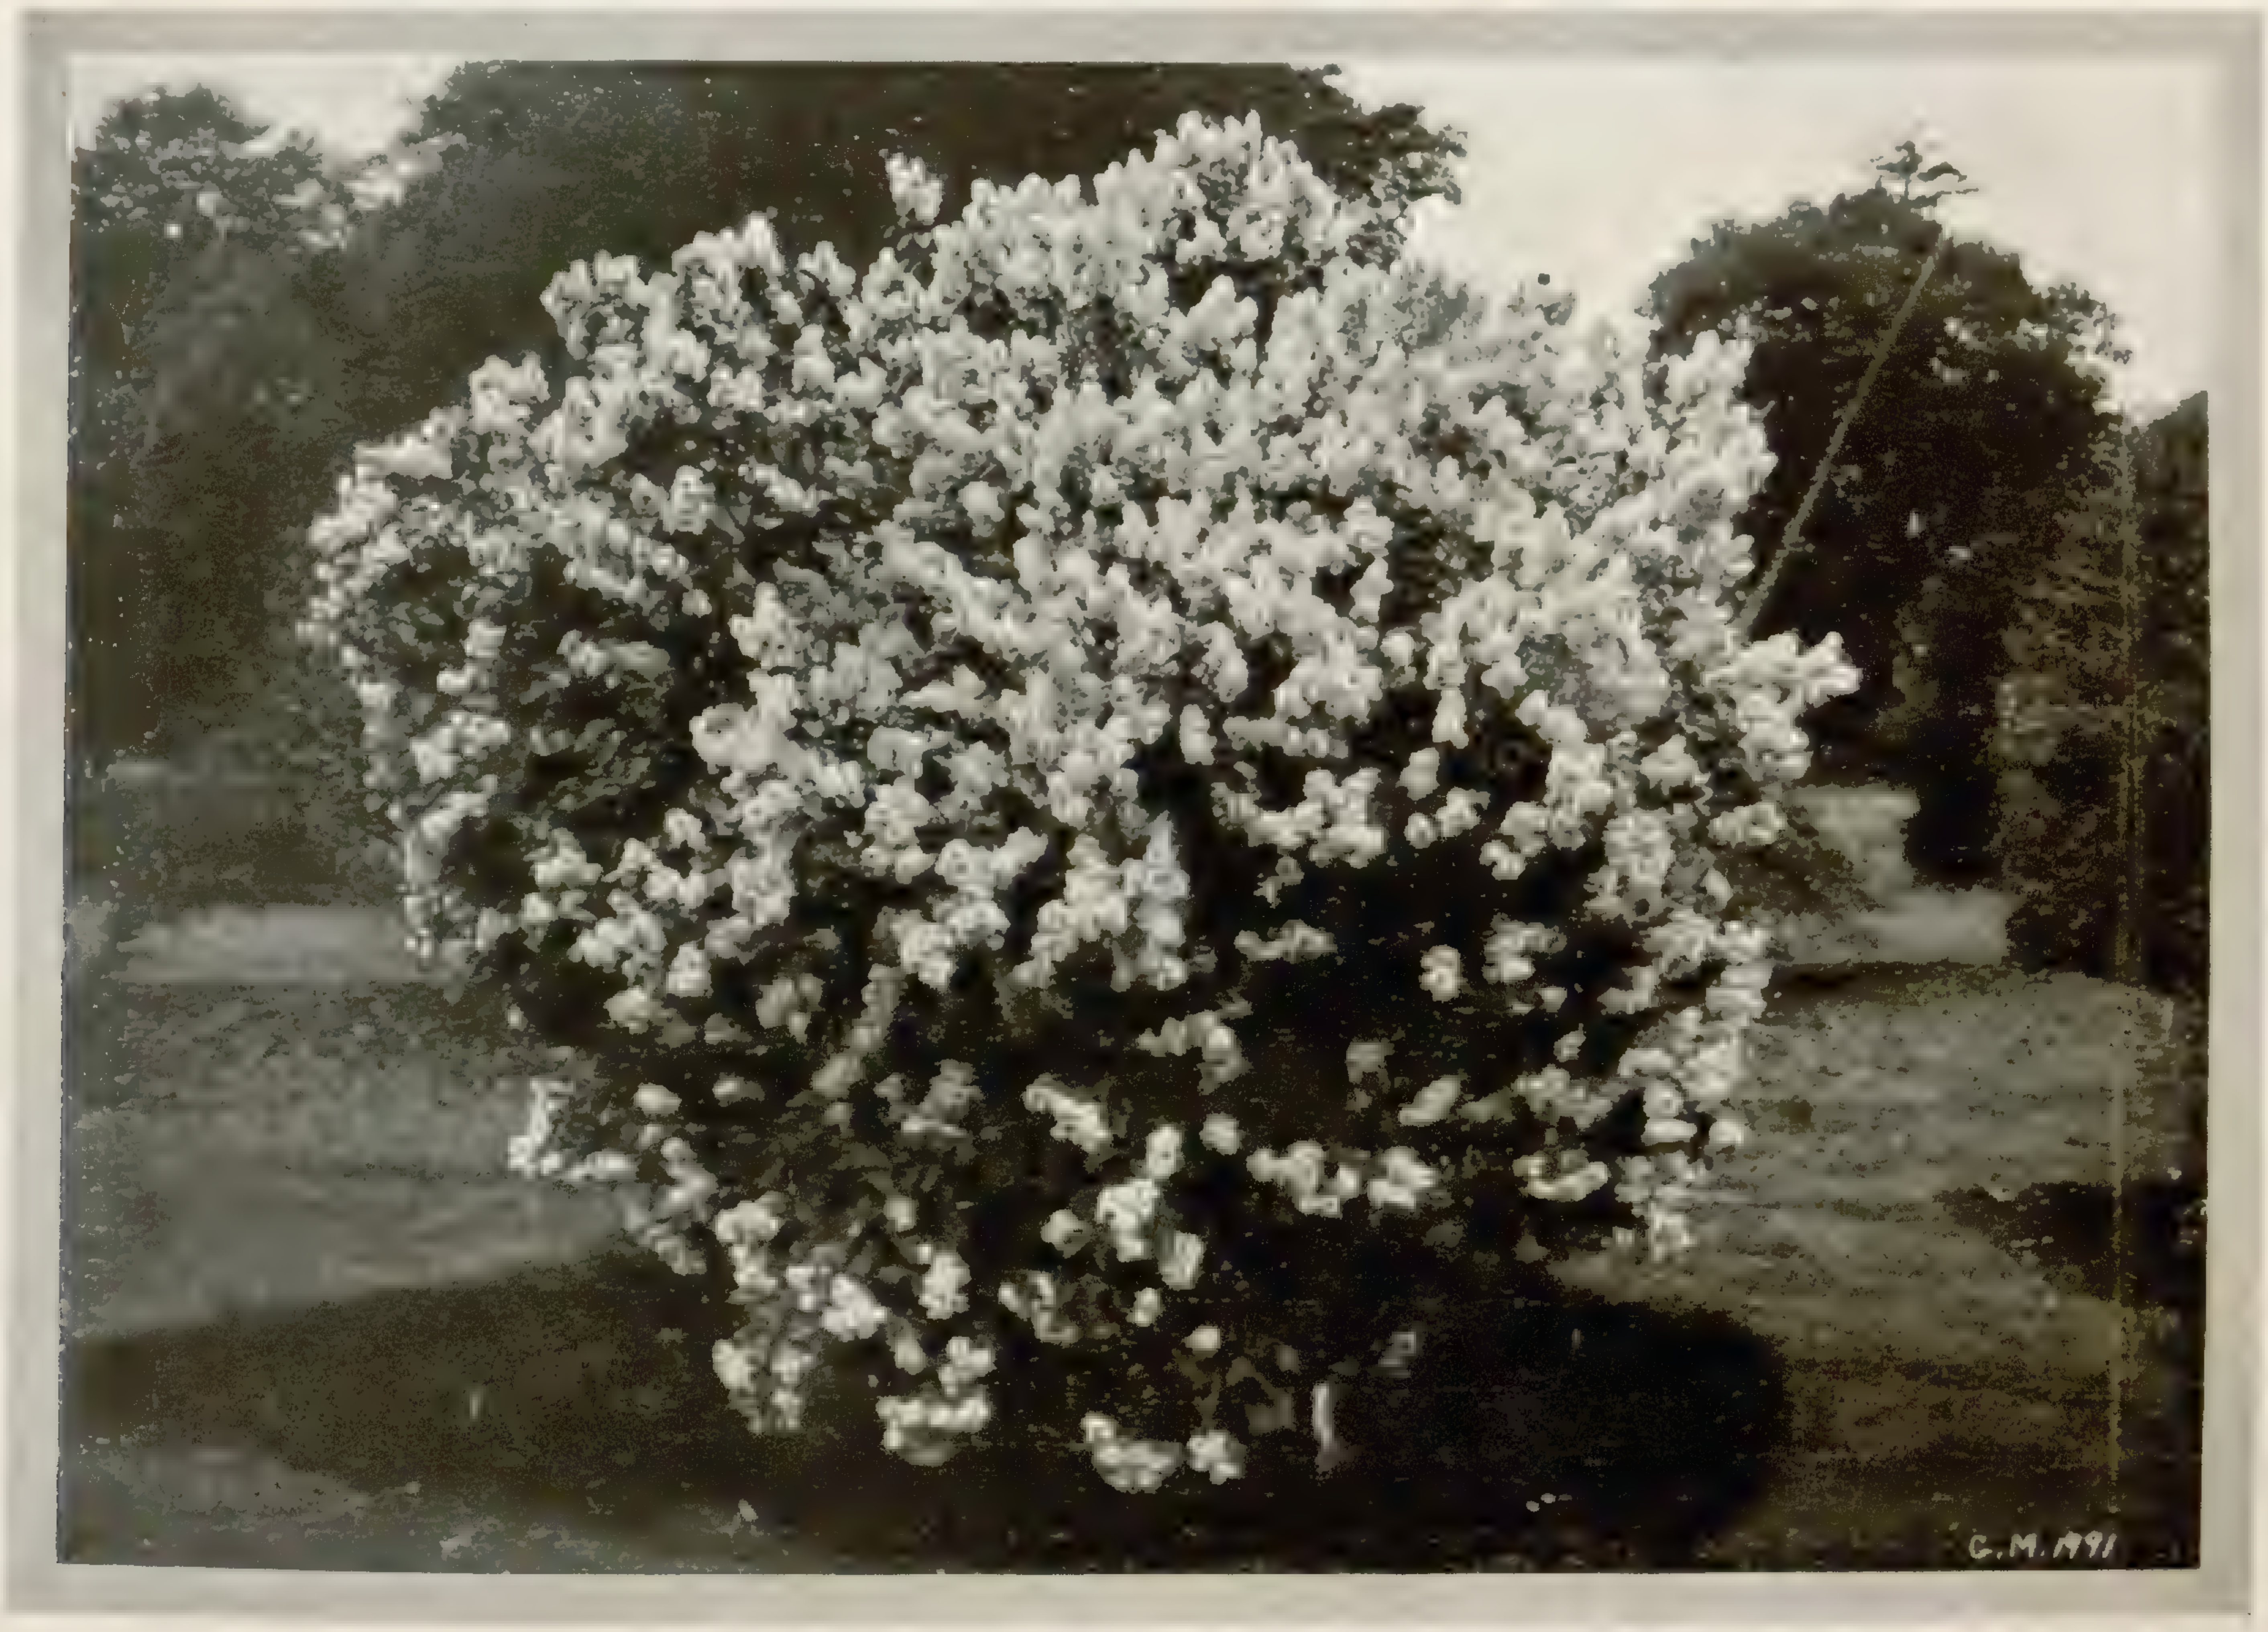
Cratægus pyracantha and C. p. Lelandi are two useful wall shrubs, the latter creating a brilliant picture when in fruit. Among the crabs we have the Siberian, with round, delicately-tinted fruits, and John Downie, with elongated fruits. Berberis Thunbergi has oval coral-red berries borne on the undersides of the shoots; B. vulgaris and B. Wilsonæ are also very showy. Benthamia fragifera (or Cornus capitata) requires the warm climate of the south and south-western counties, for its successful cultivation. The fruits are round and bright red, from whence the tree takes its name of the Strawberry tree. Arbutus Unedo is also sometimes called the Strawberry tree, for it bears bright red fruits in the autumn.

Pernettyas and skimmias are useful dwarf shrubs bearing an abundance of berries. The Snowberry (Symphoricarpus racemosus) is a well-known shrub, with white berries. Euonymus europæus bears an abundance of coral-red berries, which are great favourites with the birds. Cydonia japonica and C. Maulei adapt themselves to the covering of walls, the fruit of the former being round and green, covered with small white spots, and those of the latter are yellow.

E. C. POOLEY.

FLOWERING SHRUBS AS LAWN SPECIMENS.

In dealing with a subject of this kind it is necessary to take several things into consideration to ensure success, for not only has the soil to be made suitable for the various subjects, but the situation must also be taken into account. It is no uncommon thing to find tender plants occupying exposed situations, open to the winds from all quarters, and we are then told that "they fail to thrive in this part of the country," whereas, if due attention is paid to shelter, even only a short distance away, the same kind of tree or shrub will often grow luxuriantly. One often meets with surprises when travelling about the country; some rare plant is found in an unlooked-for place, and where one might expect to find a collection of choice subjects nothing is seen but the commonest shrubs.



SYRINGA RUBRA DE MARLEY.
A handsome specimen of this old, but beautiful, lilac at Kew. It is equally remarkable for its good habit and freedom of blooming, the colour of the flowers being bright rose-lilac.

One of the chief considerations, next to suitable soil, is the selection of suitable situations, and in most gardens of any dimensions these can be made by judicious planting. It is not the number of trees that one can plant in a certain amount of space, but their disposition, that gives effect. One good specimen is far more pleasing than half a dozen ill-grown plants; this being so, it is well not to overcrowd in the first instance.

Where shrubs are planted for shelter they should be a sufficient distance away so as not to interfere with the growth of those they are intended to protect. Often a shrub that is hardy when grown in an open place will suffer considerably during a severe winter if it has been grown under the shade of other trees. What should be aimed at is shelter from rough winds without overshadowing. When preparing stations for specimen shrubs and trees, two things are essential: see that the sites are well drained and that a suitable compost is provided. Some like a dry, sunny position, others need shade and shelter; some species thrive best in a peaty soil, while others need soil of a more retentive nature. Many prefer soil free from lime, while others fail to grow satisfactorily unless there is a sufficient quantity of lime. Though some kinds are supposed to grow only in peat I have seen them grow most luxuriantly when planted in a heavy loam bordering on clay that has been free from lime; most of the hardy ericas will grow in such soil, and many of the stronger kinds seem to prefer this to peat, but they do not make good specimens as their growths are liable to split off by snow.

Andromeda japonica and A. japonica variegata make handsome specimens for small gardens, as they are of compact growth and flower most profusely in early spring, and when not in bloom their neat foliage renders them most attractive. A. arborea, too, is a most interesting and charming shrub. Those who have not seen a fine specimen of Enkianthus campanulata in full bloom have a treat in store. This is deciduous, and flowers quite early in spring, having andromeda-like blossoms, but of a dark red colour. It requires the same treatment as the andromedas, and should be grown in the full sunshine. Daphniphyllum glaucescens is an evergreen shrub of compact habit, having large green foliage. It makes a beautiful specimen for the lawn or shrubbery border, especially when it has attained a fair size. Of the many shrubs recently introduced none are more interesting than Viburnum rhytidophyllum. The leaves are from eight to nine inches long, and about two inches broad. The flowers are produced on the points of the shoots during summer, and these are succeeded by dark red berries during the autumn. Of all the virburnums that have been introduced this is without doubt the most interesting, as it retains its foliage and ornamental appearance through the winter. It should be grown in the full sunshine for the fruits to ripen.

Most people know Garrya elliptica as a plant for covering a wall; few, however, have any idea of its beauty when grown as a specimen on the lawn; yet it is only thus that its true character can be seen, as the long catkins then hang down most profusely all round the branches. It requires a deep rich soil and an open situation to ripen the wood, for unless this is properly matured it will not bloom freely. At the same time the plant must not be exposed to cold east or north-east winds. Many of the magnolias make grand specimens for lawns, but these must be planted in sheltered positions, though away from the shade of trees. They thrive best in a light rich loam, but must on no account be allowed to become waterlogged at the roots, or they will suffer severely. Of pittosporums, none, in my opinion, make such neat specimens as P. Mayanum. When allowed plenty of room it makes a fine natural pyramid, flowering on the points of the growths.

Most people are acquainted with Ruscus aculeatus (Butchers' Broom), yet how few know R. racemosus or Alexandrian Laurel. When this is planted in an exposed situation in light rich soil it makes one of the neatest specimens it is possible to imagine. Its long slender shoots are clothed with pale green glossy leaves, at the axils of which are produced small racemes of white flowers; these are succeeded in the autumn by clusters of red berries, which render the plant most attractive throughout the winter. Not only is this plant useful as a specimen for a bold place on the rock garden, but its shoots are well adapted for cutting, as they retain their freshness for a considerable time in water. Skimmias, too, are very beautiful, not only on account of their glossy foliage, which they retain through the winter, but for their freedom in flowering and the brightness of their berries through the dull season. They form neat specimens, and, if planted in a mixture of peat, leaf-soil, and loam, will grow freely.

There are many other evergreen shrubs that are most beautiful, but space forbids mention of others here. Turning to those of a deciduous nature, there are many that are not generally found in our gardens, and it would be well if more interest were taken in planting them. I planted a specimen Cæsalpinia japonica some years ago. In appearance it somewhat resembles the old thorny acacia, but does not grow to such a large size. The flowers are of a bright canary yellow, borne on long racemes. The tree when grown on a stem makes a grand specimen for a lawn. Eucryphia pinnatifolia is a most interesting shrub, with foliage somewhat like that of the rose, and flowers, which are pure white, from two to three inches in diameter, and very like those of a hypericum. This is one of the few shrubs that flower at the end of the summer, and on that account it is valuable. It should be planted in an open situation, but, given shelter from the north and north-east winds. Styrax japonicum is of recent introduction, of very pleasing habit, blooms most profusely in the early summer months, when its fragrant, white flowers render it most attractive. I have never seen a large plant of this, as those I planted have not yet attained full growth, but from what I have seen of its character, I should say it would make a most interesting specimen.

There are many of the crabs that make grand specimens for the lawn, shrubbery, or woodland, but none is more pleasing when in bloom than Pyrus floribundus atrosanguinea, its long slender shoots being clothed with brightly-coloured flowers in early spring, these lasting for a considerable time in perfection should the weather be favourable. To be seen at their best the flowering crabs should be planted singly, and be grafted on stems from eight to ten feet high, when their long slender shoots will hang gracefully down, forming garlands of delicate flowers. When in bud, before the flowers expand, the above-named is most attractive. When planting such trees care should be taken not to have three or four bearing somewhat similarly coloured flowers and blooming at the same time in close proximity to each other, otherwise one will spoil the effect of the other. Many of the lilacs make fine lawn specimens under good cultivation, as shown by the specimen of Rubra de Marley illustrated herewith.

H. C. Prinsep.

THE MANNA OR FLOWERING ASH (FRAXINUS ORNUS).
A good specimen of this handsome tree in the Royal Gardens, Kew.

ORNAMENTAL TREES FOR SMALL GARDENS.

The selection of trees for beautifying gardens, whatever may be their area, requires considerable care; but in no case is this so essential as when they are intended for gardens of comparatively small size. In the planting of gardens with widely extending pleasure grounds it is possible to select from a wide range of subjects, because the dimensions to which the larger-growing trees attain when fully developed are not a matter of prime importance. If the planter is wise he will not use otherwise than sparingly trees that properly belong to the park and woodland in the creation of the arborescent features of gardens of large size. But for gardens of moderate area trees that assume large proportions, such as the common horse chestnut, the elms, and the planes, are quite unsuitable, and the planter has accordingly a limitation placed upon the exercise of his taste.

There is no dearth of beautiful trees of moderate growth, and the object of these brief notes is to direct attention to a few that are especially deserving the attention of the owners of gardens with somewhat limited dimensions.

Acers.

The acers include a considerable number of trees of much value for the purpose in view, prominent among them being those of Japanese origin. Grown as round-headed standards, on stems five or six feet in height, Acer palmatum and its varieties are very attractive, whether planted in prominent positions on the lawn or in the shrubbery border. The specific form has elegant green leaves; A. palmatum palmatifidum has leaves that are finely cut; A. palmatum purpureum is remarkable for its deep bronze-purple leaves; A. palmatum flavescens has leaves of a yellow-green hue, and is useful as a contrast to the dark-leaved forms.

The varieties of A. negundo claim attention for their distinctive colouring, and the facility with which they can be kept to a quite small size should it be necessary. A. negundo californica aurea is rich in colour, and one of the most effective of the golden-leaved trees of small growth. A negundo aurea elegantisima is vigorous in growth, and the leaves have a bright yellow margin, and A. negundo albo marginatum is the most effective of hardy deciduous trees with silvery variegation.

Æsculus.

While the horse chestnut, notwithstanding its nobility of aspect and attractiveness during its season of flowering, should be excluded from the garden of moderate size, the Red-flowered Chestnut (Æ. carnea) should have a place therein, provided a sunny position can be given it, for it is compact in growth, of handsome contour, and attractive when in bloom. The variety known as Brioti has flowers of a deeper colour, and is most desirable. Æ. flava and Æ. macrostachya, also known as Pavias, are handsome small trees that produce handsome spikes of yellow flowers in summer.

Birches.

The birches are extremely beautiful when they have room for their full development, but they are now referred to for the purpose of directing attention to the elegant weeping form of Betula alba known as Youngi. This is one of the most graceful of all the weeping trees, and as comparatively little space is required for a specimen, it may be described as the best weeping deciduous tree for the small garden.

Cherries.

The ornamental cherries include several double forms of great beauty, and as they are all of moderate stature they can be strongly recommended. The following are of exceptional value: Cerasus avium fl. pl., a charming tree, producing a profusion of large double pure white flowers; rather too large for the smallest gardens. C. Rhexi fl. pl., a small-growing round-headed tree, bearing large double white flowers, is very attractive, and suitable for quite small gardens. The two varieties of C. pseudo-cerasus, known as Watereri and J. H. Veitch are of great beauty, and should have a place in all gardens. They have large double flowers, those of the last-named being the largest, and the colour is pale pink and rich pink respectively. J. H. Veitch is the best of the two, and if they bloomed simultaneously it should alone be grown, but as it is a fortnight later in flowering they are both required. C. Mahaleb pendula is a charming tree, delightful in spring, when enwreathed in its snowy blossoms, and so elegant in habit as to be attractive throughout the season of growth.

Cratægus, or Thorns.

The thorns, of which there are many beautiful species and varieties, deservedly occupy a high position among small trees remarkable for the beauty of their flowers, and should be included in the smallest selection for gardens of moderate size. The varieties of Cratægus oxycantha, known as Paul's Double Scarlet, Double Pink, and Double White, form an invaluable trio. The weeping thorn, which has single white flowers, is remarkable for its elegance; and C. Carrieri and C. tanacetifolia are two handsome white-flowered species that bloom a week or ten days after the varieties of C. oxycantha have flowered, and desirable where space can be found for them.

Fraxinus.

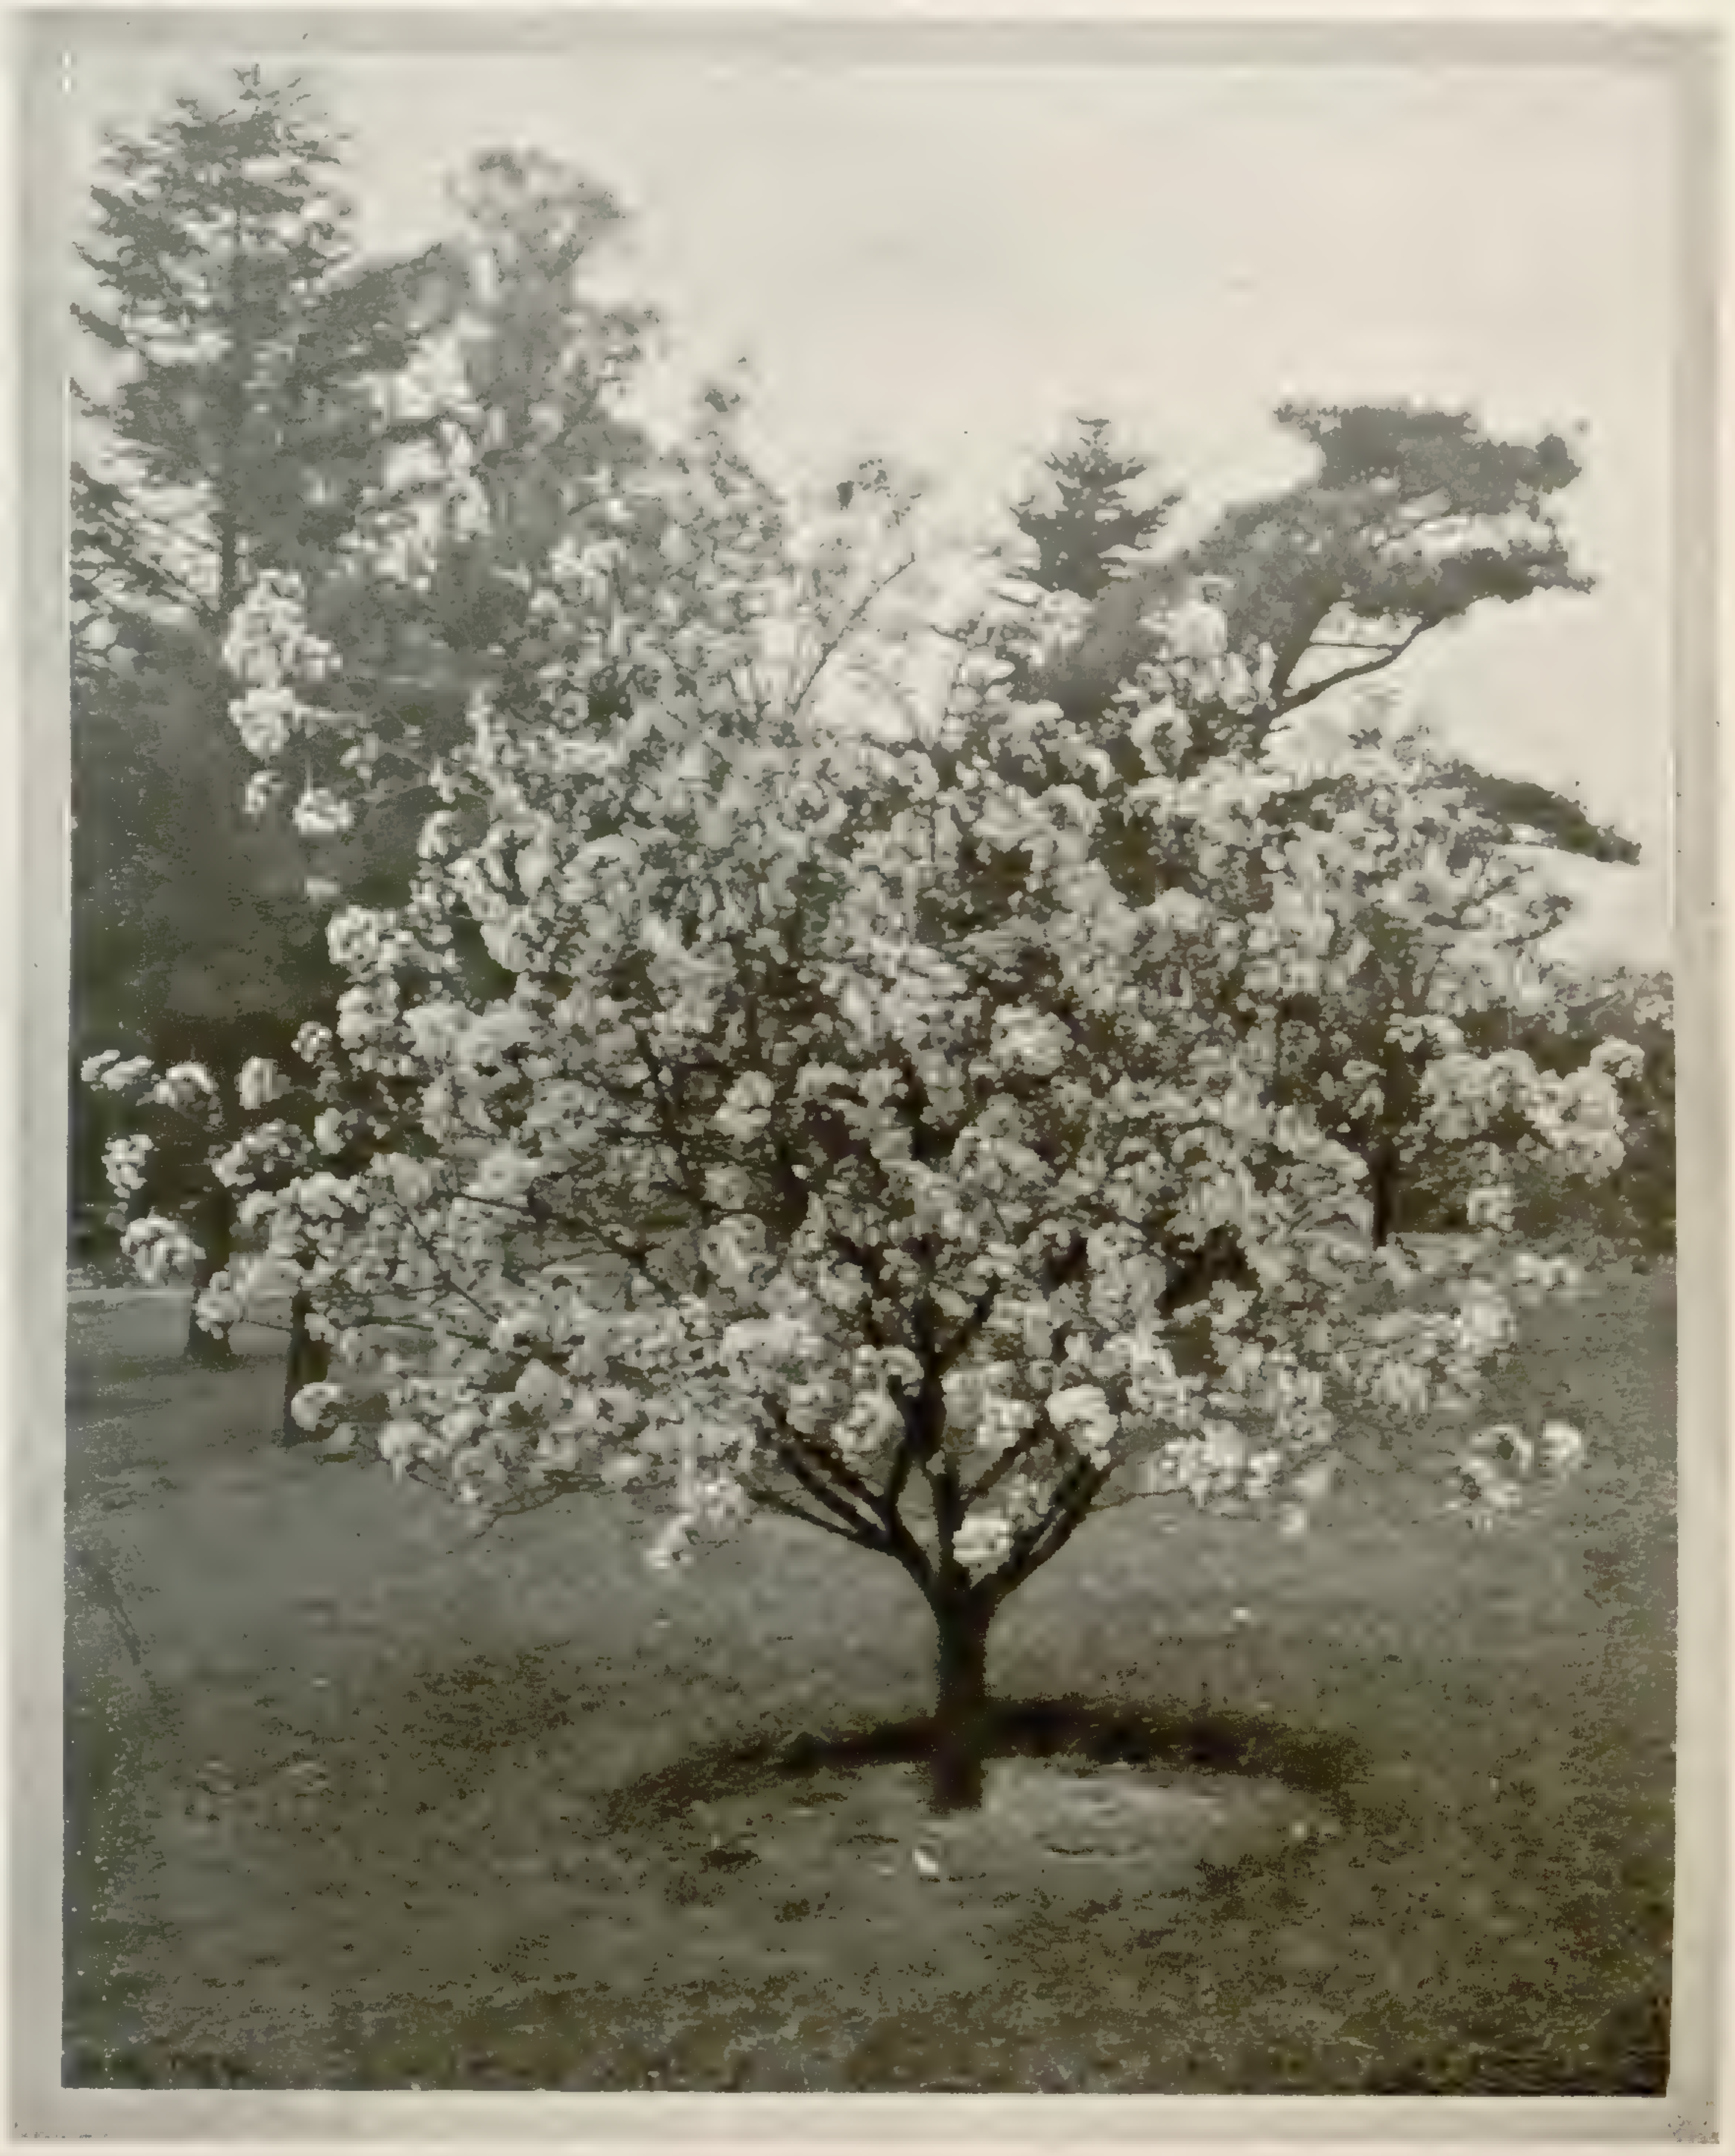
There are a number of varieties of the Common Ash (Fraxinus excelsior) that are distinctly handsome, but they are too large in growth for the present purpose, and they, or, rather, the stock on which they are worked, have long shallow roots, which spread considerable distances from the stem, and rapidly exhaust the soil through which they pass of the food constituents it contains. The Manna, or Flowering Ash (F. ornus) is, on the other hand, of rather moderate stature, and less exhaustive of the soil. The illustration herewith admirably shows the habit of the tree. It has elegant pinnate leaves, which are retained without change of colour until quite the end of October, and bears a profusion of greenish-white flowers in June.

Magnolias.

These comprise some of the most noteworthy of the deciduous trees, and as the most beautiful kinds are of small growth they are especially suited for small gardens. The Yulan (M. conspicua) and M. Soulangeana, are both of the highest value, and should be included in the smallest selection. Alexandrina and nigra are two handsome varieties of the last-named, with relatively large flowers, which are respectively pale pink and deep purple respectively. These magnolias should be given an open position, preferably where they will be sheltered from easterly winds, and be planted in a bed of soil consisting of turfy loam, to which a liberal addition of leaf-mould has been made.

Pyrus.

The ornamental crabs that are chiefly valued for the beauty of their flowers include some of the finest of garden trees, and a small selection should include Pyrus coronaria fl. pl., a distinct form, with large double pink flowers, that are sweetly scented; P. floribunda atrosanguinea, a beautiful variety, with richly-coloured flowers; P. Scheideckeri, a fine hybrid, erect in growth, and free in blooming, the flowers large and blush-pink; and M. spectabilis fl. pl., a handsome tree bearing a profusion of bright pink flowers. G.



A BUSH TREE OF PYRUS SCHEIDECKERI.

A handsome hybrid, bearing large blush-pink flowers.

JACOBINIA CHRYSOSTHEPHANA.

This is one of the most handsome of winter-flowering stove plants, and for decorative purposes in the conservatory or dwelling-house it is especially useful. The bright orange-yellow flowers are freely produced at the apex of the shoots in dense heads, and they will remain perfectly fresh for several weeks, rendering the plants especially valuable. This Jacobinia is not so frequently grown in private gardens as it deserves, but if its merits were more widely known, I feel sure that there would be few gardens of any pretensions where it would not be regularly cultivated, and in many instances it would become a rival to the ever-popular poinsettia.

A stock is readily raised from cuttings during April ; they are inserted singly in thumb pots, and plunged in a propagating case until rooted. They are then put into 60's, and grown on in an intermediate temperature. from these they may be shifted into 32's, in which they are allowed to flower. For the final shift, a compost consisting of two-thirds good fibrous loam and one-third leaf soil, with the addition of a little crushed charcoal and silver sand, suits them admirably. Pot moderately firmly, and grow on in the same structure until the roots are pushing freely into the new soil, when the plants should be removed to a sunny frame, in which they can remain until the end of August.

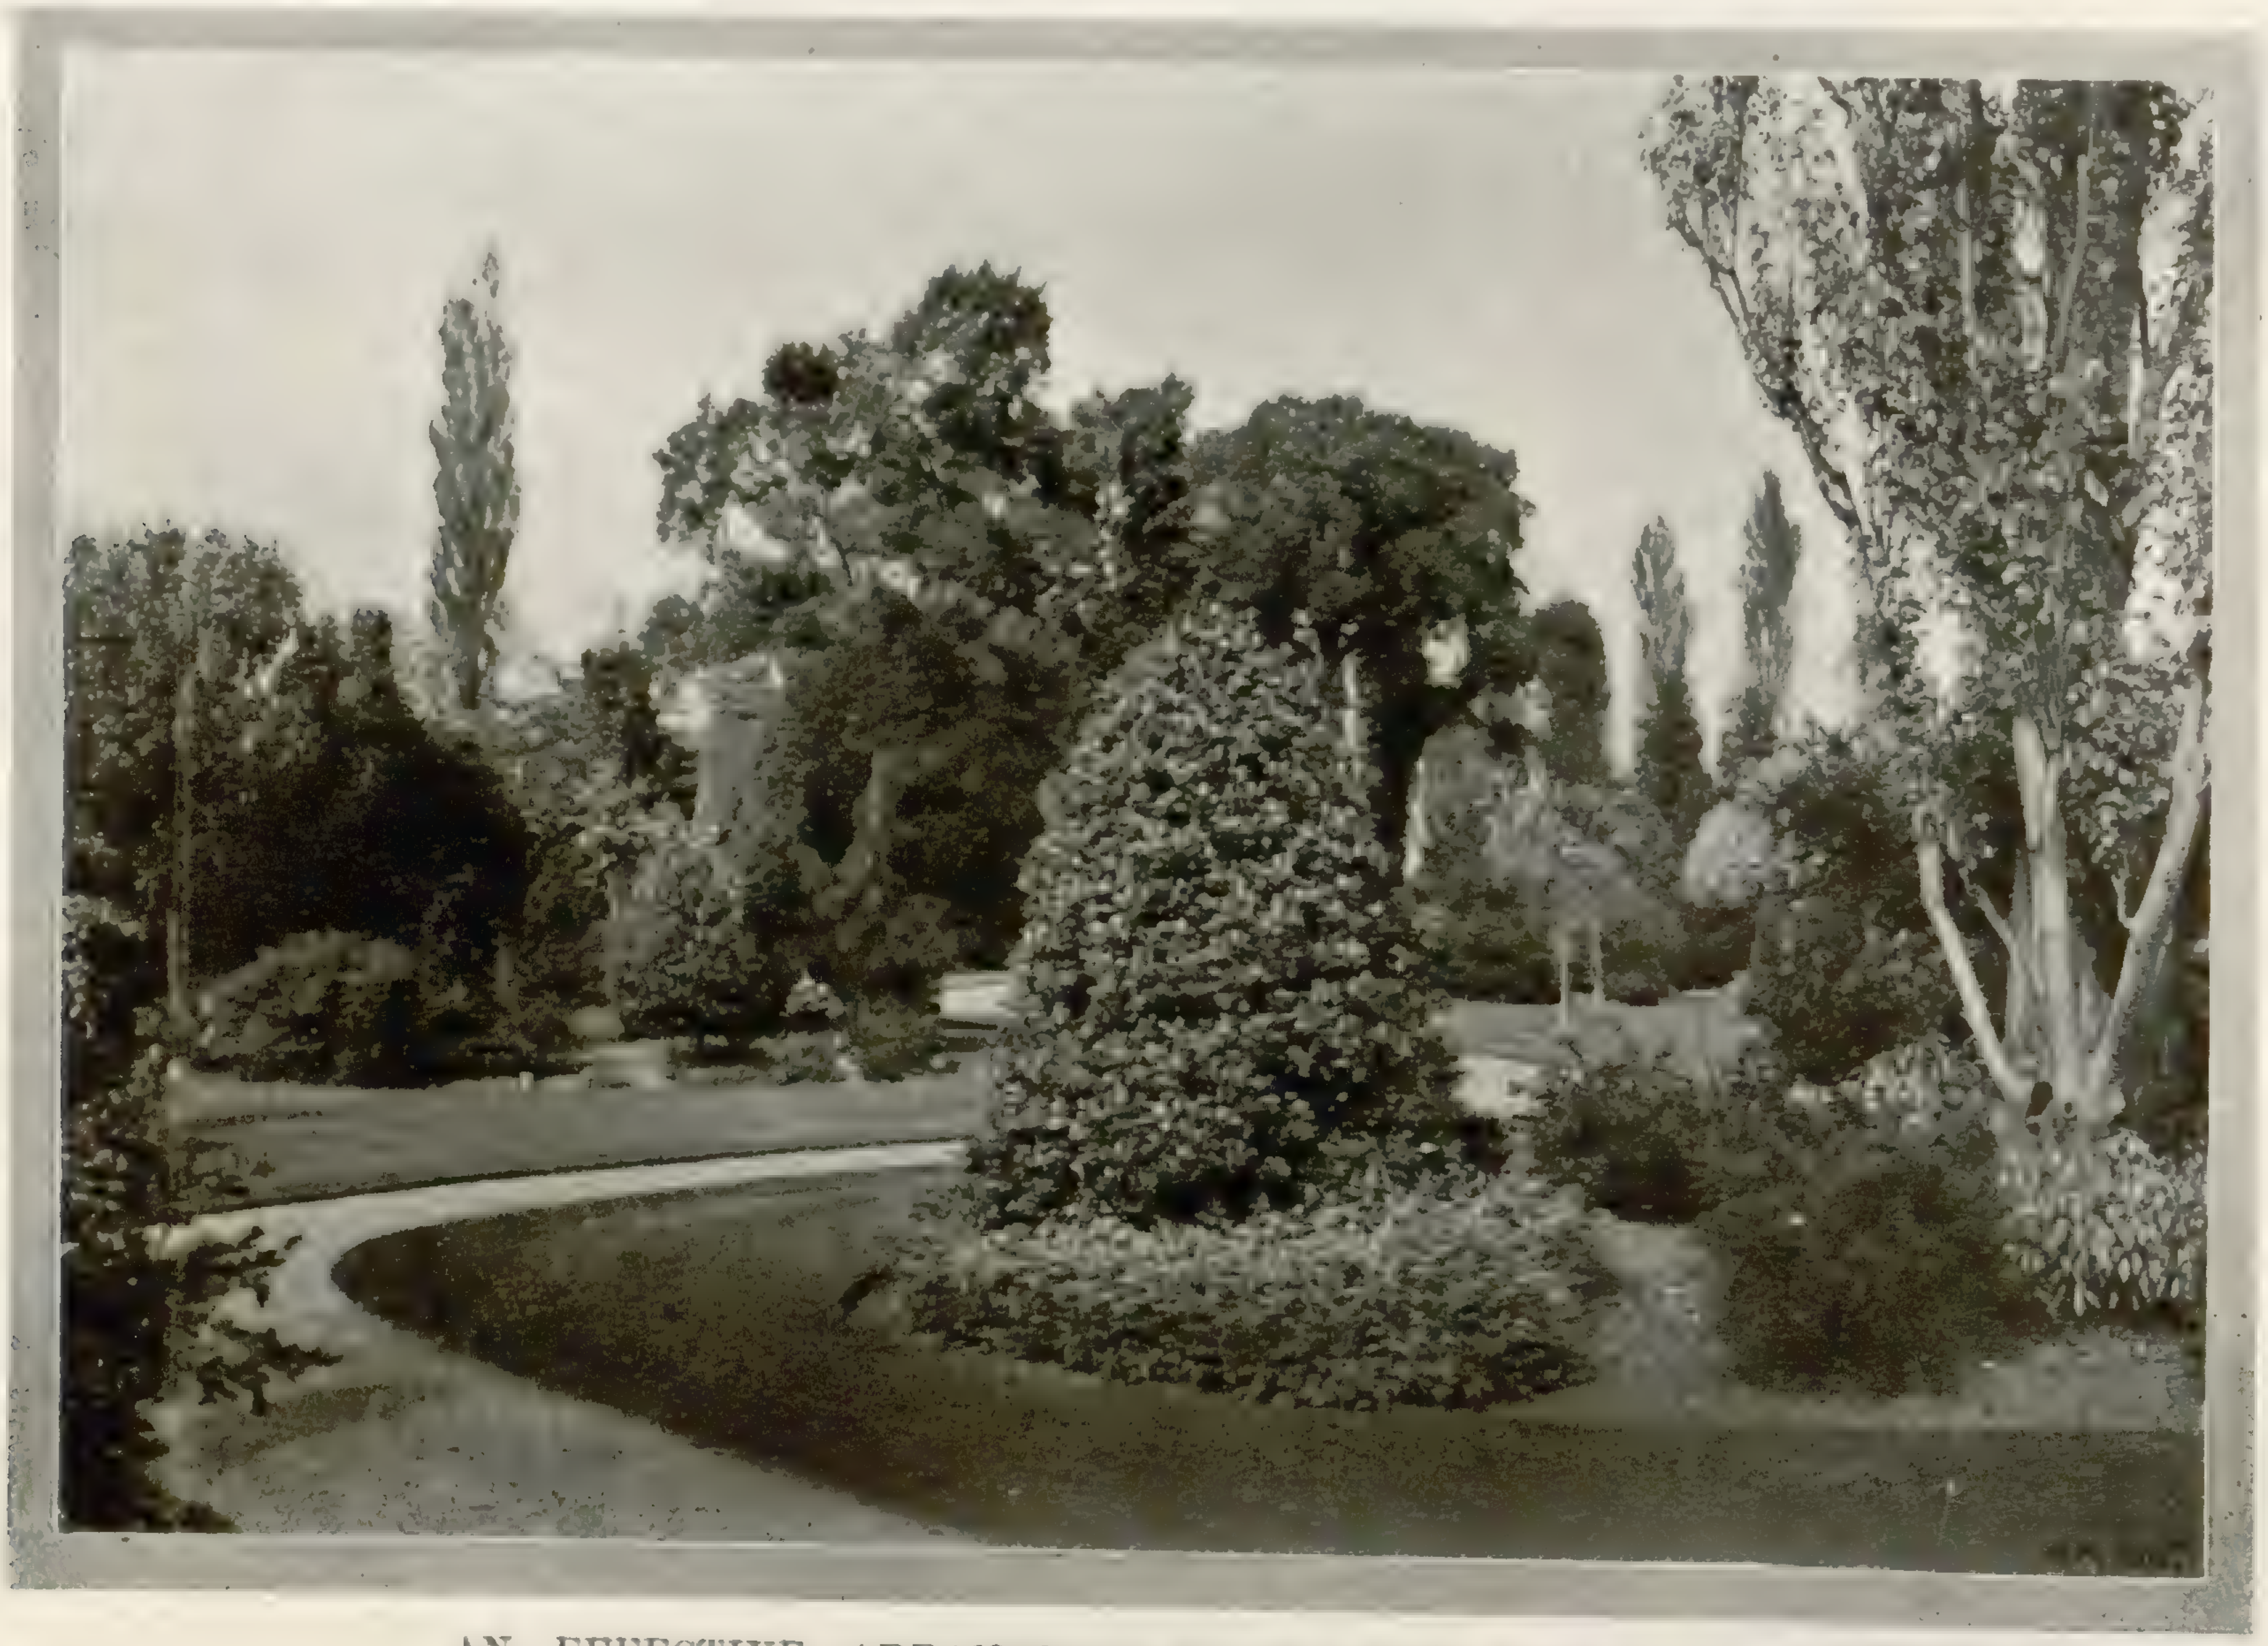
Syringe them regularly during fine weather, and shade lightly from bright sunshine. The points of the shoots should be pinched out after they have formed three pairs of leaves, to induce them to form side growths. When they are housed in the autumn a light house with a temperature of 60 degrees is the most suitable, and during that period they should be exposed to the full influence of the sun to thoroughly mature their growth. Weak soot water is helpful during the growing period, and, as the flower-heads commence to develop, occasional light top-dressings of some approved fertiliser are an assistance. The plants can be cut back and grown on a second year, shifting them into 8in. pots, when they invariably form bushy specimens.

J. Gardner.

BULBS.—A practical treatise on the cultivation of hardy, hothouse and greenhouse bulbous and tuberous rooted plants is "Bulbs and their Cultivation," by T. W. Sanders, price 2s. 6d. net, or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

GROUPING HARDY TREES AND SHRUBS.

Notwithstanding the prodigal number of free-flowering shrubs at present available for garden adornment, and having in mind their comparative inexpensiveness that renders them in a sense accessible to all, one cannot but regret the neglect to which they are so often subjected, and, in some districts, their very existence might almost be questioned, in so far as their presence receives any practical expression. Other instances might be cited where tolerably good collections are formed, and not infrequently well grown; but the final result, which, after all, is the crucial test of good planting, is an effort that yields nothing decisive. A vast amount of expense has been incurred, much valuable time and labour expended, and in the end one looks in vain for the expression of a definite idea, such as a well thought-out composition ought to reveal. A selection of trees and shrubs is a far more desirable element in a garden than any collection, however comprehensively formed, grouping them so that they may have scope for individual development when the character is strong enough to assert itself, and alternately, massing the weak elements together, from whence will ultimately issue strength. On the whole, it is this latter element that wants emphasising at the present time, as massed shrubs are a source of perennial delight in gardens, however small. Where the grounds are extensive their presence raises the entire surroundings, so that nothing else can approach them in attractiveness. Simple groups afford the most solid displays, when the subjects composing them are in flower, of which familiar instances readily occur in rhododendrons (deciduous and evergreen), spiræas, philadelphus, syringas, berberis, deutzias, and many others. Groups of these in threes, fives, or larger quantities never fail to reveal the distinctive character of the particular kind, nor can we gainsay the sumptuousness of the floral feast produced, as the effect is one we readily appreciate and often eagerly anticipate in future years. Simple groups lend themselves to greatest effect on steep or undulating ground, or along the margins of woodland, where the forest subjects, by their presence, lend assistance in affording the necessary height to redeem this form of planting from the charge of being too flat.



AN EFFECTIVE ARRANGEMENT OF TREES AND SHRUBS
In the gardens of Aldenham House, the residence of the Hon. Vicary Gibbs.

Under other circumstances, composite planting is to be commended, as, by this means we may reproduce perfect landscapes in the smallest space, or form them on any extended scale. In this system of grouping the commonest shrubs have an interest and beauty not readily attained elsewhere. Berberis Thunbergi intergrouped with Cornus elegantissima, and a few of Corylus avellana purpurea or Berberis vulgaris purpurea planted through them presents a harmonious colour group, becoming radiant in autumn, when Thunbergi foliage takes on the ripening colours in the leaves; in a similar way bushes or even standards of Prunus pissardi give a rich effect when intergrouped with Cornus Spathii aurea in the proportion of three cornus to one of prunus. Spiræa arguta, or any similar dwarf white-flowered shrub, gains in effect when seen under tall pink or scarlet thorns. Forsythia viridissima mixed with Ribes atrosanguineum gives a happy result, and for choice of an evergreen work Berberis Darwini among and in front of them. Masses of Berberis aquifolium are readily improved by having this ribes and Forsythia suspensa in free groups through it, and plenty of Pinus montana behind. Pyrus floribunda, atrosanguinea, and spectabilis are good alone in grass, or when carpeted by dwarf ericas, while interplanted in beds with Hydrangea paniculata grandiflora ensures a due complement of flower in autumn as well as spring.

The coloured forms of amygdalus, cerasus, and prunus are also suitable for massing by themselves in grass as bushes; while in standard form they can be used to advantage among broad masses of rhododendrons, broken by spiræas, philadelphus, and similar shrubs; while the effect is helped out by having copper beech in the near vicinity. Under certain conditions, tall trees of cerasus, crabs, amygdalus, and allied subjects can often be placed to singular advantage as foreground studies in the open. In broad glades of woods they appear to immense advantage, but then it is desirable to have some evergreen background, such as pinus afford. This contrasting element of the pinus is never more happily expressed than where the graceful outlines and sparkling silver bark of silver birch comes against them in sharpest relief, and if azaleas are added to the foreground and rhododendrons introduced in the immediate distance the result is a picture of infinite beauty.

Crabs, like John Downie, Dartmouth, Montreal Beauty, or tall trees of Acer negundo variegata, are also suitable for intergrouping with rhododendrons; while the evergreen section of the last-named, even when out of flower, should be given emphasis, as, by employing them as background for Japanese maples, magnolias, and tree ericas, the season of colouring from leaf and flower is greatly prolonged. From their commanding height, Genista cinerea, virgata, and Cytisus albus are excellent when rising above olearias, berberis, and similar shrubs, or with rugosa roses and Pinus montana on rough ground; while in beds Spiræa Thunbergi, Philadelphus purpurea maculatus, Deutzia carminea, and Olearia stellulata would be effective foreground shrubs to employ. Genista hispanica and Cytisus præcox are excellent on sharp ridges of ground with Berberis stenophylla towards the crown, while the foreground might readily be filled in with the various forms of cistus. Pyrus aucuparia would be a suitable tree to plant with them, or alternately some of tree forms of acacia. The perfect grace of brooms appeal with singular charm when overlooking a water scene. Simple arrangements consist of groups of Genista Andreana with rose Wichuraiana clambering through it, and Spiræa Antony Waterer running up deep from a narrow point with Spiræa ariæfolia massed behind; or Cytisus præcox and Firefly intergrouped with a deep mass of Spiræa arguta and an irregular point filled in with Cotoneaster congesta, having a group of Aralia spinosa standing away from the water edge and behind the spiræa. Tamarix are all good shrubs beside water in ground that is well drained, and appear to advantage when grouped with Electra rose or Cytisus Kewense to ramp through them; or, on raised points with Cotoneaster horizontalis in front, and escallonias behind, having some tall plants of amelanchier and a good group of exochorda with Juniperus tamariscifolia again leading towards the water. In such a position Ulmus Dampieri aurea would be most effective; the golden colour of the leaves attain their brightest development where the tree is given a damp situation. Unlike many of its class, the foliage does not burn under the hottest sun. In large areas the fastigiate growth of libocedrus, taxodium, and Lombardy poplar could readily be introduced, and so help to emphasise the more spreading character of other trees; so likewise trees of a weeping character, if sparingly used and always in positions of prominence; of the latter, Salix Babylonica and Caprea pendula are both good and distinct, and suitable for positions that are very damp.

A BEAUTIFUL ARRANGEMENT OF FINE CHRYSANTHEMUMS

That was staged by Mr. Norman Davies at the Crystal Palace on November 1, and secured the National Chrysanthemum Society's large Gold Medal, and also the handsome Gold Medal offered by Messrs. Clay and Son for the best non-competitive exhibit in the show.

Grouping trees and shrubs affords unlimited scope for the expression of individual taste; a subject so comprehensive cannot, however, be adequately treated in these short notes, which must only be accepted as suggestive of greater possibilities.

L. O. V.

ANTHURIUMS.

This genus contains some 150 species and varieties, nearly all requiring stove treatment. Apart from the extreme beauty of the spathes of many of them, and their usefulness for decorative purposes, a few are worthy of a place in warm houses on account of their richly-marked foliage, which attains noble proportions. Warmth is essential to their successful cultivation, and during the growing season the temperature should range from 70 to 80 degrees, and an atmosphere highly charged with humidity be maintained. For the early winter months, when the plants are partially resting, a lower temperature will suffice, and the atmospheric moisture be considerably lessened, but at no time must the plants be dried off or kept in a low temperature.

When in full growth, anthuriums should receive copious supplies of water, both at the roots and overhead. Rain water should be used for syringing, and it should be of the same temperature as the structure in which they are growing, and the paths and stages should be damped at frequent intervals throughout the day.

The best time of the year for repotting is early in February, when the new growth is commencing. Rather deep pans are preferable to pots, as nearly all the roots keep near the surface of the soil. These should be quite clean, and be filled to within four inches of the rim with large pieces of crock, placing over these some nodules of charcoal, then a good layer of moss to prevent the compost mixing with the drainage. The compost should be used in a lumpy condition, and consist of equal parts fibrous peat and loam, with a liberal addition of chopped sphagnum, broken charcoal, and coarse sand. Take the old ball of soil and carefully remove with a pointed stick a portion of the old soil; then spread the roots in the new material, pressing firmly as the work proceeds, and round off the surface, keeping the base of the plant several inches above the rim of the pan or pot. Plants not requiring an extension of root room may be top-dressed with fresh soil after seeing that the drainage is in an efficient condition.

The best of the anthuriums I have grown for their spathes are A. Scherzerianum, in its many forms, notably Maximum, Wardi, Williamsi, and Rothschildianum, and A. Andreanum, A. Ferrierense, A. Lindenianum, A. ornatum, and A. floribundum. Of varieties grown for the beauty of their foliage alone I recommend A. Veitchi, A. Warocqueanum, A. crystallinum, and A. splendidum.

H. T. MARTIN.

Ripe Grapes.—Those still hanging in late houses must be kept at as even a temperature as possible, more especially now we have had a heavy downpour of rain, which has reduced the outside temperature to the normal for the time of year. Outside borders should be protected. Many have to keep grapes hanging to the New Year, and I have not found this any detriment to successful cropping, especially with that sterling variety Lady Downes, which improves with hanging until that time; but softer-skinned grapes should all be used before then. Muscat of Alexandria I have had to keep until the middle of March, though by that time they had begun to shrivel. A little ventilation, and just a little fire heat, to keep a temperature of 50 to 55 degrees, will keep the fruit. Empty the water tanks, as all moisture should be carefully avoided in a ripe house of grapes. When a good grape room is provided cut all bunches from mid-season houses, place one end of the growth in the neck of the bottle, which should be filled with clear, soft water. By this method grapes can be kept for a considerable time. Keep the room at amout 50 to 55 degrees.—W. A. COOK.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CŒLOGYNE CRISTATA.—Most of the varieties of C. cristata will now have completed their growth, and some of the early-flowering kinds will be advancing their flower scapes. Where plants are cultivated under favourable conditions, there is little difficulty experienced in the satisfactory development of the flowers. During the winter and early spring of last year, flower scapes were sent me from different sources asking why these had turned black, and become, in some cases, a black pulpy mass; at the same time it was stated that the plants appeared to be in perfect health. Most of my correspondents were amateurs, growing their plants in the neighbourhood of London and other large towns. Having had several years' experience in the London atmosphere, there was little difficulty in tracing the cause, as their experience in most respects corresponded with my own, and notes on this matter may be found in my earlier contributions to the Gardeners' Magazine. It is rarely, indeed, that C. cristata can be induced to produce its flowers satisfactorily the plants are grown to produce blooms in December, January, or the early part of February. I found that the only means of producing satisfactory results was by placing the plants in the odontoglossum house as soon as the pseudo-bulbs had matured, and permitting them to remain until there was the least possibility of their being affected by the influences of fog, thus retarding the flowering until more favourable conditions prevailed. This proved the only satisfactory way out of the difficulty. Such varieties as C. c. alba, which are naturally late in growth and flowers, are not subject to these unfavourable influences, and bloom without difficulty. Do not over-water the plants during the time they remain in the cool house. It will be found that there is almost sufficient moisture in the atmosphere to keep the pseudo-bulbs plump. See that all the plants are clean and free from scale now that they have reached maturity.

CATTLEYA LABIATA and other late autumn and winter-flowering kinds should be top-dressed or repotted as necessary, as soon as they pass out of flower. The root in many cases will have become well advanced, but with care repotting may be done, while there will remain sufficient active roots to enable the plants to become re-established. Careful watering is required for all plants that are subjected to repotting during the winter months, as only sufficient is necessary to keep the leaves and pseudo-bulbs plump, and encourage root action. Lightly spraying the plants overhead is a good practice when the conditions are favourable to rapid evaporation of moisture. Syringe between the pots daily and keep a reasonably humid atmosphere around fresh potted plants, as this will greatly reduce the necessity of root watering. — H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

PLUMBAGO ROSEA. — Although this species of plumbago is often grown in the stove, it can be grown equally as well in a temperature of 50 to 55 deg., and allowing for a few degrees rise in the day time. Now that they are coming into flower, a nice light position close to the glass should be afforded them to enable the flowers to receive all possible aid to develop that beautiful delicate colour of which they are capable of producing. If the atmosphere of the house is kept rather dry the flowers will last much longer. A very pleasing effect may be obtained in dinner-table decoration by associating the cut flower of Plumbago rosea with lily of the valley and trails of smilax or Asparagus Sprengeri.

RICHARDIA.—The arum lily is by nature an aquatic plant, and the plants being now in full growth they will require a liberal quantity to satisfy them. Frequent waterings of weak farmyard manure will be found very beneficial. Greenfly is apt to be troublesome, but an occasional fumigation will effectually check the pest.

HYDRANGEAS. — The exceptional hot summer just experienced has had a very good effect on hydrangeas by ripening the wood especially well, so that the growths look promising for another season. The larger specimens may be wintered in a cold peach case, and the small plants in frames, but in both cases protection during severe frost must be provided. Very little water is necessary during this period of rest, only sufficient to prevent the soil becoming dust dry, as excessive moisture will cause the buds to decay.

BULBS, FORCING PLANTS, ETC.—Bulbs still under cover must be regularly examined and removed when in a fit state. A full circulation of air must be allowed, to assist them in making strong growth, which is necessary to secure the best results in flowering. The earlier batches of freesias, Roman hyacinths, narcissus, and tulips have now made considerable root progress, and may be brought into gentle heat. Quick forcing is to be condemned, as this only tends to the production of poor flowers, and, especially in the case of narcissi, the flower spikes are apt to become blind. A little forethought exercised will make quick forcing unnecessary. The amount of heat may be increased when the flower spikes begin to show themselves. A few of the different flowering shrubs may be brought into a moderate heat to supply material for Christmas decoration when so much is required. Lilacs in variety are always acceptable at this season, also the earlier varieties of Azalea indica, such as Deutche Perle, Fielder's White. All these forced plants will continue in bloom much longer if gradually hardened off before the flowers are fully expanded.—A. Grubb, Porter's Park Gardens.

HARDY FRUITS.

PRUNING APPLE TREES.—Much has been written on the art of pruning fruit trees, and many beginners have attempted to follow out instructions so minutely given, but in many cases are disappointed with the result, as there are so many difficult varieties of apples, and these so diverse in habit of growth and mode of fruiting. It may safely be said that, with bush and trained trees, pruning in the majority of cases is carried to excess. In the case of vigorous growing varieties the mistake is often made of cutting all strong growth hard back to two eyes, or what not, only to make the trees throw out still more vigorous growth the following season. If, instead of this close cutting, an even distribution of young growths were left, say, six or eight inches in length, for one season, numerous fruit spurs will be formed, and the trees by this treatment alone would, in many cases, be brought into bearing.

YOUNG TREES.—A word of warning may also be given as regards the management of young apple trees. After these are once formed, that is to say, after a dozen even leads or so have developed, according to the form desired, if the trees are healthy these leads will make upwards of two feet of growth each season. Now, this natural desire to become a full-grown tree should be fostered as much as possible by leaving the leads quite two-thirds their length. This will prove beneficial all round; the trees will come into bearing soon, and a greater quantity of fruit can naturally be expected from a large tree than from a small tree; the over-abundant side growth will also be much less than that found in young trees that are annually hard pruned.

PLUM TREES ON WALLS.—These often get out of bounds, and fruitless, through making too much gross growth. In such cases, if the trees are not too old, the best remedy is to lift the trees entirely, cutting all the strong or injured roots with a sharp knife three or four feet from the stem, according to their size. When replanting, keep the roots as near the surface as possible, using lime, and grit in some form, to keep the soil sweet and open. The branches should be lightly secured to the walls so that the ties will allow the trees to settle down with the soil, and at all times the soil should be worked well among the roots and made quite firm.

YOUNG STANDARD FRUIT TREES.—Attention should be given to young standards in the way of new stakes, and ties, so that they may be secure from damage by the winter gales. Protection in many cases will also be needed against the ravages of hares and rabbits during hard weather. This may be procured by using wire netting, or, more simple still, birch or other twigs may be bound round the base of the trunks to keep them from gnawing the bark.—J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

FRENCH BEANS.—In order to keep up a successional supply of this valuable vegetable make another sowing in pots to succeed those sown late in September or October. A heavy yield cannot be expected from this planting, as it will be subjected to short, cold, and often sunless days. To mitigate this trouble to some extent, where means are at hand, grow the crop in a low, light house, where a genial atmosphere of 65 to 70 deg. can be maintained without having to resort to excessive artificial heat. Use smaller pots than usual, seven-inch are large enough; have them thoroughly drained, and secure a light open friable soil. Carefully water it at all times. A judicious syringing of the plants on warm days will greatly aid successful growth.

PARSNIPS.—These will have practically finished their growth, and it is generally admitted that exposure to frost improves their eating qualities. But as the weather from now cannot be relied upon, it is advisable to take advantage of a favourable opportunity to lift at least a portion of the crop. If stored in sand in the root house they will be at command for present use. Should part of the crop be left in the ground it will not harm, but possibly improve.

CHICORY.—This will in most establishments be largely used for salad purposes during the winter and spring months. It is the custom with many to have an early and a later batch of plants. The earlier ones now will have formed large and plump crowns, which, if placed in the mushroom house, in boxes, or planted out, will yield good and succulent leaves. It is well also to have a stock of crowns lifted, and stored in ashes or sand in a sheltered position outside.

CUCUMBERS.—Plants that were put out as advised will now be fruiting, and need careful attention to keep them in a healthy vigorous condition. Frequent light applications of rich loam, accompanied by a mild artificial manure, such as Clay's, will much assist them. Avoid taxing the strength of the plants by over-cropping, and keep the atmosphere of the house balanced with moisture according to the weather. On sunny days syringe freely to remove all insect pests.

MUSHROOM BEDS.—If the demand is continuous, collect material for beds to be made, one for each month. This must be frequently turned until thoroughly sweetened. Make the bed firm by treading, and allow the heat to decline until the temperature is down to about 85 deg., when it will be ready for spawning. Any beds that are failing prematurely may be strengthened by watering them with warm water, to which salt is added; liquid stable manure, diluted with warm water, will also serve to advance the crop.

GENERAL REMARKS.—Sharp frosts may be very damaging from now onwards. The protection of all sadalling, etc., should be completed; make frequent sowings of mustard and cress in boxes, and place these in a temperature of about 60 deg. during the early stages; afterwards they may be placed in cooler quarters until required for use.—Charles Flack, Cholmondeley Castle Gardens.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, November 7.

Present: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair); Dr. A. Voelcker, Sir Everard im Thurn, Messrs. W. E. Ledger, J. Fraser, G. Wilson, J. W. Odell, G. Gordon, V.M.H., J. T Bennett-Poë, V.M.H., W. C. Worsdell, E. M. Holmes, W. Hales, W. Fawcett, J. O'Brien, A. W. Sutton, V.M.H., R. Hooper Pearson, A. Worsley, R. A. Rolfe, and F. J. Chittenden (hon. secretary).

OCTOMERIA SP. — Dr. Rendle reported that the octomeria referred to him at the last meeting, and shown under the name Octomeria Baueri, did not agree with the figure given by Bauer. Mr. Rolfe recognised it as O. crassifolia, a Brazilian species, described by Lindley, with whose type specimen in the Kew Herbarium it agrees well.

CROSSES WITH PEAS.—Mr. A. W. Sutton gave an interesting account of his experiments in crossing a pea, which he found in Palestine in 1904, with forms of our cultivated peas. The plant found was a weak-stemmed plant, about 3ft. in height, and bearing very small, blunt pods. It had no purple colour in the leaf axils, and was, therefore, supposed to be white-flowered (the plants being past flowering), and seed was collected. The seed was olive-green, heavily mottled with brown, varying to a dark brown. The seedlings raised in England had serrated leaflets, self (not bi-) coloured magenta flowers, but no colour in the leaf axils; the pods were small and obtuse, and curious in containing a white, woolly substance, similar to that contained in the pods of beans. It appeared to resemble, in some measure, Pisum quadratum, which he had obtained from Kew; but in that the flowers are bicoloured, the leaflets entire, the seeds rounder, and not so dark in colour. In addition to these two, the only pea with bi-coloured flowers and no colour in the leaf axils known to Mr. Sutton is one obtained from Svalof, under the name of Solvart. With the idea of discovering whether this wild form could be the ancestor of our white-flowered culinary pea (Pisum sativum) or the bi-coloured field pea (P. arvensis), which some consider varieties of one species, Mr. Sutton made about 40 crosses with various forms, but in only four cases was it possible to grow the hybrids to F_2, or further, in two of which one of the parents was a variety of P. sativum, and in two varieties of P. arvense. In all the others sterility manifested itself, and the varieties were lost; but in the four crosses mentioned more or less perfect fertility seems to have been achieved. The crosses were made with the sole idea of discovering the relationship the Palestine Pea had to commercial peas. Five crosses were made with round-seeded, white-flowering varieties (P. sativum), and sterility preprevented them being grown to F_2, similar results attending eight crosses made with wrinkled-seeded, white-flowered peas. Six crosses with round-seeded, white-flowered, umbellate peas (P. sativum umbellatum) gave only one that has continued fertile. Five crosses made with the degenerate types which constantly occur among cultivated varieties of P. sativum, gave only one which has continued fertile. Sixteen crosses with bi-colour-flowered types (P. sativum) resulted in only two which have continued fertile. The F hybrids were, as a rule, taller than the Palestine pea, and had leaflets more or less serrated; the flowers were bicoloured. In F_2 plants, with white flowers and entire leaflets occurred, but none were found resembling the Palestine pea, but with white flowers. It would thus appear that the pea occurring wild in Palestine is not the plant from which our cultivated forms have been derived. Mr. Sutton exhibited seeds of the wild form and of the cultivated ones with which it was crossed. It was unanimously resolved, on the motion of Mr. Holmes, seconded by Mr. Bennett Poë, to recommend the award of a Certificate of Appreciation to Mr. Sutton for his work in connection with these peas.

INTERESTING ORCHIDS.—Mr. J. O'Brien showed some interesting orchids on behalf of the Rev. Mr. Fletcher, including Bulbophyllum Medusæ, Catasetum Gnomus of Reichenbach, and a species of epidendrum, which Mr. Rolfe later identified as E. Harrisoniæ, Hook (Bot. Mag., t. 8,392), a native of Brazil, and a somewhat variable plant.

MALFORMATION OF CATTLEYA LABIATA.—Mr. G. Wilson showed flowers of Cattleya labiata showing false peloria, produced on a plant which each year produces malformed flowers, though not always malformed in the same fashion as in the present case.

CEROPEGIAS.—Mr. Ledger exhibited a flowering spray of Ceropegia Rothii x Gürke, new hybrid. Raised by Dr. Paul Roth, of Bernburg, from seed obtained in 1908 by crossing C. Sandersoni, Hook, with pollen of C. radicans, Schleet, two South African species. A twining succulent, with fleshy leaves, intermediate between both parents. The flowers resemble those of the seed parent in colour, but the umbrella-like apex in that species is here modified to erect, replicate lobes, cohering at the top, somewhat as in C. hybrida, N. E. Br. (in "Gardeners' Chronicle," December 8, 1906), a flower of which was also shown. Mr. Ledger stated that, in describing the last-named plant, Mr. N. E. Brown drew attention to the peculiar structure of the asclepiads, unique among dicotyledons in having the pollen agglutinated into a waxy mass, and so placed that fertilisation would seem to be only possible through insect agency, and that to do so artificially would, if at all possible, prove a very delicate and difficult operation. Dr. Roth has, however, successfully accomplished, in this instance, the first artificial hybridisation to record in the genus Ceropegia. The plant is described in "Monatsschrift für Kakteenkunde," for January, 1911, pages 8-9. Mr. Dedger also showed a flowering spray of C. Rendallii, N. E. Br., a slender-growing, tuberous-rooted species. The corolla lobes of the delicate and beautiful flowers are united into an umbrella-like canopy, of a bright-green colour, supported in five short stalks over the mouth of the tube, which is white in the upper part and grey-green in the inflated base. This species belongs to the section which includes Sandersoni, Montiroæ, and the not-yet-introduced fimbriata. C. Rendalli was first sent to Kew, early in the year 1894, by the late Dr. P. Rendall, of Barberton, after whom it was named. ("Kew Bulletin," No. 87, March, 1894, 100.) Long lost to cultivation, a tuber (without name) was sent in 1908 by Mr. George Thorncroft, of Barberton, to the late Mr. W. E. Gumbleton, who presented it to Mr. Ledger, and from which all the plants at present grown are derived. Mr. Ledger has raised a hybrid from C. Barklyi, Hook, f., fertilised, in 1909, by pollen of this species.

National Hardy Plant Society.

The first annual meeting was held at Birmingham on November 7, Mr. A. J. Macself in the chair, and a good attendance. The annual report of the Council was submitted.

The death of two vice-presidents, the Earl of Onslow, G.C.M.G., and William Edward Gumbleton, Esq., J.P., F.R.H.S., was recorded with regret. During the year the society had sent deputations, awarded certificates of merit and medals to the following shows: York Gala, Hanley Floral Fête, Leamington and County Show, Cardiff, Abbey Park, Leicester, and Harrogate. A conference was held at Shrewsbury, where interesting papers were read. The Council had decided to hold a show at the Royal Horticultural Hall, Vincent Square, on June 19, 1912, and had received a considerable number of promises of exhibits and donations to the expenses. An invitation to send a deputation to the Dublin Spring Show in 1912 had been accepted. The honorary solicitor had given advice to a number of members on various points of law relating to horticulture.

The thanks of the society were due to the officers and members who attended the various deputations, to Sir Frank Crisp for entertaining the society at Friar Park, and to the Gardeners' Magazine, Mr. R. Pinches, and Dr. MacWatt for gift of medals, also to the chairman, honorary secretary, Mr. W. H. Paine, and other members who had lectured to sister societies on hardy flowers. A model schedule had been prepared by the chairman and adopted by the Council, which was ordered to be printed and forwarded to all the leading horticultural societies. On the proposition of Mr. Hawes, seconded by Mr. Hosier, the annual report was adopted, and ordered to be printed.

The Treasurer submitted a balance-sheet, showing receipts of £56 4s. 6d. and expenditure £53 3s. 10d., leaving a balance in hand of £3 0s. 8d. The balance-sheet was adopted. The following officers were elected unanimously: Chairman, Mr. A. J. Macself; vice-chairmen, Mr. R. Pinches, Dr. MacWatt, and Mr. W. H. Paine; hon. secretary and Solicitor, Mr. Frank Bouskell. A Council was also elected.

A vote of thanks was accorded the officers and Council for their work during the past year, and to Mr. Leopold Ray for his loan of room for meetings. It was decided to print 500 copies of the annual, which was ready to put in the printers' hands. This concluded the business of public interest.

Cambridge Horticultural Society.

CUT BLOOMS.

The annual autumn exhibition of this society was held in the Corn Exchange on the 8th inst., and proved highly successful. There was an exceptionally fine display of hardy fruits, and chrysanthemum blooms were of superb beauty.

The numerous classes for cut blooms were hardly so well filled as at some of the previous exhibitions held at Cambridge, but the quality was exceedingly high throughout, and not a few of the blooms in the winning stands were so splendidly developed that they are not likely to be surpassed this season. In the great open class for twenty-four blooms of Japanese varieties, Mr. G. Barker, gardener to Miss Gibson, occupied the place of honour with magnificent blooms of Evangeline, Reginald Wallis, Lady Talbot, Miss Ettie Green, Duchess of Sutherland, Master James, Frances Joliffe, Edith Jameson, Rose Pockett, Miss A. Lunt, Rose Ellis, Mrs. F. C. Stoop, Gladys Blackburn, Lady E. Letchworth, Henry Poulton, Mrs. A. T. Miller, Frank Payne, Valerie Greenham, C. H. Totty, Madame G. Rivol, Hon. Mrs. Lopes, F. W. Lever, and Miss Trevor Williams, the distinctive colouring of the last-named being especially well developed; Mr. R. Smith, gardener to G. R. C. Foster, second, with an attractive board of blooms. In competition for the prizes for eighteen varieties of Japanese, Mr. Barker was again first, staging large, richly-coloured and finely-finished blooms; Mr. R. Smith was again second.

There was a spirited contest in the class for twelve blooms of Japanese varieties, and at the head of the several competitors was Mr. E. Dyson, gardener to W. R. Neal, Esq., who staged blooms equally remarkable for their large size and excellent finish; Mr. Kemp, gardener to Professor Waldstein, followed closely for second place; and Mr. R. Smith, who was third, had an excellent set of blooms. Mr. A. Dyson occupied the first place in the class for six blooms of Japanese varieties, closely followed by Mr. W. Hall and Mr. R. Smith, who were second and third respectively. Mr. W. Hall had the best three blooms of Japanese, and Mr. A. Dyson was second.

It is a rare occurrence to see such splendidly developed blooms of incurved varieties as those with which Mr. G. Barker obtained premier honours in the class for eighteen blooms, and the exhibitor may be heartily congratulated on the success he achieved. The varieties represented comprised Nellie Threlfall, Godfrey's Reliance, Marjorie Shield, Buttercup, Mrs. C. Crooks, Clara Wells, Miss

C. Stoop, Mrs. B. Hankey, Edwin Thorp, Godfrey's Eclipse, Mrs. J. Wynn, Laura Giles, Mrs. G. Denyer, W. Biddle, H. W. Thorp, Embleme Poitevine, Lady Isabel, and Romance; Mr. T. Todd, gardener to W. A. Briscoe, Esq., with medium sized blooms of excellent quality, was second. Mr. Barker was first also for twelve incurved with superb blooms, and Mr. T. Todd followed closely for second place. Mr. A. Dyson was first for six and for three incurved with neat, well-finished blooms.

A considerable number of classes were provided for blooms in vases, and as the entries were numerous in each, the blooms staged in vases formed an important and highly attractive feature. In the class for six vases of Japanese, three blooms in each, Mr. G. Barker was first with magnificent specimens, those of the Hon. Mrs. Lopes and G. J. Hamand being of quite exceptional excellence, those of the first-named having a depth of about twelve inches; Mr. R. Smith second. The same exhibitors occupied similar positions in the class for six incurved, both staging well, but the blooms in the first prize vases were fully equal in size and finish to those Mr. Barker had in his winning collection of twenty-four. The varieties were Mrs. P. Denyer, Mrs. J. Wynn, Miss Stoop, Nellie Thretfall, Embleme Poitevine, and Duchess of Fife; Mr. T. Todd second.

The contributions to the classes for decorative varieties, to be shown in vases, produced a tasteful and attractive display. The contest was spirited in the class for six vases of decorative varieties grown without having been disbudded, and at the head of the several exhibitors was Mr. A. Lelliott, who had well-developed and remarkably fresh blooms of well-known varieties; Mr. A. Pepper, gardener to A. Kurrell, Esq., was a close second with good vases, although somewhat unequal; Mr. Edwards followed very closely for third place. The single varieties shown in vases produced a bright display, and in the class for six varieties Mr. W. Dobbs occupied the post of honour with blooms of rare excellence; Mr. W. Hall was a capital second, and Mr. T. Todd third.

PLANTS.

Specimen chrysanthemums were shown in finer condition than we have previously seen them at Cambridge, and constituted an attractive feature. For six Japanese varieties, Mr. George Willers, Trumpington Road, was first with large, freely-flowered bushes, and the same exhibitor was also first in the class for three specimens of Japanese varieties with remarkably fine examples. In the single specimen classes Mr. Willers was first for Japanese for pompon and for reflexed. For a specimen of a single variety Mr. Dyson obtained premier honours, Mr. Willers following him closely for second place.

In the classes for miscellaneous plants Mr. R. Smith scored for six specimens of Begonia Gloire de Lorraine, and Mr. Dyson for three salvias, which made a brilliant display of colour.

FRUIT AND VEGETABLES.

Fruit was shown in immense quantities and in splendid condition, the apples being especially noteworthy for their brilliant colouring. In the whole of the thirty odd classes the competition was very spirited, and especially was this the case in the class for twelve dishes of apples to comprise an equal number of dessert and cooking varieties. Mr. A. Lelliott was first in this class with superb fruit of Allington Pippin, Peasgood's Nonsuch, Blenheim Pippin, Bismarck, Emperor Alexander, Cox's Pomona, Mabbott's Pearmain, King of the Pippins, Gascoyne's Scarlet, James Grieve, and Cox's Orange Pippin. Mr. J. H. Ridgwell, Histon, was a close second, with remarkably fine fruit, and Mr. T. Todd was third. For six dishes, three each of cooking and dessert varieties, Mr. R. Stephenson scored with large, brilliantly coloured fruits. Mr. N. Neaves, gardener to W. R. Hollis, was second, and Mr. T. Todd third. For three dishes of dessert apples Mr. R. Stephenson scored with Cox's Orange Pippin, Blenheim Pippin, and King of the Pippins at their best; Mr. Neaves second. For three dishes of cooking apples Mr. R. Stephenson was first with large richly-coloured fruit of Lane's Prince Albert, Bramley's Seedling, and Bismarck. Mr. T. Todd second.

Pears were splendidly shown, both as regards numbers and quality. Mr. T. Todd obtained premier honours in the class for six dishes with fine fruit of Beurre Diel, Doyenne du Comice, Durondeau, Beurre Bose, Beurre Bachelier, and Duchesse d'Angouleme. Mr. Todd was a capital first in the class for three dishes.

The classes for baskets of cooking and dessert apples, containing 20lb. each, were well filled, and the contributions formed an attractive feature. In the class for cooking apples, Mr. Neaves was first with Newton Wonder in superb condition, and Mr. R. Stephenson was second with finely-coloured Bramley's Seedling. In the corresponding class for dessert varieties, the exhibitors last named was first with Cox's Orange Pippin, and Mesrs. Jones and Son were a very close second with the same variety.

Grapes were of average merit, and Mr. W. Hall was first for Muscat of Alexandria, Mr. R. Smith first for Alicante, and the Hon. Mrs. Knowles Thornton first for any other black with Gros Colmar.

Vegetables were plentiful and good, and the contributions to the classes for collections were sufficient to make an interesting exhibition. The Hon. Mrs. Knowles Thornton occupied the premier place in the class for ten kinds, and Mr. A. Howell was a close second. The exhibitor last named was first in Messrs. E. Webb and Sons' class for six kinds, and Mr. R. L. Hudson was second, both staging produce of great excellence. In Messrs. Sutton and Sons' class for six kinds Mr. Murrell and the Hon. Mrs. Knowles Thornton were first and second, both staging collections possessing much merit. Potatoes were largely and well shown, and Mr. W. Todd was first for twelve and six dishes with exceptionally fine tubers.

Liverpool Horticultural Association.

NOVEMBER 8 AND 9.

The thirty-second autumn exhibition was held in the Corn Exchange, Liverpool, under favourable climatic conditions, the exhibits showing to great advantage in the well-lighted hall. The entries were fully up to the average, both in quantity and quality. The cut flower section caused considerable surprise, the flowers being the best yet staged, notwithstanding the general report that blooms were distinctly below the average.

CUT FLOWERS.

The chief prize for thirty-six blooms, eighteen Japanese and eighteen incurved, brought five competitors, the position of honour being gained by Mr. C. Groves, gardener to Sir Gilbert Greenall, Bart., Warrington, for a very fine stand, his finest flowers being Eclipse, Frances Joliffe, Mrs. A. T. Miller, Hon. Mrs. Lopes, Mrs. A. S. Bott, Buttercup, Embleme Poitevine, W. Biddle, Pantia Ralli, and Clara Wells. Mr. R. Nisbet, gardener to Sir W. Bass, Bart., Burton-on-Trent, second, with a splendid even stand of Japanese; this exhibitor secured the special awards for the best blooms in the show with Mrs. W. B. Marsham (Japanese) and Godfrey's Eclipse (incurved). Mr. G. Haigh, gardener to Sir W. H. Tate, Bart., Woolton, and Mr. H. Osborne, gardener to R. R. Heap, Esq., took the remaining awards.

For eighteen incurved blooms, Mr. J. George, gardener to T. Henshaw, Esq., led with a good even stand. For twelve blooms Mr. J. Clarke, gardener to Mrs. Clark, Allerton Hall, proved the victor, and for similar classes of Japanese blooms, Mr. C. Goves and Mr. J. Copple, gardener to H. Belk, Esq., Theyton, proved the leaders.

PLANTS.

For three large-flowered trained chrysanthemums Mr. T. Hitchman, gardener to A. Earle, Esq., Childwall, led with excellent examples, Miss Lilian Early being noteworthy. For one trained specimen the same exhibitor excelled with a fine Mrs. Acland. For three singles, trained, Mr. F. Atkin, gardener to T. W. Wright, Esq., won with charming models, and the same exhibitor also led for one pompone trained. For six singles, staked, Mr. E. R. Finch, gardener to W. J. Lockett, Esq., won. Mr. Hitchman scored with three large-flowered, and one staked plants, and for the group Mr. F. Atkin scored with good single flowers, arranged rather formally.

Miscellaneous plants were staged in considerable numbers, but only the chief classes are here noted. For one orchid Mr. T. E. Elsworthy, gardener to W. L. Gladstone, Esq., won with a well-bloomed Cattleya labiata; for three orchids, Mr. P. Jakeman, gardener to Sir W. B. Forwood, Bart., took leading honours, having Cymbidium Traceyanum with five good spikes. For two palms Mr. F. Atkin led with excellent specimens, and for one fern Mr. G. Eaton, gardener to W. Tod, Esq., led with Davallia figensis plumosus, nine feet in diameter.

FRUIT.

For six dishes of dessert fruits Mr. R. Jones, gardener to J. Amplett, Esq., led, his set including highly-coloured bunches of Muscat of Alexandria grapes. For four bunches of grapes Mr. Elsworthy was to the fore. Two buches Black Alicante grapes found Mr. J. Barker, gardener to J. W. Raynes, ahead with good clusters of finely coloured berries. Mrs. Kendall led with Barbarossa for any other black grape. For two bunches of Muscats, Mr. Thomas Barclay, gardener to Mrs. Cook, won with long, richly-coloured bunches, and for two bunches of any other white grape, Mr. T. Elsworthy was first with Golden Queen.

NON-COMPETITIVE.

As usual many excellent non-competitive exhibits were staged.

Gold Medal. — Messrs. Mansell and Hatcher, for orchids; Mr. J. Lee, for a large exhibit of apples of good quality.

Silver Medal.—Messrs. R. P. Ker and Sons, for cyclamen, palms, begonias, etc.; Messrs. Fishlock Bros., for cut flowers; Messrs. Wells and Co., for chrysanthemums; Liverpool Orchid Company, for orchids.

Paris Autumn Show.

The annual autumn exhibition of chrysanthemums, fruit, etc., held by the National Horticultural Society of France, in the Cour-la Reine, Paris, was opened by President Fallieres on the 2nd inst., and closed on the 12th. As usual, the show was a very large and comprehensive one, and there were many entries in the various classes. The visitors were numerous, and, although the society has now to provide a temporary structure in which to house the exhibits, the work is carried out in the most satisfactory manner, and a fine show provided. The Floral Committee met the day preceding the opening, when the new seedlings were submitted and many Certificates awarded. The following raisers were the most successful, viz., Calvat, Chaubrier, Vilmorin, Nonin, Marquis de Piris, etc. Altogether about forty-five awards of Certificates were made.

The jury met on the morning of the opening day, and, after making the awards provided for by the schedule, were entertained at lunch at Ledoyen's Restaurant, Champ-Elysées. M. Viger took the chair, being supported by the officers of the society, and a company of about 200 guests. The usual complimentary speeches were made by the representative of the Minister of Agriculture, the President of the Paris Municipal Council, M. Lepinè, the Chief of Police, M. Viger, M. Deloncle, the Deputy for the Seine, and Mr. Harman Payne.

Returning to the show, the visitors proceeded along the promenade leading from the entrance to the exhibition building. Here there were many groups of trained fruit trees and ornamental shrubs, such as is cutomary at the Paris Show, and were in the main exhibited by Messrs. Barbier, Martin-Lecointe, Paul Lecolier, Boucher, Croux, Moser, Kieffer, Nomblot-Bruneau, Monnier, and others.

We no sooner set foot inside the show than we were attracted by the exhibit of M. Opoix, of the Luxembourg Gardens, whose fine collection of fruit filled the ante-room, and was placed in huge semi-circular piles on tables all round the room. Apples and pears predominate, some for variety being shown in pretty baskets tied up with coloured ribbon. Going still further we see many more very large exhibits of this kind. Specially meritorious from the point of view of size and quality were those sent by M. Lequeen, an enormous run of pears in boxes from M. Nomblot-Bruneau, M. Masle, M. Deschamps, the Ecole Horticol de Plessis-Piquet, M. L. Gronas, Duclos, Carnet, and others.

Other choice fruits, such as grapes, peaches, and the like, were mostly put up in plate-glass cases. The variation and artistic taste displayed in these exhibits was characteristic of the French. As we passed into the great exhibition hall we had to go through a kind of pergola formed of vine branches by Messrs. Salomon, of Thommery. Right and left were long cases filled with bunches of many different varieties of grapes for which the firm is noted. Dupont-Barbier set up a run of 60ft. of these cases filled with beautiful-looking fruit. Messrs. Cordonn ireet Fils had an equally fine exhibit, consisting chiefly of white and black grapes.

Chrysanthemums, of course, were the chief floral adornment of this great show, and there were most of the big growers present. The real centre of interest, however, was in Mr. Thomas Stevenson's (gardener to E. Mocatta, Esq.) accumulated group, which faced the main entrance to the inner hall. He entered in five classes, the whole being placed together, and a grand group it made. In each class he obtained the highest award. The finely-developed blooms of Japanese mingled with singles, and set off with Asparagus Sprengeri, and another greenery, delighted the visitors, who, it may be safely affirmed, had never seen anything like them before. Other exhibitors of cut blooms were M. Paul Labbe, M. C. Gervaiz, Henri Crépin, a nicely arranged lot in an oblong bed set off with musa, etc. M. Zimmermann won the Crepin challenge cup for a neatly-staged collection of cut blooms.

Plants in pots are always numerous, and generally of medium quality. The exception, however, was in the exhibits of trained specimens, which of late years have shown great ingenuity, the forms adopted being much more varied and quaint than ever we saw in this country when trained plants were more fashionable than now. A magnificent exhibit came from Messrs. Vilmorin. It was in two portions, each edged with a double row of dwarf plants of Dr. Geo. Barrie and Gerbe d'Or. Between the huge trained plants of square-shaped pyramids in the Japanese style and other forms, were placed small pots of lycopodium; Japanese and single varieties were mainly used.

Many curious forms were staged by M. Pinon, a specialist in this art. He had chrysanthemums trained in the form of Chinese pagodas, round tables, baskets, vases, stars, etc. Some good standards were shown by the Ecole Horticole of Plessis-Piquet. M. Montigny showed a group of 1911 novelties in great variety. From M. A. Nonin came two nicely arranged decorative groups, arranged on each side of the middle of the show. Among newer things we noted Marocain, a fine decorative Japanese, bright crimson-red with golden reverse. Bordeaux, a rich shade of purple amaranth shaded carmine, a well-built decorative Japanese, close and compact. In singles there were some neatly-built flowers of Oiseau bleu, Fontarabie, and Hendaye. Among new show Japanese, Chrysanthemiste Jondelier, a sulphur-yellow sport from President Loubet, received a First-class Certificate.

Considering the large number of other exhibitors, we cannot in the limited space at our command be expected to do justice to their exhibits. It must suffice to say that Messrs. Feron, Crepin, Mascaux, Ferard, Lazard, Morin, Merigeon, Combon, Legeard, and others all staged groups of more or less merit.

Other flowers, of course, were in evidence. The orchid room contained a small display, for us, from M. Reginer, a collection of Habenarias Regmeri with H. Militaris, a well-grown little lot. M. Beranek staged stove plants and exotic palms, a few good specimens of Cattleya labiata. In Messrs. Maron's group were Cattleya Ligury, and C. Fabia alba; also Lælio-cattleya Bright Star. Mr. Edward V. Low, of Haywards Heath, sent Cypripedium Germaine Opoix, Odontoglossum grande aureum Pitt's var., etc.

The entries in floral art make us regret that in our own International Show in May, 1912, there is no provision for such a display. The well-known houses of Lachaume and Debrie sent most decorative exhibits in their accustomed style, but which we are precluded from describing. M. H. Pillon had several pretty designs, one a bamboo arbour covered with chrysanthemums in flower.

Vegetables always occupy an important place at Paris. The size and variety of the exhibits are astonishing to those who are used to English shows only. The firm of Vilmorin, Andrieux and Co. made an immense display, including everything in season.

Manchester and North of England Orchid Society.

At the meeting held on Thursday, November 2, Z. A. Ward, Esq., Northenden (gardener, Mr. Weatherby), exhibited a fine group of over 150 plants, to which a Silver-gilt Medal was awarded, a special feature being a mass of 50 plants of Cyp. insigne Sanderæ; also a collection of Insigne vars., including Dorothy, Mollie Dow, Harefield Hall, Perfection "Ward's" var. (A.M.), Chantini, Lindeni, with C. Actæus "Ward's" var. (A.M.); and amongst the cattleyas were noticed C. Armstrongæ "Ward's" var., C. Armstrongæ var. Mrs. Ward (A.M.), and C. Williamsi (A.M., W. R. Lee, Esq., Heywood (gardener, Mr. Woodhouse), was also successful in obtaining a Silver-gilt Medal for a group, consisting of cattleyas and their hybrids, cypripediums in variety, and a nice batch of Dendrobium Phalænopsis Schroderianum. Cattleya Labiata W. R. Lee (F.C.C.), a fine white variety, C. Helène (A.M.), C. Mantini, and Lælia Bella (A.M.), were especially meritorious.

O. O. Wrigley, Esq., Bury (gardener, Mr. Rogers), was awarded a special vote of thanks for a very nice lot of Dendrobium Phalænopsis Schroderianum, including the var. Album, with two fine spikes, and a magnificent plant of Odontoglossum crispum, with a spike almost four feet long, carrying twenty-eight large flowers. J. McCartney, Esq., Bolton (gardener, Mr. Holmes), was awarded a Silver Medal for a group of Cattleya Fabia var. Prince John (A.M.), C. Dowiana aurea, Brasso-Cattleya Maroniæ, Cypripediums insigne Laura Kimball, etc. Colonel J. Rutherford, M.P., Blackburn (gardener, Mr. Lupton), was awarded a Bronze Medal for a group consisting of cattleyas and cypripediums. Rev. J. Crombleholme, Clayton-le-Moors (gardener, Mr. Marshall), was also awarded a Bronze Medal for a group of cypripediums.

Wm. Thompson, Esq., Stone (gardener, Mr. Stevens), showed Cypripedium Pyrrha Thompson's var. (A.M.), C. Baron Schroder Armstrong's var., C. Grittleton (Stevensi x Thompsoni Exquisitum, A.M.), and an unnamed variety of Spicerianum x Thompsoni (A.M.), along with a fine form of Odontoglossum crispum hololeuca Walton Grange var. J. J. Holden, Esq., Southport (gardener, Mr. Johnson), staged very fine examples of Cattleya Harrisoniæ alba, carrying two flower spikes; Cypripedium Gaston Bultee Holden's var., and C. Germain Opoix. G. H. Peace, Esq., Monton Grange (gardener, Mr. Mace), exhibited a fine plant of Oncidium ornithorynchum album, carrying several good spikes.

J. H. Craven, Esq., Keighley (gardener, Mr. Corney), staged very fine examples of Cypripedium eboriacum, C. Germain Opoix, C. Gaston Bulteel, etc. Messrs. J. Cypher and Sons, Cheltenham, were awarded a Silver Medal for a group of Cattleya Fabia, Oncidium Forbesi, Vanda cœrulea, and the interesting Dendrochilum Cobbianum, with cypripediums. Messrs. A. J. Keeling and Sons, Bradford, showed Cypripedium Mellone, etc. Messrs. Charlesworth and Co., Hayward's Heath, had Cattleya Lord Rothschild alba and C. Bola. Messrs. Stuart Low and Co., Bush Hill Park, staged four fine plants of Cattleya Fabia. Messrs. Hassall and Co., Southgate, had a pretty exhibit of hybrid cattleyas.

First Class Certificates were awarded to Cattleya labiata alba, var. Richard Le Doux, from R. Le Doux, Esq.—a very fine variety and large flower; to Oncidium ornithorynchum album, from G. H. Peace, Esq.; to Cattleya labiata, var. W. R. Lee, from W. R. Lee, Esq.

Award of Merit to Cattleya labiata, var Helène, and Lælia bella, from W. R. Lee, Esq.; to Cattleya Armstrongæ, Ward's var.; and C. Armstrongæ var. Mrs. Ward; C. Williamsi (Gaskelliana alba x Harrisonæ); Cypripedium Perfection, Ward's var.; and C. Actæus, Ward's var., all from Z. A. Ward, Esq.; to Cattleya Fabia, var Prince John, from J. McCartney, Esq.; to Cypripedium Pyrrha, Thompson's var.; C. Grittleton (Stevensi x Curtisi Exquisitum), C. Spicerianum x Thompsoni (unnamed), with Odontoglossum crispum hololeuca, Walton Grange var., from Wm. Thompson, Esq.

Windsor.

The annual autumn show, held in the Albert Institute on November 10, was a distinct improvement upon the displays held during the past few years. Although this society is a comparatively small one, it encourages features which we do not find so good at much larger shows. For instance, the groups of single-flowered chrysanthemums are a magnificent feature, thoroughly displaying these charming flowers to the fullest extent. Prizes are here offered, too, for a dozen large Japanese blooms in one vase or basket with any cut foliage, which produces a fine effect, and thus gives these large blooms an opportunity of showing to advantage as decorative flowers.

For a group of decorative chrysanthemums, not disbudded, arranged for effect, with an edging of ferns allowed, there were three competitors. Mr. G. West, gardener to F. Picardo, Esq., Old Windsor, was distinctly ahead with a group composed almost entirely of single-flowered varieties, the freely-grown plants carrying grand sprays of fully developed flowers of Gracie Lambert, Reginald Godfrey, Mary Richardson, Mrs. R. C. Pulling, and Sylvia Slade. Mr. W. Cole, gardener to Mrs. E. B. Foster, Clewer Manor, Windsor, was a good second with slightly inferior flowers. Mr. G. J. Hill, gardener to A. L. Wigan, Esq., third.

The leading cut bloom class was for eight varieties, three blooms of each in a vase, the coveted prize being the King's challenge cup with a cash award. Five entered, and Mr. C. Page, gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead, was distinctly ahead with finely-developed specimens of Evangeline, Miss A. Nicoll, J. Lock, Bessie Godfrey, Mrs. G. Mileham, Mrs. C. H. Lotty, Frances Jeliffe, and the Hon. Mrs. Lopes. Mr. H. Bowyer, gardener to Sir R. Harvey, Bart., Langley Park, Slough, was second with heavy flowers a little past their best. Mr. W. Holder, gardener to Mrs. Adair, Englefield Green, third. An interesting class was that for eighteen Japanese blooms, distinct, arranged in a space five feet by three feet, with foliage plants or cut foliage. Mr. H. Hearn, gardener to Mrs. Gerald Goodlake, Denham, led with capital specimens of Evangeline, Reginald Vallis, Mrs. A. T. Miller, Kara Dow, F. S. Vallis, G. J. Bruzzard, and the Hon. Mrs. Lopes, but with a little faulty arrangement. Instead of placing the blossoms in triplets they should have been more widely displayed. Mr. A. R. Allan, gardener to Lord Hillingdon, Hillingdon Court, Uxbridge, second, with a neat arrangement of smaller blooms. Mr. Holder was third. Mr. C. Page secured the leading award for twelve Japanese, distinct, with handsome specimens of popular varieties; Mr. H. Bowyer a good second.

Incurved varieties were well displayed by Mr. Page in the class for twelve, distinct; Mr. R. Brown, gardener to Lady Tress Barry, second. Mr. West won for six incurved, any one variety, with quite shapely specimens; Mr. Page second.

For a basket or vase of twelve blooms arranged with any natural foliage, there was a strong entry, and Mr. Hearn, with exceedingly fine specimens of such sorts as Reginald Vallis, F. S. Vallis, and Mrs. A. T. Millar, arranged lightly with highly-coloured autumn foliage, scored; Mr. C. Page second with flowers not quite so fine, but effectively arranged with berberis and spiræa sprays; Mr. R. Brown third. Single-flowered varieties in sprays are here a strong feature. For six varieties, not disbudded, five sprays of each, ten entered, and Mr. G. West was the most successful with finely-developed blooms of Sylvia Slade, Ceddie Mason, Reginald Godfrey, Mrs. Hazelhurst, and Mrs. R. C. Pulling; Mr. W. Cole second.

Gloire de Lorraine begonias were grandly staged. Mr. W. Laurance, gardener to E. Clifton-Brown, Esq., was first with profusely-coloured specimens. Carnations in vases were attractive, and Mr. G. West had the best set of three varieties, closely followed by Mr. A. Allan.

Amateurs staged good blooms in the various classes set apart for them. Mr. Stuard Smith was the most successful, securing the N.C.S. Certificate for premier bloom with a richly-coloured Pockett's Crimson, a like honour falling to Mr. Page in the open section for a grandly-developed Evangeline.

Bristol Gardeners' Association.

The fortnightly meeting held at St. John's Parish Rooms, November 9, was presided over by Mr. A. Perry. Mr. J. Ayres gave an interesting as well as instructive paper on "Apple Culture for Profit." He strongly advised preparing the ground well and making the holes large enough so as to be able to spread the roots out at planting time. Mr. Ayres spoke strongly against hard pruning, and did not believe in it because it only encouraged strong growth and brought no fruitful returns. He advocated pruning at first so as to form the foundation of the tree, but after the tree was well established he believed in leaving it alone, except for thinning out branches if crowded. He mentioned a few well-known varieties, such as Allington Pippin, Bramley's Seedling, Ecklinville, James Grieve, Warner's King, and Stirling Castle, and said these were all free croppers. A good discussion followed, and this brought out Mr. Ayres at his best.

For two orchids in bloom (prize given by Messrs. Keeling and Sons), Messrs. Scott and Curtis won in the order given.

Scottish Horticultural.

The November meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 7th inst. Mr. Massie, the president, was in the chair, and there was an attendance of 125 members.

The paper for the evening was by Mr. Wm. Roadley, Comely Bank Nursery, Edinburgh, who took for his subject "Propagation." He first dealt with the propagation of plants by seeds, which was Nature's method, and then took up in detail the various vegetative modes, cutting, buds, grafts, etc. The paper was a most instructive one, and, on the motion of Mr. King, the author received a very cordial vote of thanks.

There were some interesting chrysanthemum exhibits, including some of the newer kinds. Messrs. Dobbie and Co., exhibited Betty Spark, Cranford Yellow, and Miss Collier (decorative) and the single yellows Mrs. T. Gilbey (a yellow Pagram), and Charles Kingsley, for the former of which they received a Certificate of Merit. Various kinds were also shown by Mr. W. Williamson, Edinburgh, and Mr. I. Bruce Davidson's Mains.

As the result of the suggestion made by Mr. Cuthbertson at the conference in October that the members should send in the names of what they considered the best twelve early-flowering chrysanthemums, the following were found to be the favourites: Goacher's Crimson, White Massé, Lillie, Polly, Nina Blick, Abercorn Beauty, Leslie, Elstob Yellow, Hector, Carrie, Diana, and Horace Martin.

Twenty-four new members were elected. At the meeting on December 5, Mr. Thomas Anderson, M.A., B.Sc., Edinburgh and East of Scotland College of Agriculture, will deliver a lecture on "Insects and Flower Pollination" (with lantern illustrations).

FORTHCOMING ENGAGEMENTS.

MONDAY, November 20.—National Chrysanthemum Society; Floral Committee at Essex Hall, 3 p.m.; General Committee at Carr's Restaurant, 7 o'clock.

TUESDAY, November 21.—Royal Horticultural Society; committees meet at 12 o'clock; lecture at 3 p.m. on "The 1912 International Horticultural Exhibition," by Mr. Edward White; Scientific Committee at 4 o'clock.

National Vegetable Society; Annual Meeting at the Horticultural Hall, Westminster, 2.30 p.m.

FRIDAY, November 24.—Aberdeen Chrysanthemum Show; two days.

Hawick Chrysanthemum Show; two days.

WEDNESDAY, November 29.—Irish Gardeners' Association.

National Chrysanthemum Society's Annual Dinner at the Holborn Restaurant.

THURSDAY, November 30.—Royal Horticultural Society's Colonial Fruit Show; three days.

Manchester and North of England Orchid Society.

Erica melanthera.—This is not one of the showiest of greenhouse heaths, but it has made considerable headway in popular favour within the last few years. It is one of the easiest to cultivate, and the peculiar mauve-coloured flowers are borne in great profusion over a lengthened period.—W. T.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

SEEDLING APPLE.—W. A. H., Knowle: The apple sent is very pleasantly flavoured, and would probably have been at its best a month ago, as at present it lacks briskness. In form and colour it is particularly attractive, and there should be a fair demand for the variety in its season. However, it is too much to expect great things from seedling apples nowadays unless they are raised from well-known varieties of the highest class, and thoroughly proved before being placed in commerce. Propagate a few plants by grafting, next spring, and try these in various positions, so as to determine the character of the apple and its suitability for various positions and forms of culture. The apple belongs to the Pippin class, and, hazarding a guess at its parentage, we should suggest its descent from Fearn's Pippin and Worcester Pearmain.

PRIDE OF TENERIFFE. — R. M. K., Bridgwater: Without specimens it is not possible to fully identify the plant, whch you say is known as the Pride of Teneriffe. The photographs do not help us very much as the individual flowers are not clearly portrayed. Judging from the general appearance of the plant, as seen in the photograph, we believe it to be an Echuim, and possibly Echium fastuosum, a perennial evergreen species, with deep blue flowers. We feel pretty sure it is an echium, but are not certain as to the species. Perhaps you can send us a few flowers and a leaf or two of the plant's flower in the coming spring. If you have a few seeds to spare send some to the Director, Royal Gardens, Kew, as a bold greenhouse plant of the character of your plant would not be unwelcome.

PURCHASE OF FERTILISERS.—C. B., Keswick: According to the Fertilisers and Feeding Stuffs Act of 1906, the seller must give the purchaser of a fertiliser an invoice of the article, and state on it the description under which the fertiliser is sold, but also must set forth the minimum percentages of the fertilising constituents of the article sold. We may add that raw bones, bone-meal, or bone-dust should be guaranteed pure, and to contain not less than 45 per cent. of phosphate of lime, and not less than 4 per cent. of ammonia. Boiled bones to be guaranteed pure, and to contain not less than 55 per cent. of phosphate of lime, and not less than 1 per cent. of ammonia. Mine-

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price 10/6. Sole proprietors and manufacturers, Robinson Bros., Ltd., West Bromwich.

PINE SPRAY SYRINGE (patent).

Dr. J. COLLIS BROWNE'S
ORIGINAL AND ONLY GENUINE
Chlorodyne
Universally acknowledged to be the Most Valuable Medicine known, and one which should be in every home.
Acts like a Charm in DIARRHŒA and DYSENTERY.
Cuts short all attacks of SPASMS, HYSTERIA, and PALPITATION.
The only Palliative in NEURALGIA, TOOTHACHE, GOUT, RHEUMATISM.
The Best Remedy known for
COUGHS, COLDS,
ASTHMA, BRONCHITIS.
Refuse imitations and insist on having Dr. J. COLLIS BROWNE'S Chlorodyne.
Convincing Medical Testimony with each bottle.
Of all Chemists, 1/1½, 2/9, 4/6.

ral superphosphate of lime to be guaranteed to contain a certain percentage of soluble phosphate. (From 25 to 28 per cent. of soluble phosphate, is an ordinarily good quality.) Dissolved bones to be guaranteed to be "made from raw bone and acid only," and to be sold as containing stated minimum percentages of soluble phosphate, insoluble phosphates, and ammonia.

DESTRUCTION OF STINGING NETTLES.—M. E. M., Kettering: Where the common stinging nettle (Urtica dioica) is a plague, and cannot be dealt with by the ordinary garden method of digging and forking it out, followed by close cropping and good cultivation, it may be overcome by regular cutting from the time the shoots appear in the spring, cutting taking place each time the fresh shoots attain 6in. to 1ft. in height. This plan, thoroughly and regularly carried out, exhausts the reserves of food material stored up in the root-stocks, and eventually kills the weed. The eradication will be materially hastened by a dressing of salt (at the rate of 5½lb. per rod, or 6 or 7 cwt. per acre) when the nettles are first cut in spring. Experiments conducted in Germany in 1909 with a view of destroying nettles on large areas, showed that the young shoots were destroyed in spring by spraying with a 15 per cent. solution of kainit, applied with an ordinary charlock sprayer. The shoots became black and died off, and the grasses won the mastery, so that at the time of hay harvest the area seemed quite free from the pest. Careful examination showed that the fresh delicate shoots from the root-stock appeared sickly and but little grown, while the root-stocks themselves were black and had begun to die. (As about 35 per cent. of kainit consists of common salt, it is probable that the effect of spraying with the solution of kainit is largely due to the salt contained therein.)

BILBERRIES AND HUCKLEBERRIES.—C. S. W., Launceston: The Rose order contains a large number of "berries," notably the raspberry, strawberry, blackberry, and loganberry, with the newer additions, but probably the genus Vaccineum includes more "berry" plants than any other. Vaccinium arboreum, is the fackleberry; V. macrocarpon (more correctly Oxycoccus macrocarpus), is the American cranberry, and V. Oxycoccus (Oxycoccus palustris) is the common cranberry; V. myrtillus, the bilberry or common whortleberry; V. stamineum, the deerberry or huckleberry; and V. vitis-idaea, the cowberry. All these plants love moist, peaty soil, such as a bog so often affords.

FORESTRY.—W. J. M., Cardiff: A handy and useful book on the subject is "Webster's Practical Forestry" (W. Rider and Son, Bartholomew's Close, London, E.C.)

CATTLEYA CITRINA.—W. S. O., Lydd: This fragrant species is usually best managed when grown upon a wood block, head downwards, with a moderate mound of peat or osmunda fibre and sphagnum fixed about its roots. It thrives in a cooler atmosphere than is desirable for most cattleyas, hence the coolest end of the cattleya house, or the warmest end of the odontoglossum house will suit it. We have seen C. citrina grown in pots and pans, and its flowers staked rigidly upright, but they look very unhappy under these conditions, as the flowers are pendulous and not meant to stand erect. We are glad you find so much help and guidance in the Orchid Notes under "Work for the Week."

PROPAGATION OF PHYSALIS. — R. B. B., Twyford: Both Physalis Alkekeagi and P. Franchetti are easily propagated from seeds sown in cold frames as soon as ripe, in the autumn or early winter. Seeds may also be sown and plants raised out of doors in spring. Another common method of propagation is by division of the roots in late autumn. The tops of the young growths removed in early summer, and inserted as cuttings, will root readily in sandy soil in a cool and shaded position.

NAMES OF PLANTS

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

B. F., Erith.—1, Vitis heterophylla; 2, Arbutus Unedo; 3, Nephrolepsis Duffi; 4, Viburnum tinus.

H. G. L., Wolverhampton.—1, Calanthe vestita oculata; 2, Adiantum capillus veneris Mariesi; 3, Acrostichum crinitum.

C. R.—1, A garden form of Nephrolepis exaltata; 2, Asplenium bulbiflorum; 3, Episcia chontalensis; 4, Maranta Veitchi.

E. T. J., Wrexham.—1, Brassia verrucosa; 2, Epidendrum variegatum; 3, Cypripedium Arthurianum; 4, Odontoglossum Wilckeanum.

R. H. A., Slough.—1, Physalis Franchetti; 2, a leaf of a Heuchera, probably H. sanguinea; 3, Cattleya labiata; 4, a good form of Cypripedium insigne.

B. G. R., Hants.—1, Escallonia macrantha; 2, probably Azara microphylla; 3, Cotoneaster frigida; 4, Pernettya mucronata.

N. G., Effingham.—Clerodendron trichotomum.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

G. S. W., Burton.—1, Bramley's Seedling; 2, Yorkshire Beauty; 3, Golden Spire.

A. S., Jersey.—1, Lane's Prince Albert; 2, Ferne's Pippin; 3, Uvedale's St. Germain.

H. A., Taunton.—1, Court of Wick; 2, not recognised; 2, Mère de Ménage; 3, Hollandbury; 4, New Hawthornden.

F. P. V., Worksop.—1, King of the Pippins; 2, Golden Noble; 3, Blenheim Pippin; 4, Dutch Mignonne; 5, probably Gravenstein.

A. S. C., St. Neots.—1, Claygate Pearmain; 2, Dumelow's Seedling; 3, Grenadier; 4, Lady Henniker; 5, Bismarck; 6, Waltham Abbey Seedling.

NOTE OF THE WEEK.

◆

The Life of a Leaf.

When we look at a large tree, say one of those wide-spreading deciduous oaks, such as we see in spacious parks where the individual tree is entirely free from competition with its fellows, and extends its huge dome-like crown and wide-spreading branches upwards and outwards in untrammelled beauty, we are always inclined to regard its leaves as mere appendages of secondary importance which derive their support from the great root system underground, instead of being, as they are, the all-essential builders of the entire fabric. We may, indeed, liken these leaves to the individuals of a great community, each one with a life of its own and duties to perform, which consist, as with those of human individuals, in gathering material from their environment, and working this up, not only for their own support, but also as a contributor to the construction, maintenance, and extension of a great ramifying system of thoroughfares and channels akin in function to those of a great city. Each leaf we may consider as having been born within a bud, which represents the offspring of its progenitor, the leaf of the previous season, since it is the province of the leaf in the late summer to devote part of the material at its command to fashion at its base, where its stalk is attached to the sustaining twig, the bud in question, so that when its individual life ceases, it may leave a successor, ready when the growing season recurs, and the warm sun and genial showers of April exercise their revivifying influence, to wake up, or rather to be born, like its parental leaf, for another career on like lines. Not only, however, has this parent leaf provided thus for its immediate offspring, but during all its career it has been busily absorbing, from the air around it, the carbonic acid gas therein present in a very small proportion. By its own vigorous cell-growth it has also set up a drain upon the root system far below by absorbing water from cell to cell as they grow and multiply, and thus, through a continuous chain of other cells in twig, branch, and trunk, transmitting this absorptive pressure right down to the roots. This done, by transpiring what they do not need into the air, there is thus induced a constant upward stream of sap which is the life-blood of the community. The roots, however, are by no means the source of the perfected life-blood or sap, but only collectors and contributors of part of its materials, viz., the all-esential water and such earthy salts as may be soluble therein, and thus transmitted in solution to the leaves above. It is the living leaf, which, utilising this solution and uniting it in innumerable combinations with the carbon extracted from the aerial gas, while completing its own marvellous structure of supporting veins and cellular growth, digest, as it were, this mixture, and by a sort of reflex current returns it as perfected sap or life-blood proper, to build up, not only its own particular twig and associated leaves in the immediate vicinity, but also to send its contribution to strengthening the general fabric by enveloping the trunk and secondary branches and twigs with the annual ring of new wood. It also provides for an independent generation of the tree itself by contributing to the formation, first of the flowers and then of the precious seed, which are entirely dependent upon leaf industry exercised under the beneficent influence and stimulus of the sunbeam. By the autumn all this wonderful work is completed, and the leaf, having finished its task, and prepared, as we have described, for its successor, has but one more duty to perform. We have chosen a deciduous example rather than an evergreen as better typical of the majority, though evergreens in the long run pass through similar phases. In the leaf-shedding tree, then, we see the leaf, its duty done, begin to prepare for a sacrifice. The winter is a period of storm and stress, and also it may be of intolerable burdens of snow, or even of ice, and to retain its panoply of leaves would, to many trees, lead to terrible damage by breakage, even if not to the utter destruction by overthrow. Bare and leafless branches minimise this risk to the utmost, and therefore the last office of the dying leaf is to sever its connection spontaneously by disjunction of its connecting cells at a point near the bud. If we pick up a shed leaf at this period of fall we may see clearly that the stalk terminates in a clean surface, and not a ragged or broken one, such as would be shown earlier in the season if it were broken off. The marvel of marvels in the living leaf has yet to be indicated, and that is the chlorophyll, the green colouring matter, which pervades its tissues in the form of tiny grains. It is these grains alone, of all thing in the world, which are gifted with the power of absorbing the vital energy of the sunbeam and responding to its stimulus in such a way as to seize upon the inorganic materials, the earthy salts, and aerial gas, and work them up into these forms of vegetable nutrition upon which all animal life depends, including, of course, our own, while at the same time building up the great bulk of other materials which form the basis of all progress, commercial or otherwise, in one way or another. Without chlorophyll, the sun would shine upon a

MR. A. GAUT.

barren desert; but with it enshrined in the wondrous fabric of the leaf, no words can even faintly picture the beauty and multiformity of its direct and indirect creations and the marvels they embrace.

Mr. Alfred Gaut, whose portrait we have the pleasure of giving herewith, has specially distinguished himself in the furtherance of an extended knowledge of horticultural matters in Yorkshire, and is held in high estimation by all classes of the community in the county who are interested in gardening. Mr. Gaut, who occupies an important position in connection with the Leeds University, has achieved a high degree of success as a county lecturer on horticultural matters, and this success is due to his thorough practical knowledge of all that relates to gardening, and his marked ability in conveying his knowledge to others. Mr. Gaut had the advantage of being trained in such gardens as those of Elvedon Hall, Suffolk; Sherborne Park, Gloucestershire; and two of the leading nurseries in London. Also of having occupied the position of head gardener at Riddlesworth Hall, Norfolk, and Berwick House, Shropshire; and of being head gardener and bailiff at Porter's Park, Shenley. Thus equipped, Mr. Gaut entered on his duties of lecturer in horticulture to the Shropshire County Council, and did excellent work during the two years over which his occupancy of the post extended. He was then appointed to the more important position at the Leeds University, which he has filled with so much success for a period of nearly eleven years. Mr. Gaut's work is chiefly in connection with the county lectures, which are very successful, whether given to artisans and colliers or to the members of the community engaged in agricultural work. Allotments have increased enormously in many parts of Yorkshire during the past ten years, and this increase is attributed by those well qualified to express an opinion upon the subject to the efforts of the three County Councils to provide efficient teaching by means of lectures and demonstrations, and the appreciation of these efforts by the people at large. Mr. Gaut has from the first taken a keen interest in the activities of horticulturists in and around Leeds, whether for the advancement of gardening or the improvement of the position of gardeners. He has written a book on seaside planting, which was published by Messrs. Newnes a few years since, and was described in these pages as the best book on the subject that had been published; and the opinion then expressed holds good at the present time.

Illness of Mr. E. Mawley, V.M.H.—The friends of the genial and exceptionally able hon. secretary of the National Rose Society will deeply regret to learn that his health has been such as to render it necessary that he should undergo a somewhat serious operation. They will, however, be glad to know that the operation has proved successful, and that the progress in his recovery is proceeding so satisfactorily as to fully justify the anticipation that he will in a very short period be completely restored to health.

Royal International Horticultural Exhibition, 1912.—With reference to the regulations for exhibitors at this great gathering, the directors desire to draw the attention of exhibitors to the fact that they have decided not to enforce the condition printed at the foot of the entry forms already distributed in the schedules, to the effect that specimens (plants, etc.) must have been cultivated by the exhibitor for at least two months prior to the date of the show. Regulation 20 in the revised schedule is the only stipulation of the kind that will be retained—namely, that the "exhibits must be the property of the exhibitor, or of the employer in whose name they are shown." The directors also announce that they will provide all necessary plates and vases; the plates will be of cardboard or papier machê. At the afternoon meeting of the Royal Horticultural Society on Tuesday last. Mr. E. White, the hon. director, read a highly-interesting paper on the forthcoming exhibition, to which we shall take an early opportunity of referring. It was gratifying to hear from Mr. White that there is every prospect of the gathering proving in all its details an unqualified success.

Protection for Wild Plants.—At their meeting held on the 15th inst. the Kent County Council adopted a bye-law prohibiting the uprooting or destruction of any ferns or other wild plants growing in any road, lane, roadside waste, wayside bank, hedge, common, or other public place in such quantities as to cause damage or disfigurement. This bye-law has not been adopted any too soon in Kent, and we trust that it will be rigidly enforced.

Jubilee of the Southampton Horticultural Society.—A special meeting was held on the 7th inst. to consider the question of celebrating this society's jubilee next year. In the unavoidable absence of the president, Lord Swaythling, Mr. A. J. Day, J.P., the senior vice-president, took the chair, and Mrs. Day, daughter of the late General Lacy, the founder of the society, was also present. Mr. E. K. Toogood, chairman of the council, submitted the programme suggested by the council—viz., a rose show on June 26 under the auspices of the National Rose Society, which had accepted an invitation to hold a special early provincial show at Southampton, the desire of the promoters being to make this the best exhibition of early roses ever held in the South of England. It is also proposed to hold a grand jubilee show and gala during the third week in July, probably the 16th or 17th, comprising the usual Carnation and Sweet Pea Show, together with fruit, miscellaneous plants, flowers, vegetables, etc. The Autumn Show to be held as usual on November 5 and 6. Mr. Toogood pointed out that to conduct these shows on a scale worthy of the society's traditions a considerable sum would be necessary beyond the usual subscriptions, so it was proposed to open a special prize subscription list, which he hoped would receive a ready response. Promises of special prizes and donations, including a 15-guinea challenge trophy for a display of roses, from the Hon. Mrs. York; and five guineas from the President, were handed in, the total amount being £40.

Culinary and Dessert Apples for Cider.—In the report issued by the National Fruit and Cider Institute it is pointed out that culinary and dessert varieties of apples are usually considered of little value for cider making, but it is suggested more attention should be given to their use, as a means of utilising small fruit. A number of market varieties grown in the institute plantations have been analysed, and small-scale tests made to ascertain the type of cider produced. From the results it is seen that with very few exceptions the juice is poor in sugar and tannin, while the acidity is high. In the report it is stated that it is clear that the use of market fruit alone for cider making in the usual way can only be extremely limited as regards the type of cider produced. The kind of beverage produced by ordinary methods will be a thin, dry cider, lacking in body and of marked acidity, probably possessing poor keeping qualities. This has proved to be the case in the few instances where tests on a practical scale have been made at the institute in past seasons. These tests have, however, shown that it is practicable by suitable treatment to produce a palatable and marketable beverage, even although it may not bear comparison with a cider made from true vintage fruit. There has been nothing in the flavour of these ciders to constitute any serious drawback, and, indeed, in one instance, it was so good that a really delicate dry cider was produced by suitable blending. There appears to be two directions in which satisfactory results may be expected. The first consists in the utilisation of a moderate quantity of true vintage fruit of the sweet and bitter-sweet types to blend with the market sorts. The other course of procedure is to increase the original amount of saccharine matter in the juice by the addition of sugar in such quantity that when completely fermented the liquor will contain sufficient alcohol to restrain acetification.

Edinburgh Chrysanthemum Show, of which a full report appears in another part of this issue was, we are pleased to learn, more largely attended than for several years past, notwithstanding the somewhat unpleasant climatic conditions that obtained during a part of the period over which the exhibition extended. On the opening day there were 4,638 visitors, against 3,855 on the corresponding day of last year, and on the second day the visitors numbered 6,097.

The Northern Fruit Congress.—Owing to the great pressure upon our space this week, we are holding over our report of the Congress on Fruit Culture and Educational Matters, held at Newcastle last week, until our next issue. We do this because we should have had to severely curtail our reports of exhibitions and meetings, and of the Congress itself, to get them into the present issue, and thereby reduce their interest and usefulness.

Manuring of Meadow Land.—For some years past experiments in the manuring of meadow land have been carried out by Mr. E. Parke and Dr. Bernard Dyer upon the farm belonging to the former at Kineton, Warwickshire, and highly instructive results have been obtained. The report on the experiments during the past spring and summer have been published, and contains much to interest those who have charge of grass land. The effect of the manurial dressings in mitigating the influences of the drought is especially interesting. Fertilisers applied in dry weather are retarded in their action, and may be rendered ineffective for the current season, but the dressings at Kineton were distributed before the dry weather set in, and it is instructive to learn from the report that they were more than usually instrumental in promoting the growth of grass. The average yields from the unmanured plots in the two fields were only 7 cwt. and 8 cwt. of hay per acre respectively. The report states that these quantities were more than doubled by 3 cwt. superphosphate per acre in one field and by 5 cwt. basic slag in the other. A dressing of 1½ cwt. nitrate of soda per acre in addition trebled the yield. The difference in the composition of the herbage is equally pronounced. Whereas the unmanured land is full of weeds and undesirable grasses, there is a rich turf on all the manured plots, with clovers abounding where the mineral manures were applied. The plots receiving both phosphates and nitrate, which yield 50 per cent. more increase than when either of the fertilisers is used singly, are also rich in clovers as well as in true grasses.

Elliottia racemosa.—A note on this interesting and extremely rare shrub appeared in the "Kew Bulletin," 1906 (p. 226). At that time it was not possible to say anything as to its beauty from direct evidence, as the two plants at Kew (which are believed to be the only ones in Europe) had neither of them flowered. The larger plant of the two, now about seven feet high, has, according to a note in the current issue of this publication, borne during the past summer 21 racemes, the first flowers opening on July 24. It proves to be a shrub of great beauty as well as interest and rarity. The racemes are terminal, quite erect, 6 to 9 inches high, 2 to 2½ inches in diameter, the flowers mostly solitary, occasionally in pairs or in threes on the peduncle. The flowers are pure white, fragrant, and from three-quarters to one inch across. The flower-bud is at first erect on the peduncle; as the flowering time approaches it becomes inverted and nodding; but just before the expansion of the petals it rises again and stands out horizontally; and in that position the flower remains. A raceme six inches long bears about 40 flowers. Elliottia is a monotypic genus, and flowering as it does towards the end of July, it would make a delightful addition to flowering shrubs could it become common in gardens. But it is almost or quite extinct in its native localities in Georgia, and no successful method of propagating it has yet been devised. Cuttings of the branchlets have several times been tried at Kew without success. The only plants raised have been two from root cuttings, but both ultimately died. The fruit of Elliottia is not known, and it is unfortunate that, although artificial fertilisation has been resorted to no fruit has been obtained. Bees have also visited the flowers in great numbers.

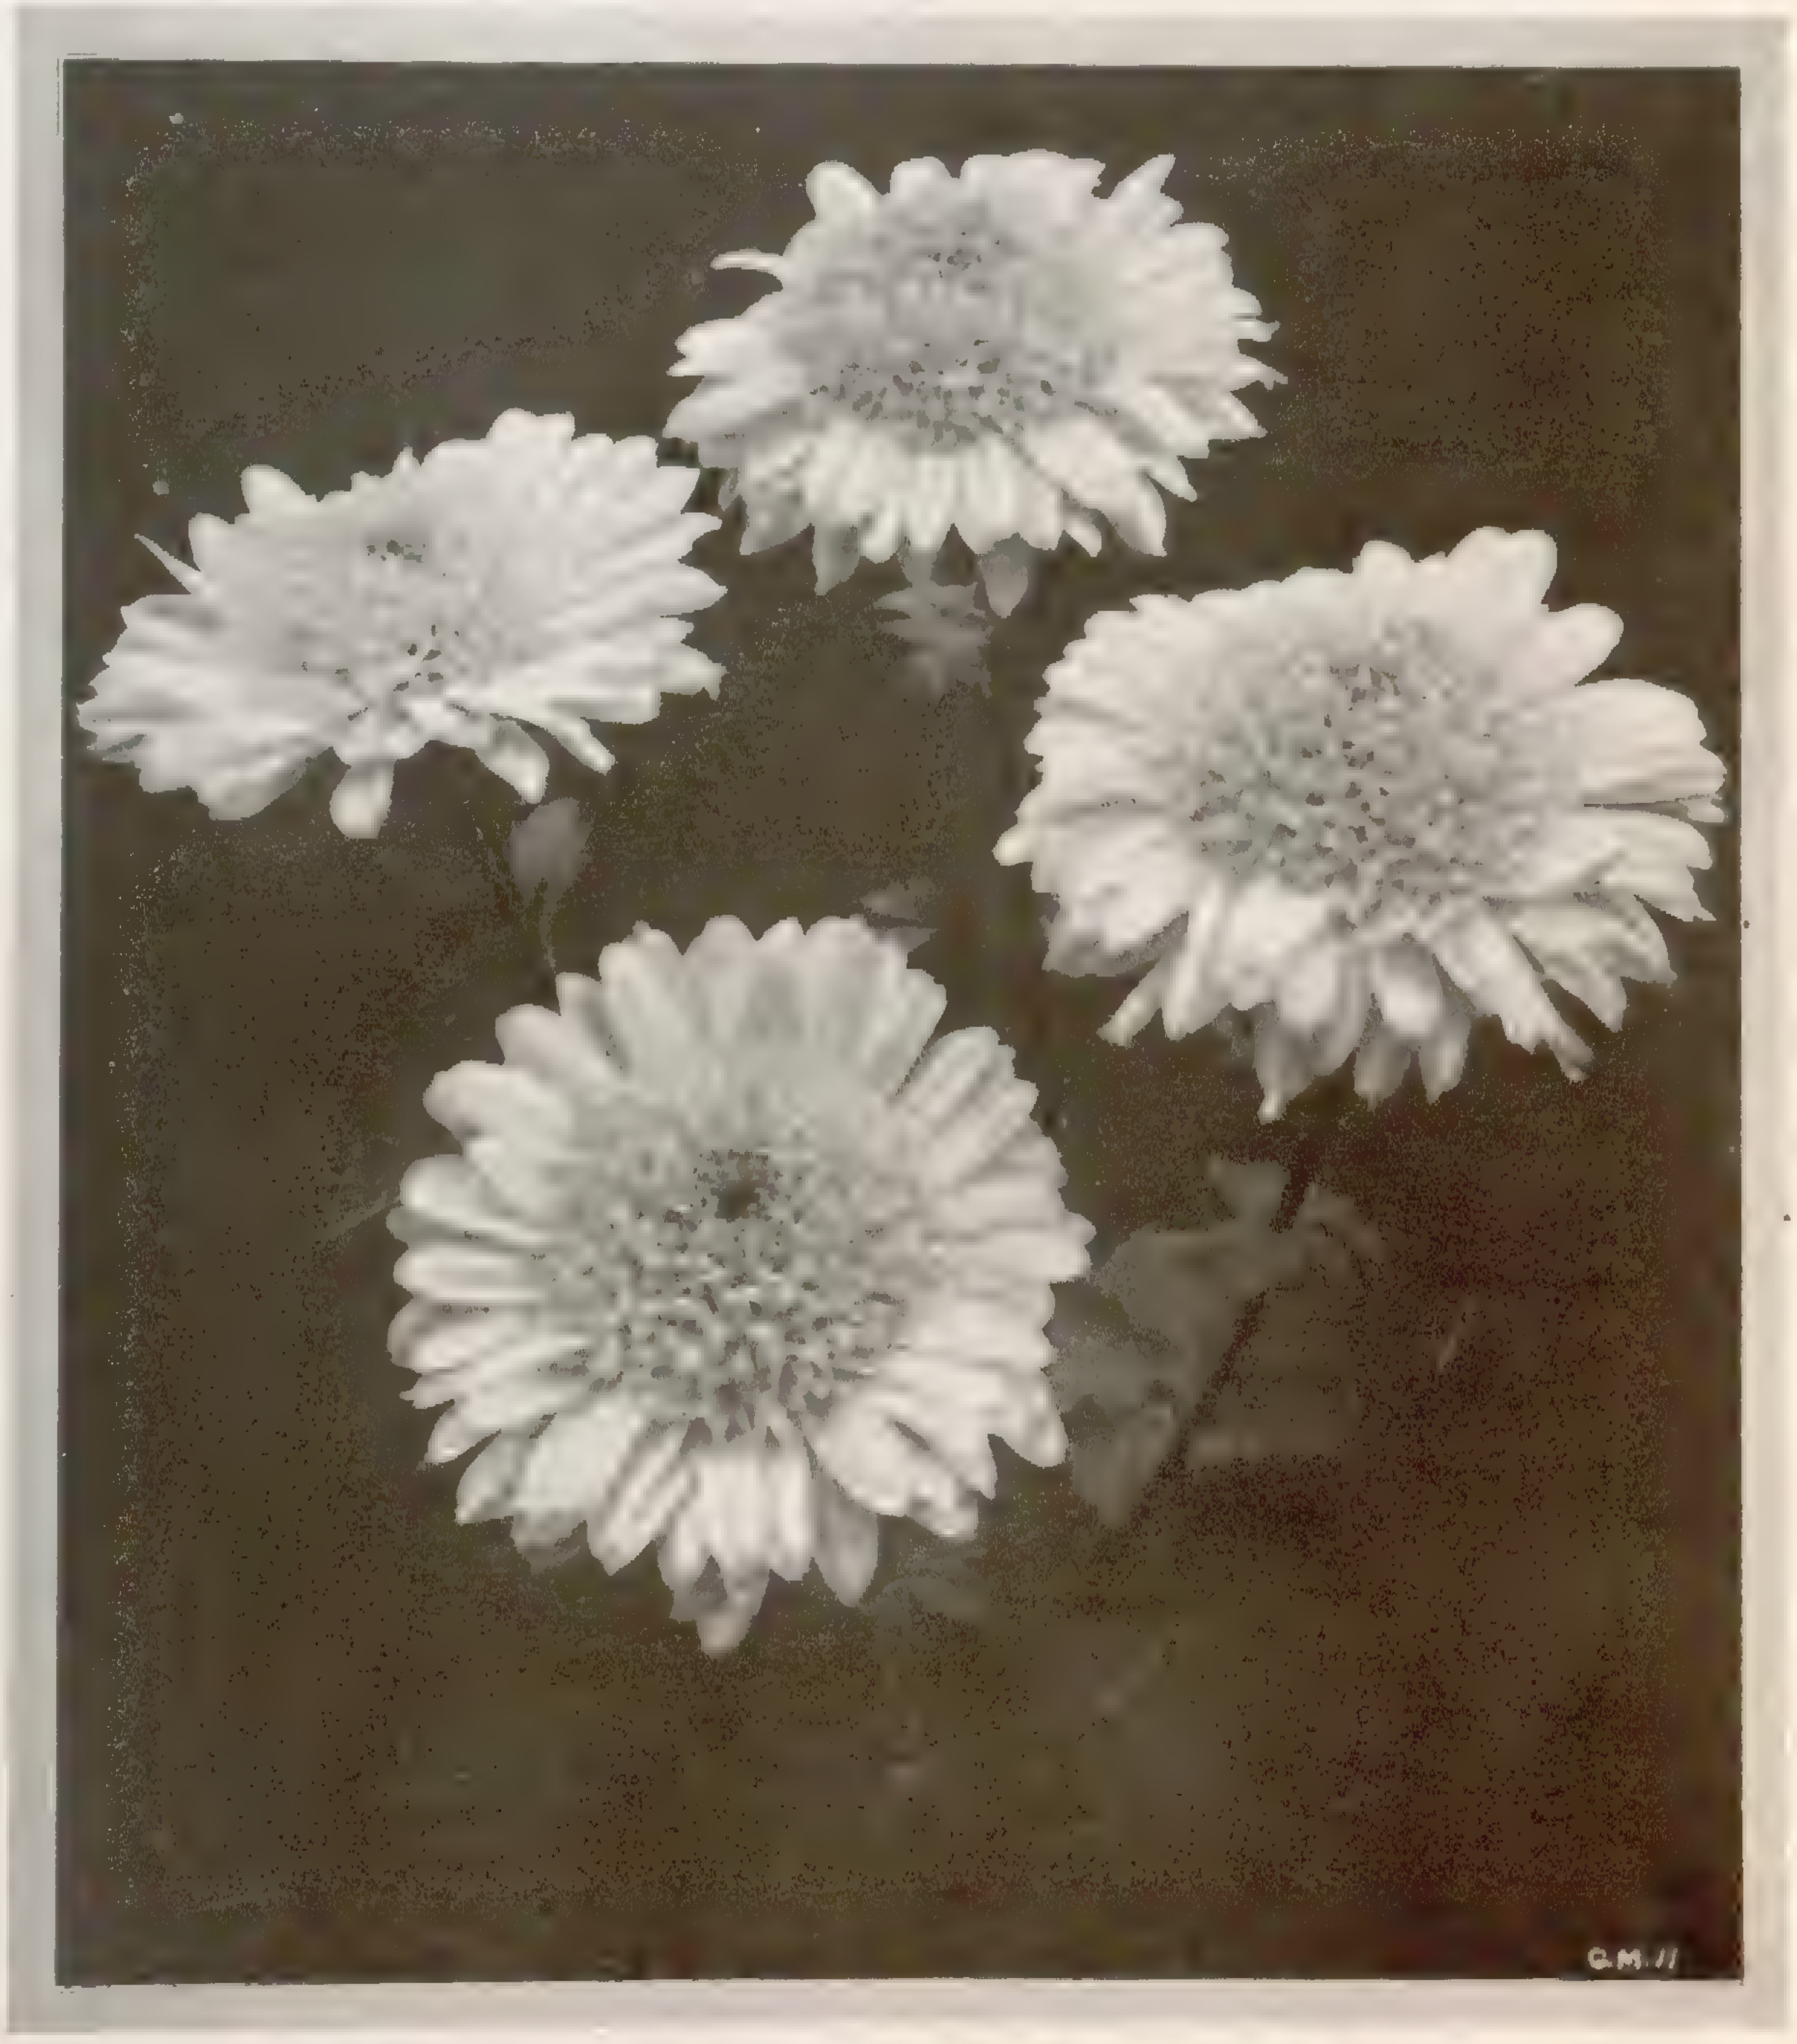
The Ancient Society of York Florists may be congratulated on the highly successful show that was held in the Exhibition Buildings on the 14th and 15th inst. The show was considered one of the best the society has held, and the attendance was above the average. Mr. F. Styan, York, obtained premier honours in the class for a pillar group with an effective arrangement. Mr. Spencer, of Harrogate, was first for a group of miscellaneous plants; and Mr. W. Hields, Acomb, first for a group of chrysanthemums. Cut blooms were especially good, and the more successful of the winning collections came from the gardens of Duncombe Park, Londesborough Park, and Sand Hutton. The question of holding the North of England Fruit Congress at York next year, in conjunction with the Chrysanthemum Show, is under consideration; and, as the proposal has been favourably received, it is anticipated that arrangements will be made for holding this important gathering in the city in 1912.

Women's Agricultural and Horticultural International Union.—The annual meeting of the women horticulturists was held on the 15th inst. in the famous Indian Museum at the residence of the Earl and Countess Brassey, in Park Lane, W. There was a large attendance at the meeting, which was presided over by Lady Willingdon, who spoke in a most complimentary manner of the work carried out by the Union. The report of the year's work was read by the secretary and treasurer, and the first three diplomas in practical horticulture were presented. An interesting address on "Hybridisation" was given by Professor Bottomley, of King's College. Two important changes were announced for next year—the removal of the offices to Westminster in January, and the transference of the summer show from Regent's Park to the Royal Horticultural Hall, the date being October 23.

Award to Messrs. G. Bunyard and Co.—To the exhibition of the Coventry Chrysanthemum Society Messrs. George Bunyard and Co., of Maidstone, contributed a collection of one hundred dishes of hardy fruits, representing as many distinct varieties. The whole of the fruit was remarkable for its high quality, and the collection was admirably staged. The exhibit, indeed, was of so high a degree of excellence that it was highly attractive, and the committee awarded the firm a large gold medal.

Sandgate Arbor Day.—At a meeting of the Sandgate Society held at Enbrook, by invitation of Lady Chichester, Mr. Mark H. Judge in the chair, it was decided that the first celebration of Arbor Day in Sandgate should take place on Saturday, December 2. Arrangements were made for a lecture on "The Origin and Use of Arbor Day," by Mr. E. D. Till, of Eynsford, and this was given on Wednesday, November 22.

Proposed Research Institution for Fruit Growing.—A meeting of the Governors of the South-Eastern Agricultural College, Wye, was held at Caxton Hall on Monday, November 6, Lord Ashcombe presiding. The principal, Mr. M. J. R. Dunstan, reported that the entry of new students, 56, the number attending the college, 141, and the number from the contributing counties, 70, were the highest yet recorded. It was decided to approach the Board of Agriculture and the Development Commissioners with regard to the foundation of a Research Institution for Fruit Growing, including the practical treatment of plant diseases, in the county of Kent; and also to apply for a grant in aid of the proposed extension of the college buildings. The following resolution was proposed by the chairman of the Surrey County Council, Mr. A. W. Chapman, and seconded by the chairman of the Kent County Council, Mr. F. S. W. Cornwallis: "That, in view of the discussions that have recently taken place in connection with the management of Wye College, the Governors think it desirable to place on record the fact that nothing whatever has occurred to induce them to withdraw the complete confidence they have always reposed in Mr. Dunstan, the principal of the college, to whose energy and ability the continued progress of the college is largely due."



CHRYSANTHEMUM GODFREY'S PERFECTION.
A pure white anemone-flowered variety. A.M., R.H.S., November 21.
Mr. J. W. Godfrey, Exmouth.

Early-flowering Chrysanthemums.—An instructive lecture, illustrated by lantern slides, was given by Mr. J. Steer at the monthly meeting of the Brighton Horticultural Society, held on the 16th inst. In the course of the discussion at the close of the lecture Mr. J. Gaston stated that 107 new members had joined the society during the year, and it need hardly be said this statement evoked considerable applause.

CHOICE OF THE BEST VARIETIES OF APPLES.

On page 836 of your issue of November 11 "Practical Fruit Grower" has done all fruit growers a good turn, and I, for one, desire to thank him. Many nurserymen would only be too glad to limit the varieties of apples, but the public generally, and often so-called experts, have not yet been taught that for ordinary utilitarian purposes there must be an end to the happy-go-lucky indiscriminate planting of all sorts of apples.

There are three distinct views of apple culture. 1. There is the exhibitor's. Like his brother poultry exhibitor, he does a great deal of harm to the utilitarian man, for what looks well on the exhibition table, e.g., a Cox's Pomona, a Peasgood's Nonsuch or an Emperor Alexander, is just what the ordinary person with an ordinary garden should not grow. I would bar Peasgood—except for wall culture only.

2. Then there is another class—the big amateur. Naturally, his gardener has to provide supplies all the apple season through, and he also has a proper storeroom to keep his apples in. The cook has to be appeased; showy fruit is required for the table, and dessert apples all the season through are asked for by Master George and Miss Marjery!

3. But when we come to the mass of apple growers—the market grower, the cottager, and the smaller amateur—then it is that we see the reason to be grateful to "Practical Fruit Grower" for his article on the best apples in their season, and according to class.

Taking the apples named one by one, I would like to say a few words, as far as the matter concerns the North of England, with which I have now a fair acquaintance. Early Victoria, Grenadier, Lane's Prince Albert, Bramley's Seedling, and Newton Wonder. I agree word for word with the remarks on all the above five apples, with this one difference, that I would plant Bramley alone on both stocks—the broad-leaved paradise and the crab—the paradise stock to give me the fruits, the crab for my children. As far as my knowledge and experience goes, Bramley is the one safe apple to plant as a standard in the North, for, apart from other considerations, it "hangs" well, and withstands our western gales successfully.

Stirling Castle is certainly above all others "the poor man's apple," and, as stated, only requires food and attention to remain healthy. But why is it that this elementary fact is so often overlooked? We feed our potatoes and our cabbages, but, as for our fruit trees, we "howk a hole, shove them in, and stamp on them." All fruit trees need feeding and attention, and especially do bush apple trees on the Paradise stock require feeding regularly, but carefully, when the fruit is set. As regards Norfolk Beauty it is little grown up here yet, Warner's King reigning supreme. I would certainly recommend Bismarck before Blenheim Pippin, and dispense with Lord Derby or Tower of Glamis as bush trees.

As regards the dessert section, I would simply say that of those recommended I can heartily agree with Mr. Gladstone, Beauty of Bath (when it commences to bear), Lady Sudeley, Worcester Pearmain, James Grieve, and Cox's Orange (when planted near some strong pollen bearer, such as Bramley's, or the hybrid crabs).

I would lift Allington Pippin out of obscurity, rejecting Ribston. Wyken Pippin certainly does well in several places in the North. To my knowledge, there are some grand standards of the variety bearing prolific crops year after year. Sturmer Pippin bears well, but seldom ripens properly. In conclusion, I may say that a market grower friend of mine would go one better than the grower mentioned, and limit his varieties to two—Lord Grosvenor and Lane's Prince Albert.

I think, however, that when he has given Early Victoria a trial, Lord Grosvenor will have to give place to this free-bearing healthy variety, less wasteful, too, in cooking.

J. Bernard Hall.

THOUGHTS ABOUT THINGS.

"But what a wonderful season it has been!" This is the frank admission of everybody just now, when the experiences of the year are under discussion, and it generally winds up a conversation in which one gardener has been recounting to another some of the difficulties with which he has had to contend. The sands are quickly running out; in a few weeks' time the wonderful year of 1911 will be gathered to its fathers, but, speaking climatically, it has made history. We need talk no more about old-fashioned summers, when the very latest has beaten all known records for heat and sunshine, and, probably, when the men who are now young have grown old they will rake up experiences of that Coronation year, and its wonderful summer, with all that display of pride which veterans assume when recounting the happenings of the past.

Could it be possible for such a year to come and go without teaching its lessons and without bringing with it experiences of a unique character? I think not, and we have before us, fresh in the memory, 1910—dull, wet, gloomy, and sunless, followed by 1911—hot, bright, sunny, and dry. Both, of course, have had their drawbacks, but which, from the gardener's point of view, would you prefer, supposing you had the ordering of the seasons, and had only the two examples to select from? Different people might give different answers to this question, but I put it to a market gardener the other day, who cultivates deeply, and does not think fifty tons of dung to the acre a too heavy dressing for some of his crops. "We haven't had as much stuff as usual," was his reply, "but we've been able to sell it, and mustn't grumble." There you have it, for it is the good cultivator who has come out on the top this year, just as he always does in a trying season, because his liberally manured land has yielded its increase, and he has reaped the benefit of the good prices which have prevailed.

1911 will be remembered as the year in which Nature provided us with a good apple crop, and painted such colours on the cheeks of the fruit, the like of which few of us have seen before; but are the apples going to keep well? There is a general impression that they will not, and, if not, why not? This is one of the various problems of the year, and one would have thought, after such a summer of warmth and sunshine, that apples would have kept perfectly. Such, however, does not appear to be the case, and it would be interesting if we could get some scientific opinion as to the reason why. The matter-of-fact practical man expresses the view that the fruit ripened too quickly, and, whether he is right or wrong, the fact remains that many growers are pushing their late apples into the market, not so much as a matter of choice, but because of fears that the fruit will not keep. This is the reason why, at the moment of writing, apples are plentiful, and growers are complaining about low prices; but, in all probability, history will repeat itself, and, despite good crops, home-grown apples will be scarce enough a month or two hence.

Speaking of apples, there never was a season when all varieties cropped alike, and it is quite as well that this should be so, but 1911 will be remembered as a year in which certain apples bore remarkably well. As a case in point, let us take Cox's Orange Pippin, which, in a general way, is not the most certain of croppers, but few people have any complaints to make about it this time, and samples generally are good. Indeed, I have seen specimens of this popular variety so fine at shows this year that some people expressed the doubt as to whether they were Cox's at all. Newton Wonder is another apple that has triumphed this year, and it has put itself quite in the front rank of long-keeping varieties. During recent years thousands of trees of this variety have been planted for commercial purposes, though some have described it as a shy bearer, but its behaviour this year has contradicted any such assertions, and Newton Wonder is amongst the leading apples of the season. How well, too, has our old friend Lane's Prince Albert done, and, the other day, I saw a specimen which turned the scale at twenty ounces!

H.

PINUS BUNGEANA.

The lace-bark pine of China is one of the most remarkable and attractive of its kind. It is still amongst the rarest of pines in gardens, but is represented at Kew by a number of well-grown examples. These have produced cones in recent years, and the species has been figured in the "Botanical Magazine" t. 8240. No cultivated specimen appears yet to have developed the white bark which is the most remarkable characteristic of this pine, and which is well illustrated in the plate in "Kew Bulletin" of trees growing in the environs of Peking. The Kew trees shed their bark freely after the fashion of a plane, but the newer bark revealed is dark brown and not white. The accompanying extract from an interesting letter of Sir Edward Satow's would seem to show that this is probably due to the comparative juvenility of our trees:—

"Here is a photograph of three specimens of Pinus Bungeana standing about three miles west of Peking. The structure on the left of the centre tree is an old tomb, and the height of the masonry as far as my recollection goes is about 8 feet, which affords a standard for measuring the height of the trunk up to the point where the branches begin. The tomb is quite old, and neglected, so that possibly it is more than a century old. There are a great many of these trees in and near Peking, either in the grounds of palaces or planted in private graveyards of wealthy families. I never saw one that seemed self-sown. I find a note made in 1904 that sometimes the trunk divides a few feet from the ground, and the stems grow up straight side by side. In other cases it reaches a height of at least 20 feet without dividing, and then branches out, forming almost a spherical head. The younger trees have a greenish reddish bark, which in older specimens looks quite white when seen from a distance. The peasants scratch the bark with a knife in order to procure the resin.

"When I planted one in the grounds of the Legation I was told by the Chinese florist from whom I bought it, that these trees do not exhibit a white bark till they are about fifty years ago."—"Kew Bulletin."

PLANTAIN LILIES.

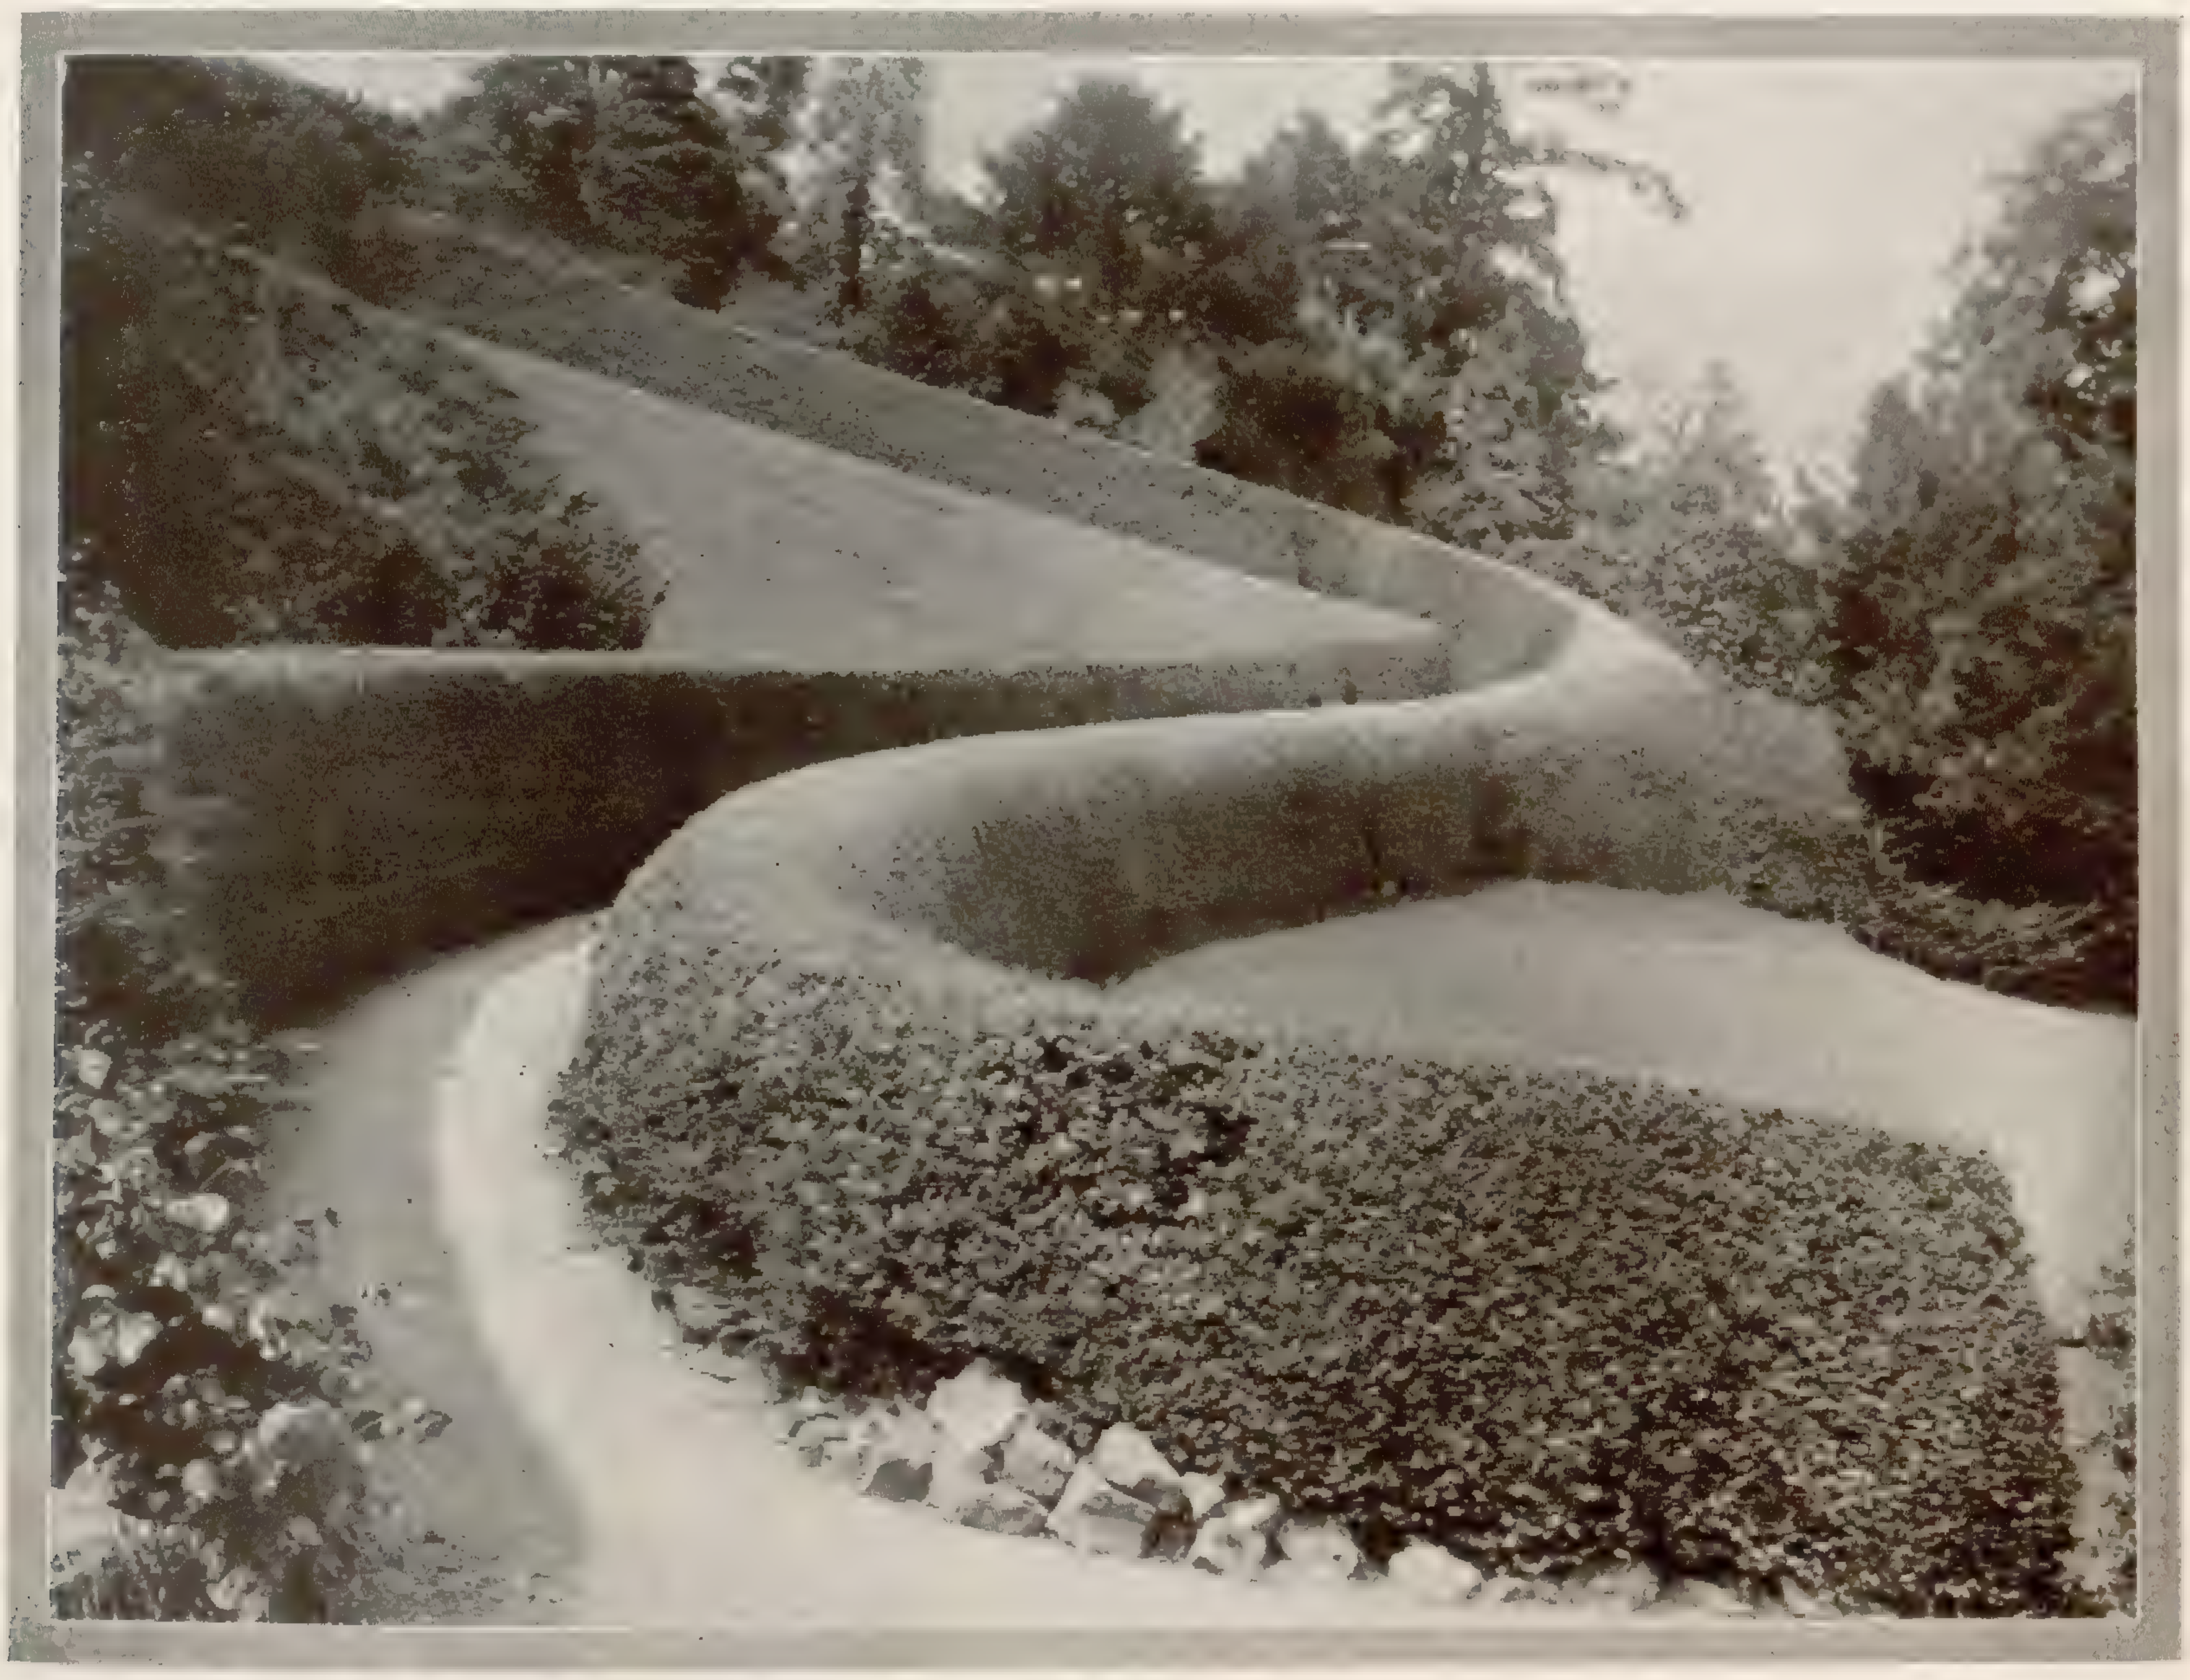
Shady beds and borders are generally rather difficult to render attractive in the summer time, for though spring-flowering plants will do as well in such positions as anywhere, e.g., doronicums, dielytra, myosotis, Solomon's seal, scillas, the primrose family, etc., the number of summer-flowering plants that will thrive where they get little or no sun is decidedly limited. Funkias form one of the few groups that prefer much shade, doing well even where in June they only get the sun in the early morning or evening, their foliage sometimes developing to a great size under such conditions, if there is sufficient moisture, whereas if grown in full sun their flowering spikes are often dried up during the first two or three hot days in June. Their main requirement is a deep, well-cultivated soil, inclined to dampness, and though some of the larger-leaved sorts are suitable for growing in groups by the waterside, most of them will not do well where there is stagnant moisture. They develop their handsome foliage early in the spring, and keep green till the autumn, throwing up their spikes of bell-shaped flowers, usually of a lilac hue, from June onwards. They are fine plants for the partially-shaded flower border, or for open spaces among shrubs if not too dry, and are excellent for edgings to large beds and borders.

As to varieties, there is one kind, however, which needs different conditions from most of the others, and that is F. subcordata grandiflora, sometimes known as the Corfu lily. While funkias generally are grown principally for their foliage, this is valued for its flowers, which come later in the summer than the others, generally not before August, and, instead of being a shade-loving plant, it needs a sunny spot in a well-drained soil if it is to do well in this country. It throws up its spikes of large white sweet-scented flowers in August and September, when most of the other kinds have finished. It is better grown in groups than as an edging. Its young foliage is liable to be preyed upon by slugs and snails, which need to be guarded against, as a leaf which is mutilated at this season is spoilt for the summer, and the plant disfigured.

The best kind of funkia to be grown chiefly for its foliage is F. Sieboldiana major, which has large glaucous leaves, sometimes a foot across, while its pale lilac racemes of flowers rise to a height of three feet. It is best grown in large, bold groups, and if well placed, so that other plants show up its bluish-green leaves, very fine effects may be produced with it. There is a variety of it with yellow-margined foliage, but many consider it no improvement. For the formation of a border to a large bed of sub-tropical plants these two varieties stand apart from the others. F. ovata has large deep green leaves of a glaucous hue, and there are varieties of it with leaves margined white and variegated gold. F. undulata has the leaves waved at the edges, and this, too, has a variegated kind, silver and green.

Alger Petts.

Plumbago rosea.—Now that the popular Plumbago capensis is over, or nearly so, its pretty relative Plumbago rosea is in a warm greenhouse unfolding its earliest blossoms. With reasonable care these will continue to develop throughout the winter, at which season flowers of all kinds are very valuable.—W. T.



THE REMARKABLE YEW HEDGE AT POWIS CASTLE.
The Seat of the Earl of Powis.

EVERGREEN HEDGES.—II.

The Box.

For a neat and handsome hedge, moderate in size, and easily kept in order, the box is well adapted. In some soils and situations the plant does not thrive, or the occasional severity of the climate may be against it, but in general it does well; and, at a distance from town smoke, and its usual accompaniments, is long lived. Soil of ordinary fertility, fairly well drained, and free from noxious weeds, is the principal requirement as a rooting medium. It is of slow growth, and continuous; very compact if clipping is well attended to yearly. This is best done in April, when the immediately succeeding growth quickly obliterates any unsightly traces of cutting. B. sempervirens closely resembles B. balearica, but shows, more or less, according to the season, some traces of variegation, otherwise there is nothing to choose between them, as both will reach a height of eight or ten feet, if so desired, but unless it be for some special object less than this is better, for the maintenance over a long period of a well and densely-furnished base. In passing, it may be mentioned that the three genera so far referred to lend themselves very readily to training into diverse shapes, as of birds, animals, garden seats, arbours, and castellated towers, a fashion certainly not much in favour at present, but, with a slight change of opinion and taste in the matter, might possibly be again in vogue long before the present century has run its course.

Coniferous Plants.

Thuia occidentalis (arborvitæ), T. Lobbi, Cupressus Lawsoniana, Juniperus chinensis, J. virginiana, and Retinospora obtusa, as well as several species in close affinity to these, are quick growing, and very ornamental subjects for forming divisional and shelter lines, or as screens for hiding from view unpleasing objects. The first-named is probably the favourite for this purpose. It succeeds in most places, and bears with impunity close clipping to keep it within reasonable bounds. The plants luxuriate in moist positions, and are not fastidious as to soil providing this is well pulverised before planting is done. Raised from seeds, transplanting should take place two years afterwards, in early spring, and this should be practised yearly until the plants are from two to three feet in height, when they may be transplanted to their respective permanent positions, and placed so that the foliage of one meets the other throughout the line. Pruning or clipping must follow in due course, and is best done in April, or before new growth is in evidence, to obviate the loss of sap, and consequent weakening of the plants. As to dimensions, this must rest entirely with the operator, and the special purposes of the hedge, but if eight feet in height is sufficient, a width of two feet at the base may be allowed, or even a trifle less if space is limited, and such will withstand snow and wind storms very satisfactorily. This treatment, as recommended for the arborvitæ, applies equally to the others, though, it may be stated, that the junipers and retinospora are of slower growth than it and the cupressus family.

MR. J. HONEYMAN'S FIRST PRIZE EIGHT VASES OF CHRYSANTHEMUMS AT EDINBURGH. THIS EXHIBIT WON THE SCOTTISH CHALLENGE CUP.

Privet.

This well-known plant can hardly be recommended for forming a substantial hedge, unless it be mixed with some other subject having a greater power of resistance, but for rapid growth, and quickness in forming an effective screen, it is excelled by no other. On the other hand, used in divisional lines about cultivated ground, and closely cut at intervals, it answers the purposes admirably, and maintains a very neat appearance.

Cotoneasters.

Two species of this genus at least are well adapted for hedges, namely, C. microphylla and C. Simonsi, the former being a low, dense grower, while the latter possesses the last-named qualification, and may be trained by pruning alone to reach any reasonable or requisite height. These are quite hardy, and succeed well in any fairly good soil, and may be closely trimmed at any season, while the dark, glossy foliage and the numerous scarlet berries borne upon the spur-like growths, renders a hedge of this kind very conspicuous in the winter season.

Butcher's Broom.

A plant that will endure shade is often an acquisition upon an estate, and the one in question is the most accommodating in this respect that I am acquainted with. As a hedge plant proper its diminutive stature is against it, as it seldom exceeds two feet, but as there are positions, such as raised mounds or banks, where a sturdy line of evergreens adds very considerably to the amenities of the situation, it is mentioned here. As stated, shade from trees has little or no ill effect upon it, and scarcely any care is required in its cultivation. Stock may be raised from seeds or by division of the plants, and the latter course is generally resorted to, as berries, which are freely produced in warm seasons, are apt to be taken by birds as they become ripe.

Its near prototype, Ruscus racemosus (the Alexandrian laurel), is equally suitable for the purpose, and is, moreover, a trifle taller in growth.

The several kinds of berberis, the common and the Portugal laurel, as well as Rhododendron ponticum, may all be pressed into service as hedge plants, and often prove useful near woodland walks and the more outlying portions of estates, where their somewhat rough, informal habit of growth is a welcome change to the excessive trimness prevailing in more central positions.

James Day.

Galloway House, Garlieston.

Cantua dependens.—This plant has become somewhat rare of late years, although possessing much beauty and in other respects desirable. It is of much value for training up pillars and over roof trellises, and also for house decoration. When flowering during the spring it has a fascinating appearance, and is easily propagated and readily grown. Yet it is not frequently seen in gardens.—W. A. Cook.

NOTES FROM KEW.

Greenhouse Flowers.

After being closed for painting, and other necessary repairs, the greenhouse No. 4 is once again gay with flowers. As might be expected at this season, chrysanthemums predominate, the various sections of this charming autumn flower being well represented. Decorative plants, rather than the production of large blooms, is the object aimed at, but, still the lovers of these last-named will find much to admire. There is a widespread idea that the choice of flowering subjects, other than chrysanthemums, is at this season an extremely limited one, but, as is well shown at Kew, a great many others are available for the purpose. Hard-wooded plants are represented by Crowea saligna, with its pretty rose-coloured blossoms; the Tasmanian Bauera rubioides, with salver-shaped flowers of a pleasing pink shade; and various heaths, notably four forms of the popular Erica gracilis, namely, the typical rosy-purple kind, the pure white nivalis, a pretty pink-flowered variety, and that known as vernalis, which is of a more upright habit than the others, and is only just unfolding its earliest blossoms. Erica hyemalis and Erica melanthera are also very effective.

Salvias and Begonias.

A particularly bold-growing form of Salvia splendens, under the varietal name of pyramidalis, supplies a brilliant scarlet colour, and a collection of bouvardias is also noteworthy. Chief among them are President Cleveland, scarlet; Vreelandi, white; Priory Beauty, pink; Mrs. Green, salmon-pink; King of Scarlets, scarlet, white tube; Maiden's Blush, pink; Alfred Neuner, white; President Garfield, pink; and Hogarth flore plena, red, these last three being double-flowered varieties.

Begonias of the Gloire de Lorraine section are bright and effective. Turnford Hall is still the best of the light-coloured varieties, and of the bright-tinted forms Rochfordi is particularly good. Other begonias in flower are Dregei, Weltoniensis, semperflorens gigantea rosea, Luzerna, and the continuous-blooming Corbeille de Feu.

Veronicas, etc.

Different flowering subjects worthy of special mention are veronicas, represented by several varieties; carnations, of sorts; Calceolaria Burbidgei, as valuable in the winter as it is out of doors in the summer; marguerites, particularly good for this time of the year; Impatiens Oliveri, rarely without its large mauve-coloured blossoms; Plumbago rosea, bright and cheerful; Nerines of sorts; Lasiandra macrantha, now past its best, but the few flowers remaining are still bright and effective; and Jacobinia chrysostephana, whose golden-orange crowns of blossoms are very distinct from anything else in bloom.

Although they cannot be regarded as flowering plants, yet a group of the different varieties of capsicum, laden with their curious fruits, form a bright and pleasing feature.

Costus igneus.

This member of the Ginger Wort family is a very showy stove plant, whose brilliant orange-coloured flowers stand out in a markedly conspicuous manner during the dull weather so often experienced at this season. From a thickened rootstock it pushes up leafy stems of a fleshy nature to a height of eighteen inches to two feet. The flowers, which are produced from a terminal head, are individually about three inches across. They are thin in texture, and do not last long, but a suc-

CHRYSANTHEMUMS
FOR
GARDEN AND GREENHOUSE.

By D. B. Crane, F.R.H.S.

A practical treatise on the Culture of early Flowering and Decorative Chrysanthemums—How and when to Plant—Management for the whole year—List of Varieties, with Description, Colour, Habit, Time of Flowering, etc.

Sixth edition. 110 pages. Fully Illustrated.

PRICE 1/-; by Post, 1/2 (Bound in Cloth, 1/6; by Post, 1/8).

CHRYSANTHEMUMS
AND HOW TO GROW THEM
FOR EXHIBITION.

By J. B. Wroe.

A Complete Guide to Growing for Exhibition—Propagation—Potting—Feeding—Timing and Stopping for Northern, Southern, and Midland Growers, etc., etc.

The two Books post free for 3s. 10d.

cession is kept up from one head for a considerable time. Now in flower, in the stove portion of the T range. This costus was introduced from Bahia in 1882, and considering its attractive flowers and easy culture, it is somewhat surprising that it is so rarely met with.

Browallia viscosa.

Of the browalias the comparatively large-flowered B. speciosa major has become a general favourite, but B. viscosa does not appear to be much known. The flowers are smaller than those of B. speciosa major, but richer in colour, while a conspicuous white eye adds to their effectiveness. It is easily grown, and, as shown by a group in the intermediate portion of the T range, is decidedly ornamental.

Nerine crispa.

Compared with several other species of nerine, and the many garden hybrids raised therefrom, this cannot by any means be regarded as showy. Still, as represented by a group of flowering examples in the cool portion of the T range, it is decidedly pleasing. This species is slender in all its parts, the segments of the flowers being very narrow, much undulated, and of a pale pink colour. It is also known by the rule, one of the latest to bloom.

MR. THOS. LUNT'S FIRST PRIZE FIFTEEN VASES OF CHRYSANTHEMUMS AT EDINBURGH. THIS EXHIBIT WON THE CITY OF EDINBURGH CHALLENGE CUP.

Adhatoda cydoniæfolia.

One does not often come across this Brazilian acanthad, yet it is an exceedingly pretty climber for furnishing the rafters in a small or medium-sized stove. Flowering, as it is, in the T range at this season, it is additionally welcome. The blossoms, which are borne in clusters at the points of the shoots, have a white tube and upper lip, this last being tinged with purple, while the large lower lip is wholly purple, with the exception of a white stripe down the centre. This adhatoda was introduced from Brazil as long ago as 1855, but it is very seldom met with in gardens.

Begonia Froebeli.

This begonia, which was introduced from Ecuador, is, although a member of the tuberous-rooted section, quite distinct from the others. The tuber is much less solid than in the ordinary kinds, consisting frequently, as it does, of little more than a dense mass of fibres. Both the leaves and flowers spring direct from the rootstock, as this species does not form a stem after the manner of the commonly cultivated tuberous-rooted kinds. Another distinctive feature is that the leaves are thickly clothed with hairs. The flowers are usually bright crimson or scarlet, there being a certain amount of individual variation in colour. Begonia Froebeli flowers during the autumn months, and is now in bloom in the T range. In its early days this begonia was considered likely to be of great value to the hybridist, but I am not aware that it was ever successfully crossed with the ordinary tuberous kinds. Between it and B. polypetala Messrs. eitch obtained a hybrid, which, under the name of B. incomparabilis, was given an Award of Merit in November, 1905.

Heliophila scandens.

Interesting as being one of the very few climbing members of the Crucifer family, and valuable from the fact that its pure white blossoms are borne in great freedom during the present season, this heliophila, now in full bloom in the succulent house, merits a passing notice. It is a climber of moderate vigour, whose wiry stems are clothed with lanceolate leaves from one to two inches in length, and rather thick in texture. The flowers, which are borne in loose racemes, are of the characteristic shape common to crucifers in general. This plant was introduced from Natal in 1885. Outside of a botanic garden it is, however, but little known.

Camellia sasanque.

Although Professor Sargent, in the "Forest Flora of Japan," says this camellia is perhaps more commonly met with in Japanese gardens than C. japonica itself, it is, in this country at least, much less grown. Compared with C. japonica it is of slender growth, while the shoots and minor branches are far more numerous, and the leaves much smaller. A notable feature is the fact that it blooms during the late autumn and early winter months. The flowers of the typical kind are single, from three to four inches in diameter, and of a lilac-rose colour. A large cluster of yellow stamens in the centre of the flower stand out in a conspicuous manner. There is a variety with white flowers. Both this and the type are now in bloom in the cool portion of the Temperate House.

K.

FORESTRY DEGREE AT ABERDEEN UNIVERSITY.

Among the business which was disposed of at the meeting of the Aberdeen University Court on Tuesday, the 14th inst., was a question of much interest to foresters. Principal George Adam Smith presided, and a memorandum was submitted by the senatus, of the University representing that, in view of possible developments in forestry in Scotland, and the suitableness of Aberdeen as a centre of education in forestry, the time had come for the institution at the University of a degree of Bachelor of Science in Forestry. After discussion, the Principal moved, and Sir John Fleming seconded, a resolution approving generally of the institution of such a degree.

It may be interesting to note that this decision involves the creation of a forestry course in the Faculty of Science qualifying for such a degree. The course will consist of two sections, the first examination including the general scientific subjects of botany, zoology, natural philosophy, and chemistry, while the final examination, and the major part of the course, will consist of the subject of forestry in its various departments. A three-years' course is projected; and during this course it is intended that students shall keep in close touch with practical work in the forests. Thus, before commencing his studies of sylviculture a student will be expected to have acquired a certain amount of practical knowledge by a period of residence of at least six months in a forest. In the two last years of his course, moreover, he will have to spend some weeks in the woods under practical tuition.

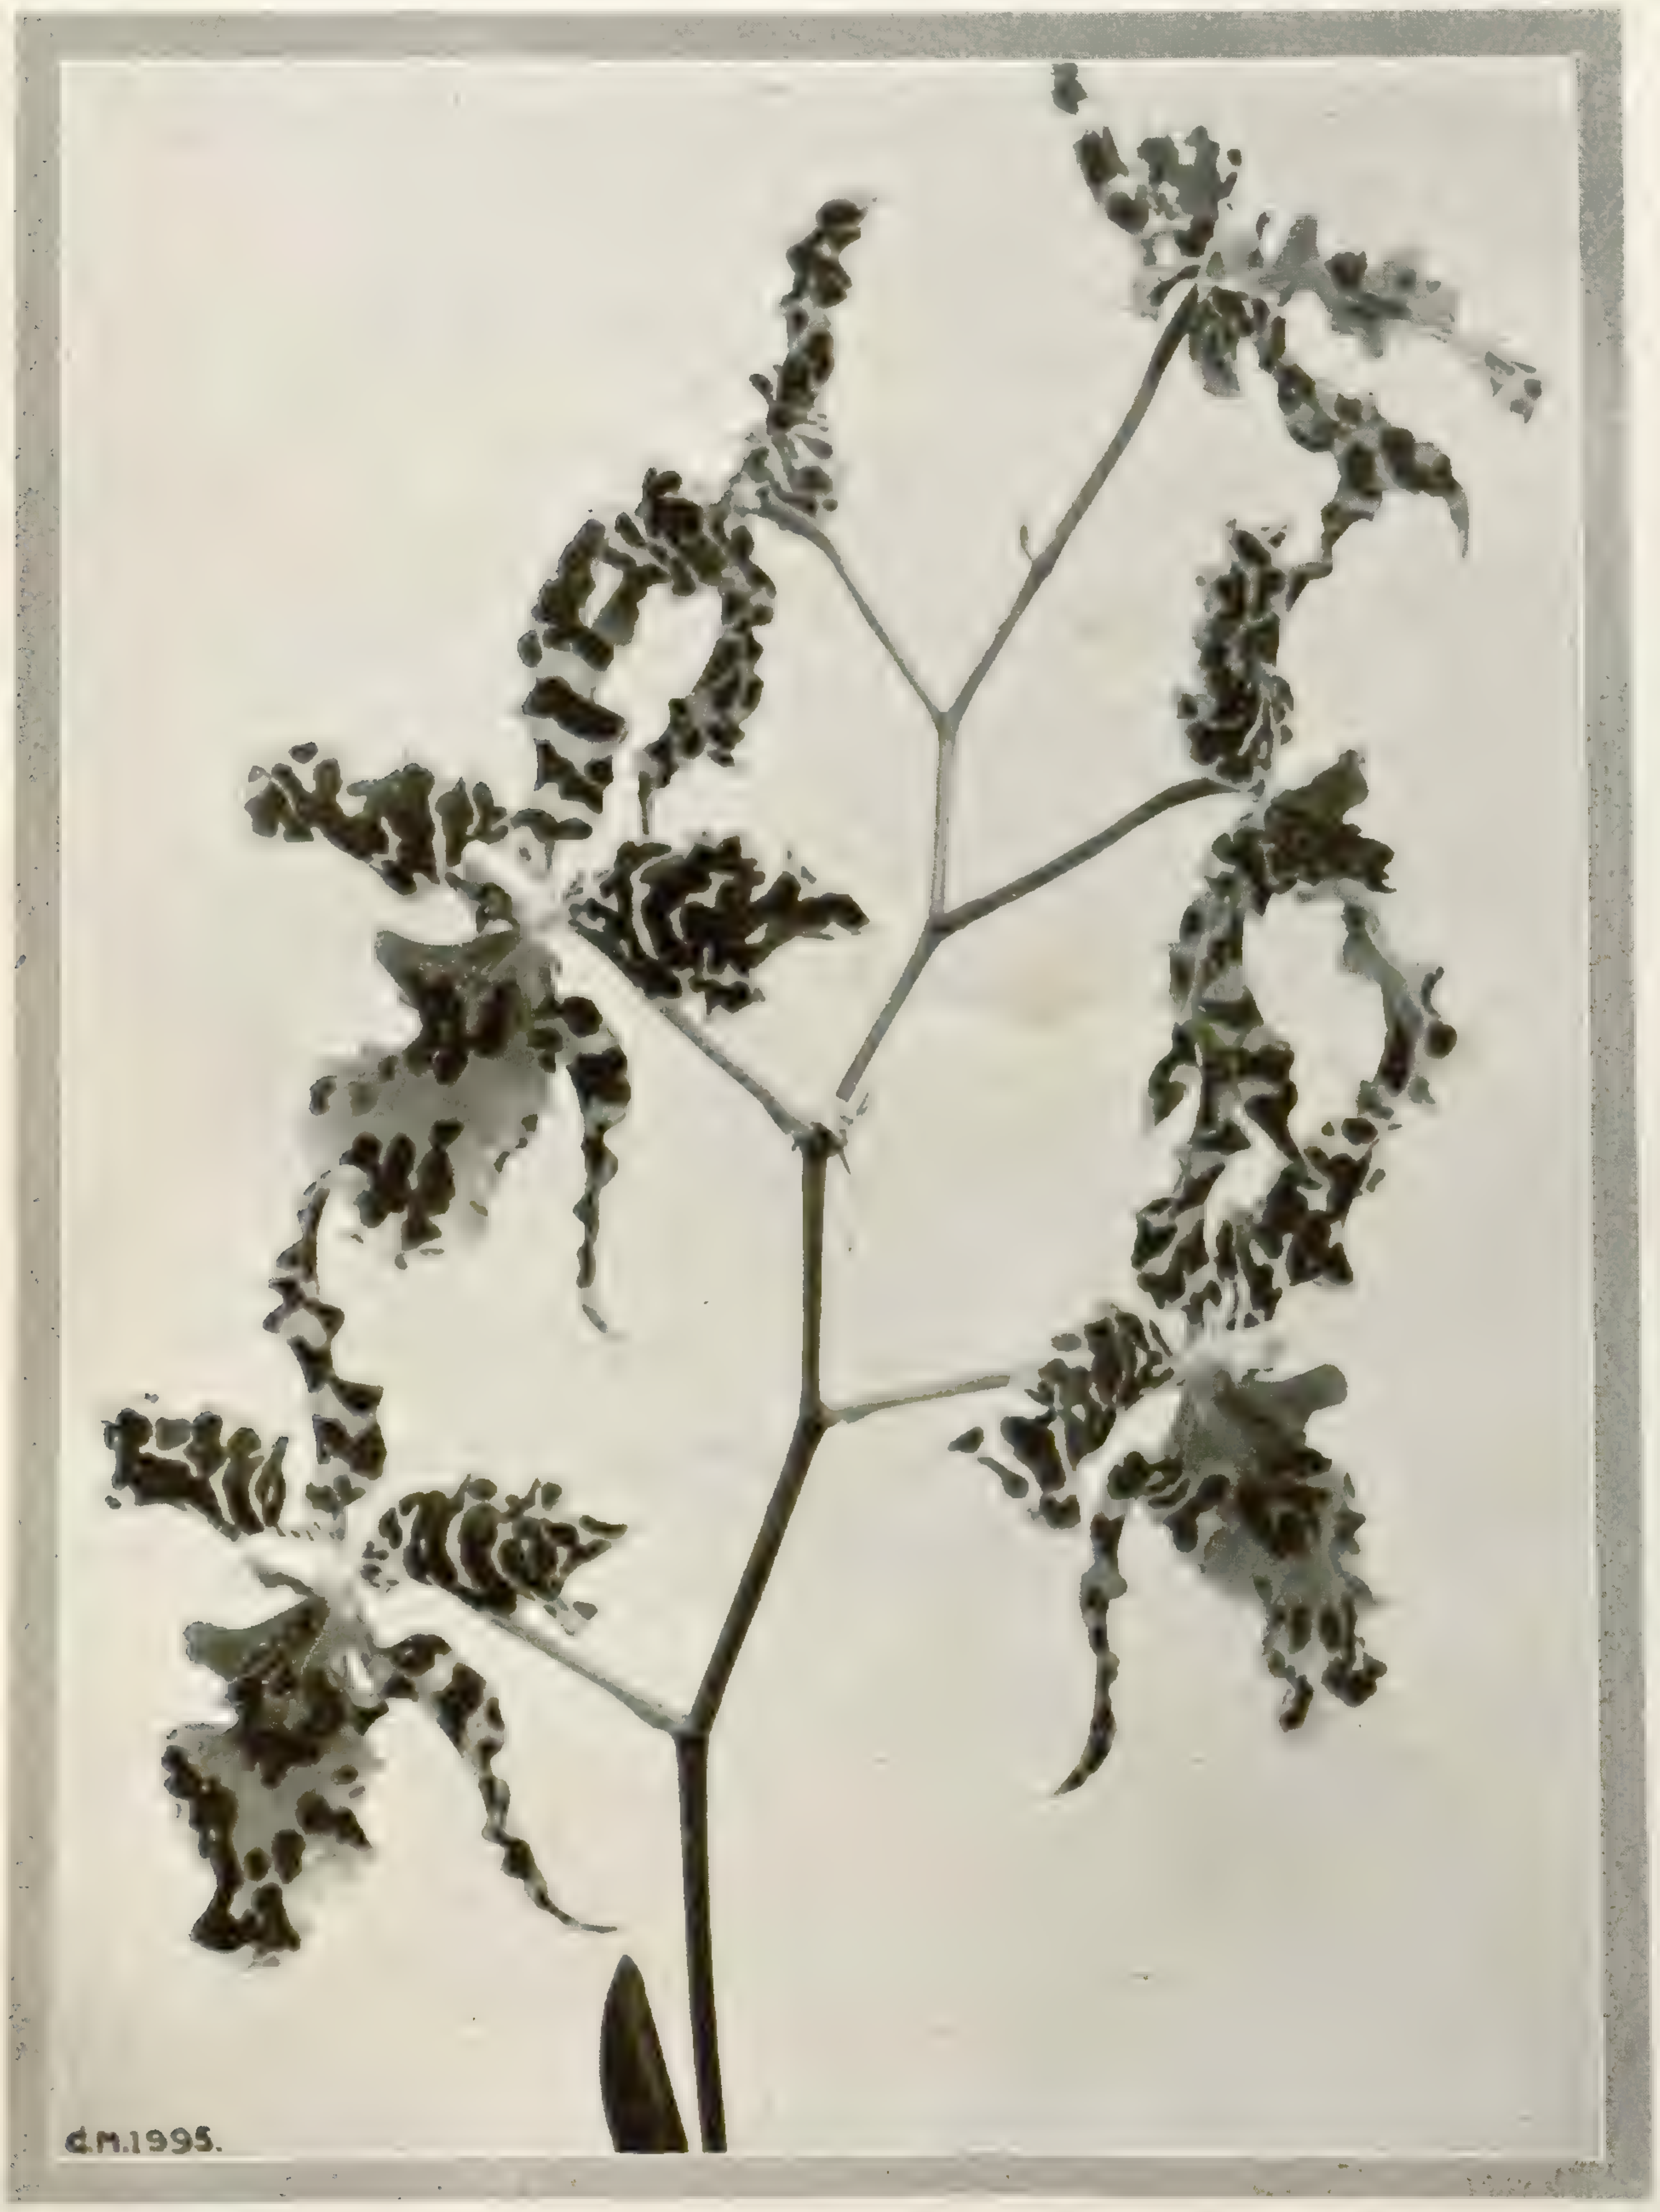
The subjects of class study for the new degree will be, so far as the first B.Sc. examination is concerned, the subjects as mentioned above in the ordinary degree classes at present held in the University. For the final examination a number of new courses will require to be instituted, and these will comprise: Forest botany, embracing the study of trees and shrubs, classification, etc., as well as of the diseases of trees; forest zoology, embracing the study of insects and other animals of importance in forestry; forest law and forest policy; outlines of forestry, a general subject; sylviculture, including the study of forest growth, planting, etc.; management and valuation; protection of woodlands; and utilisation of forest products. Along with these courses will go the study of subjects such as land surveying, geology, and economics, which are more or less covered by existing courses in the University.

NEW PLANTS, ETC.

CHRYSANTHEMUMS.

Golden Cap. — A splendid decorative variety, also known as Yellow Cap. It is probably a sport from Caprice du Printemps, as it favours the latter in form and habit, but its blooms are of a rich golden yellow hue. A.M., R.H.S., November 7. Messrs. W. Wells and Co., Merstham; and Messrs. James Veitch and Sons, Chelsea.

Golden King.—A very big incurved variety that, under good culture and careful dressing, should become a popular exhibition sort. The colour is deep golden yellow. A.M., R.H.S., November 7. Messrs. W. Wells and Co., Merstham.



ODONTOCIDIUM FOWLERIANUM.
Flowers buff, red-brown, and yellow. Certificate of Appreciation, R.H.S., November 7. J. Gurney Fowler, Esq., The Glebelands, South Woodford.

Mrs. Andrew Walker.—A handsome and free-flowering sport, from the popular Freda Bedford, a capital decorative variety; the newcomer has deep reddish-bronze flowers. A.M., R.H.S., November 7. Messrs. W. Wells and Co. F.C.C., N.C.S., November 1.

Percy Arnold.—A particularly handsome single variety, of good size, and with stiff erect stems. The graceful flowers are rich deep pink, with a zone of white round the disc. A.M., R.H.S., November 7. Mr. W. G. Rigden, Englefield Green.

Snowflake.—A large single variety, with very broad pure white florets. A.M., R.H.S., November 7. Mr. P. Ladds, Swanley.

Celia.—A finely formed single variety of great beauty; clear shining yellow. F.C.C., N.C.S., November 1. Messrs. Cragg, Harrison, and Cragg, Hounslow.

Mrs. Percy Wiseman.—An incurved variety of excellent form and soft primrose-yellow colour. F.C.C., N.C.S., November 1. Mr. P. Wiseman, Woodham Walter.

Caterham Bronze.—A single variety of rich ruddy bronze hue; very attractive. F.C.C., N.C.S., November 1. Mr. Frank Brazier, Caterham.

Charles Dickens.—This is another splendid golden-yellow single variety, of excellent form and substance. F.C.C., N.C.S., November 1. Mr. Norman Davis, Framfield.

Heston Bronze.—A decorative variety of good size and habit; the flowers are very graceful, and a soft, light, bronzy shade of colour. F.C.C., N.C.S., November 1. Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow.

Miss Margaret Walker.—A beautiful single variety, the colour being rich golden-bronze. F.C.C., N.C.S., November 1. Messrs. W. Wells and Co., Merstham.

Mrs. John Peed.—A large single variety of graceful form; bright yellow. F.C.C., N.C.S., November 1. Messrs. J. Peed and Son, West Norwood.

Dorothy Dan.—A deep terra-cotta coloured single variety, shaded with bronze. Commended, N.C.S., November 1. Messrs. W. Wells and Co., Merstham.

Shoreham Oldfold.—A medium-sized single variety; rich old-gold colour. Commended N.C.S., November 1. Mr. Lawrence.

R. B. Burge.—A single white variety of good form and size. Commended, N.C.S., November 1. Mr. P. Ladds, Swanley.

White Beauty.—Another white single variety of fine form, purity, and substance. Commended, N.C.S., November 1. Mr. W. Higgs, Fetcham Park Gardens, Leatherhead.

WINTER-FLOWERING BEGONIAS.

Exquisite.—This is a splendid addition to the winter-flowering race, as it produces quite large single blooms of great beauty; these are of a pretty pink shade, heavily flushed towards the tips of the segments with rosy carmine. A.M., R.H.S., November 7. Messrs. James Veitch and Sons, Chelsea.

Acquisition.—In this fine variety the habit of growth is excellent, and the flowers of good size; the colour is pale pink, a very pretty shade. A.M., R.H.S., November 7. Messrs. James Veitch and Sons.

Her Majesty.—One of the three new varieties, this gives the most distinct colouring, its large flowers being yellow, with rosy suffusion, and giving an apricot effect of great beauty. A.M., R.H.S., November 7. Messrs. James Veitch and Sons.

CARNATION BARONESS DE BRIENEN

The bright pink shade of this fine perpetual carnation is peculiarly attractive, owing to the deep tint at the base of each petal, which produces a glow that is distinctly pretty. The flowers are of good size, and the petals are elegantly fringed. A.M., R.H.S., November 7. Messrs. Stuart Low and Co., Enfield.

CALANTHE COOKSONÆ.

Hitherto the beautiful Calanthe Harrisi has been regarded as the finest pure white member of the genus, but pride of place must now be given to C. Cooksonæ, which has flowers of large size, and great purity. C. Harrisi was one parent. F.C.C., R.H.S., November 7. Mrs. Norman Cookson (gardener, Mr. H. J. Chapman), Oakwood, Wylam-on-Tyne.

CATTLEYA ASHTONI ALBA.

This is a very beautiful cattleya, the flowers being quite white, save for a little yellow shading on the throat of the labellum. The parents are C. Harrisoniana and C. Warscewiczi, presumably a white form of each. F.C.C., R.H.S., November 7. Messrs. Sander and Sons, St. Albans.

ODONTICIDIUM FOWLERIANUM.

A most interesting hybrid obtained by crossing Odontoglossum cirrhosum with Oncidium Forbesi. The erect spike on the small plant shown carried numerous flowers of medium size; sepals and petals buff, barred and blotched with deep red-brown; lip bright yellow, with spots of bright red-brown. Certificate of appreciation, R.H.S., November 7. J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), Glebelands, South Woodford.

CATTLEYA VENUS LUTESCENS.

A handsome variety of the hybrid between C. Ives and C. Dowiana aurea. It has soft yellow sepals and petals and a large, rich rose-purple lip, veined with yellow at the base. A.M., R.H.S., November 1. Messrs. J. and A. McBean, Cooksbridge, Sussex.

CYPRIPEDIUM SYBIL SUPERBUM.

A handsome orchid with large, bold flowers. The white dorsal sepal is finely lined, and striped with purple, and shaded with green at the base. The deflected petals show the influence of C. Fairrieanum, and are greenish, heavily spotted, and shaded with dark purple. The lip is green and purple. The parents are C. Franciscæ and C. Fairrieanum. A.M., R.H.S., November 7. Mrs. Norman Cookson, Oakwood, Wylam-on-Tyne.

PROFITABLE WOODLANDS.

(Continued from page 854.)

Amongst other hardwoods on soils which may not be suitable to the growth of oak and ash, say, on the limestone and chalky soils, and at higher elevations, beech will prove one of the most profitable timbers. I believe I am correct in saying that in the large chair-making districts in Bucks only 10 per cent. of the beech used in that industry is home-grown, the reason being that the supply of beech timber grown in the neighbourhood is so scarce, although it has been stated by a very responsible authority that beech woods on the Chiltern Hills have showed an annual income of 30s. per acre per annum, and adjoining agricultural land was letting as low as 5s. per acre. No doubt it is the long period that must elapse ere beech woods can be expected to yield a profit that prevents landowners investing their capital in planting large areas of this timber. I should be glad to see the day come when all plantations up to the age of fifteen years are exempt from all taxes and tithes; it would cause landowners to take more interest in afforestation.

In low-lying, but fairly well-drained, land black Italian poplar is a tree that will pay for cultivation, and there is, especially in the Midlands and the north, a very good demand for this quick-growing timber.

Among the conifer timbers larch is considered one of the quickest growing, and also the most profitable, and I am afraid that, chiefly on these grounds, it has been planted indiscriminately, for on many estates we find it planted in soil and situation quite unsuitable for its growth, and never likely to make a profitable return. The most suitable land, in my experience, to plant larch is in light sandy loam, or even pure strong sand. Personally, for commercial purposes, I prefer planting larch woods pure, except where exposed to the south and west winds, when it is advisable to plant a border, say, of Austrian pine, as a shelter. On the Gloucester portion of Earl Beauchamp's estates the main portion of woodlands planted during the past forty years consists of 95 per cent. larch; the soil is a deep fresh sand, overlying the old red sandstone rock, and one of the best of the woodlands there is one of twenty-four acres, twenty-one years planted, and it contains 99 per cent. of larch. I have seen very little disease among the trees, and if it is noticed my foreman removes the trees in autumn. I had this plantation thinned first at ten years, again at fifteen years, and it is examined now every autumn for the removal of unhealthy or suppressed trees. There are slightly over 1,000 trees to the acre, averaging 2¼ cut feet each. This is the plantation that was awarded first prize (for best conifers) in the Plantation Competition in connection with the Royal Agricultural Society's Show at Gloucester, 1909.

This plantation is, I think, a living example to show that on proper soil and situation larch is the most profitable crop to grow. Although larch thinnings suitable for hop poles are not now so much in demand, there is quite a ready sale for them for rustic work, and the larger sizes are in demand for pitwood and fencing. The agricultural rent of this land, before planting, was about 6s. per acre, being on the east slope of very hilly ground, and only fit for a sheep run.

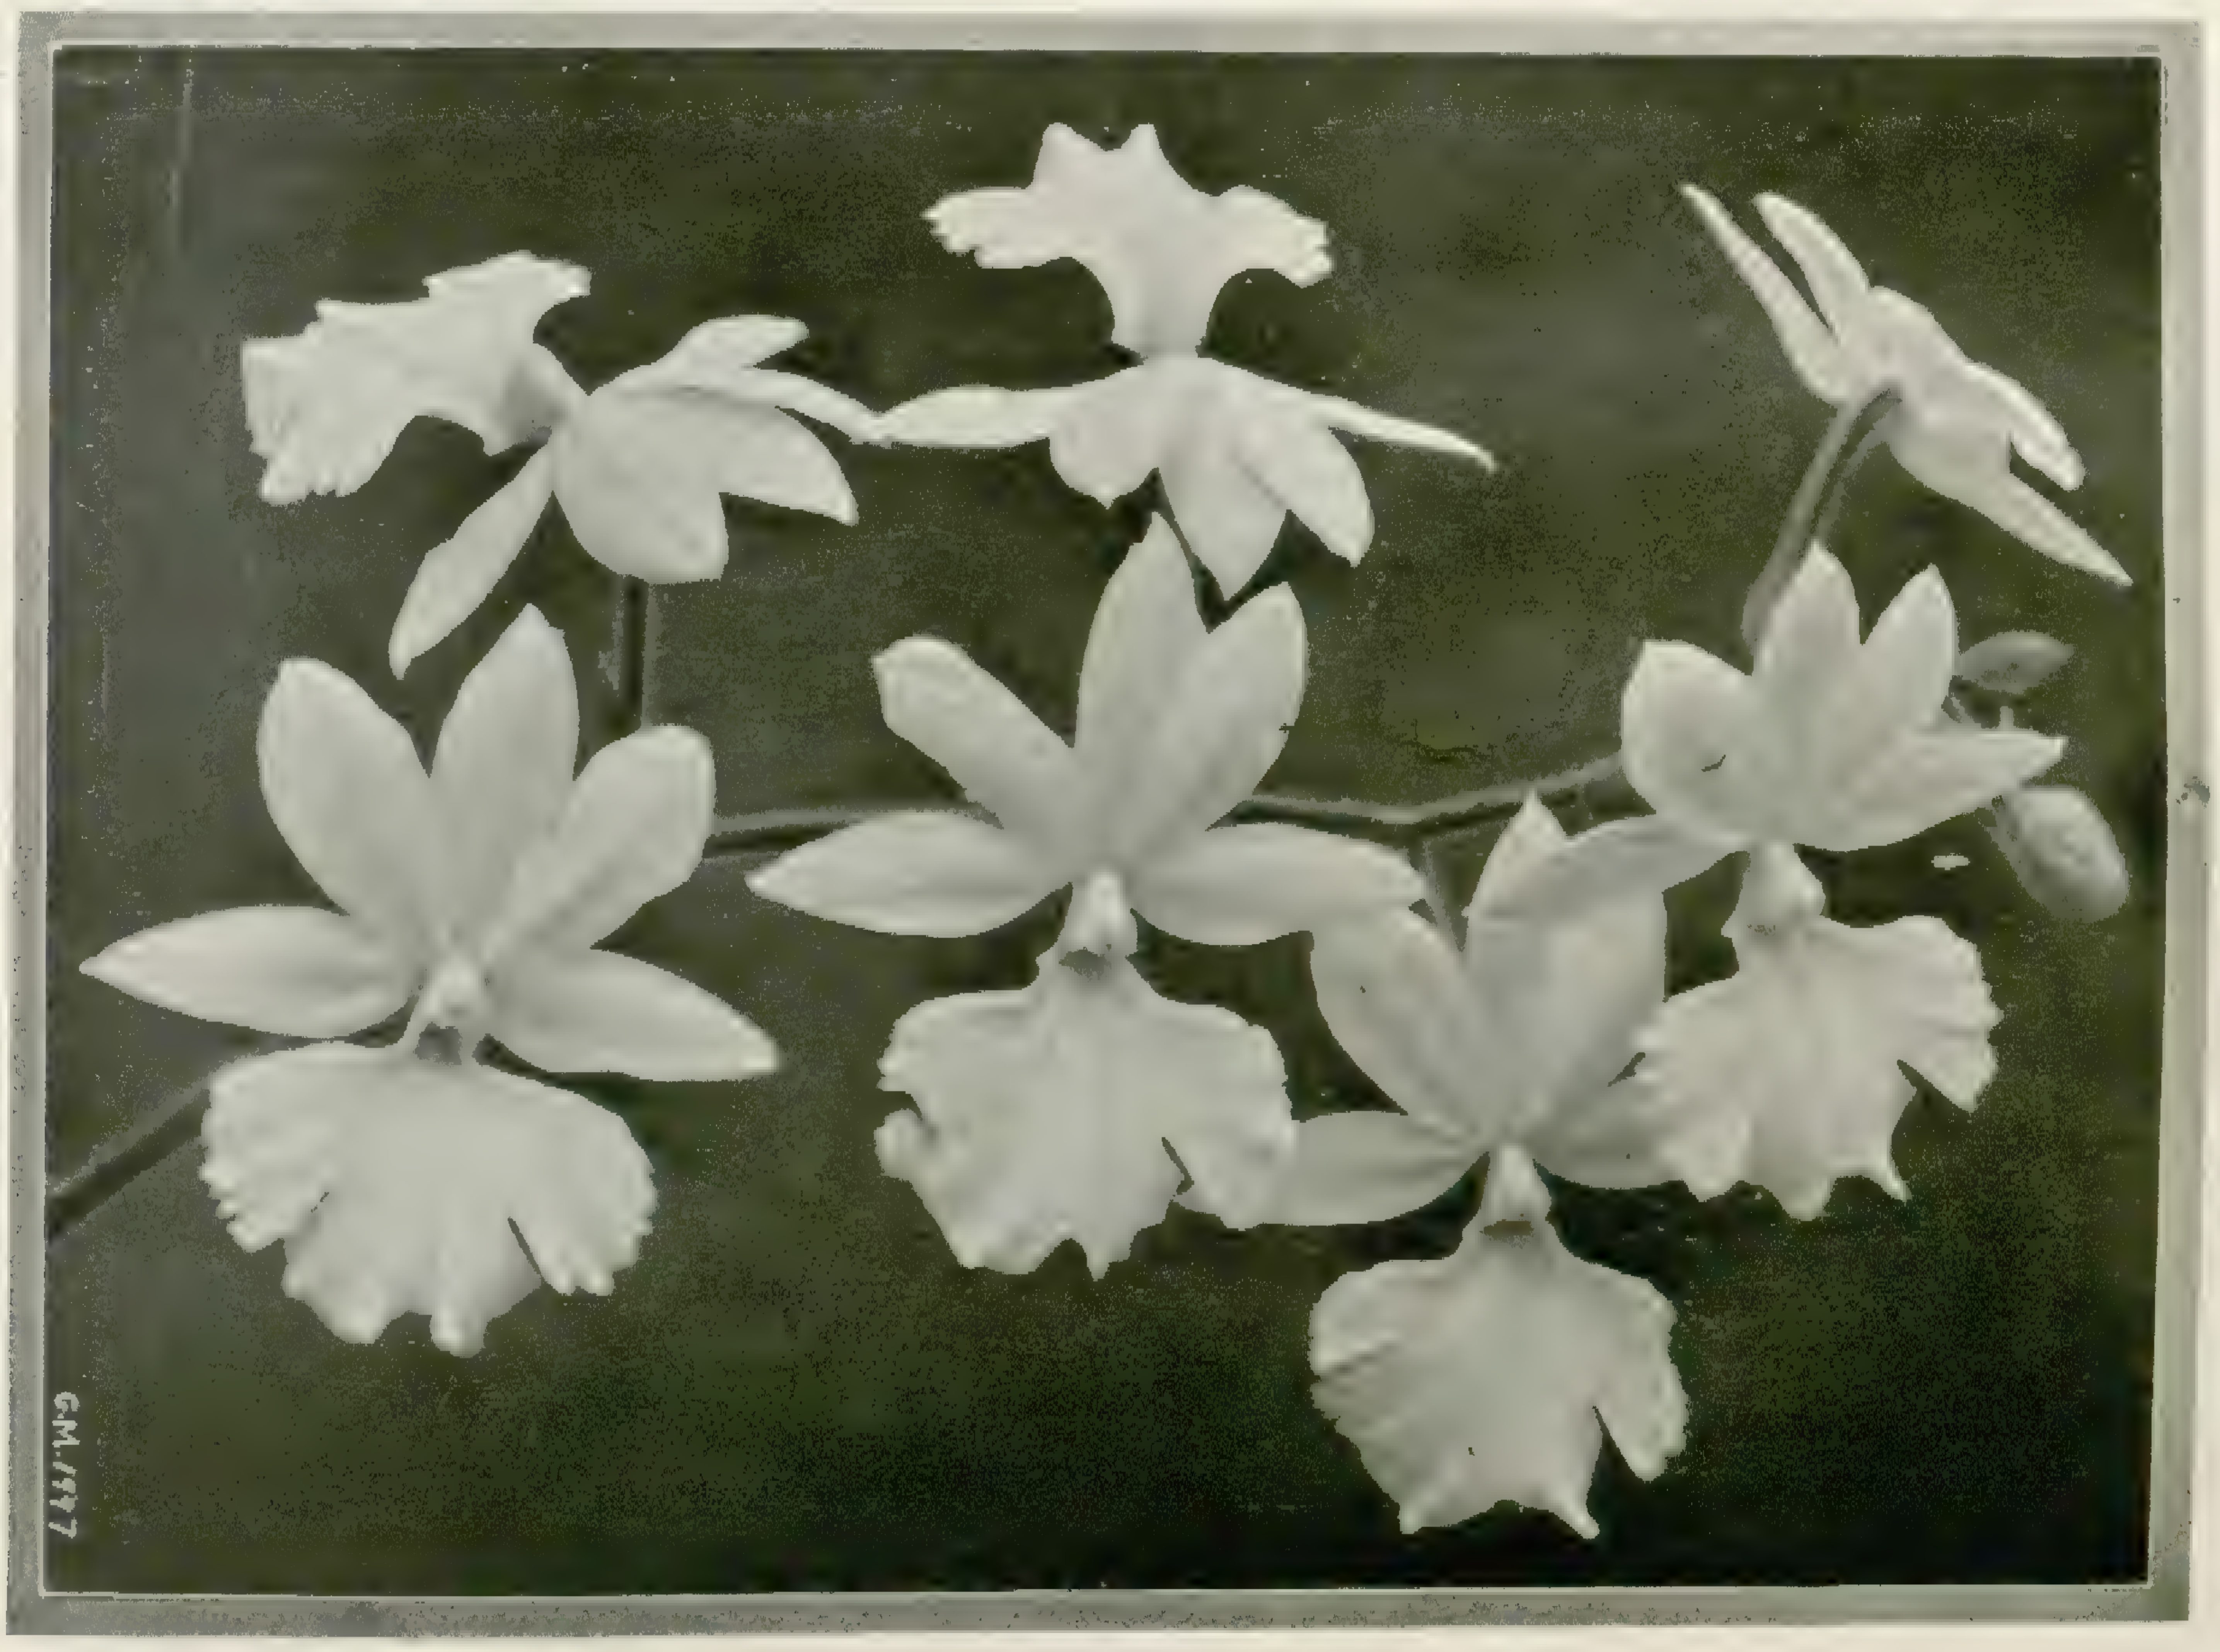
For planting in this country I would as soon use the Tyrolese as the native larch. I believe it is hardier, and grows quicker after the first few years; but I prefer either sort reared in the seed beds in this country—rather than reared abroad. Japanese larch (owing greatly to the scarcity of seed) had been too expensive to plant, from a commercial point of view, although I have found it freer from disease where the other varieties have suffered, and and it is not liable to injury in lower-lying ground, where frosts are apt to take hold of its compatriots.

Where the soil is light and sandy, and the site not too exposed, Douglas fir is a very profitable tree to grow, as it can now be bought from the nurserymen at a very moderate price for two-year seedlings, and if planted (in lines) in the home nursery for two years it will be quite large enough for planting out. To grow good, straight, saleable timber, plant pine not more than four feet apart.

On the poorer and barren soils Scots pine and Corsican pine may be grown, and in many cases they have proved a good investment to the planter. One of the heaviest items on many estates where new plantations are formed is the expense of wire netting to exclude the forester's foe—the rabbit. It adds, according to area planted, from 20s. to 40s. per acre to the first cost of a new plantation. No doubt many of our woodlands would be more remunerative if rabbits were all enclosed in proper rabbit warrens, which is the proper place for them. In conclusion, the larger area that is taken to form a new plantation the less per acre is the cost of fencing and enclosing, and the larger woods are more economically worked, and more likely to prove a profitable success than woodlands of two or three acres.

ALEX. SLATER.

Malvern.



CALANTHE COOKSONÆ.

Flowers pure white. F.C.C., R.H.S., November 7. Mrs. Norman Cookson, Oakwood, Wylam-on-Tyne.

BEST PLANTS FOR GREENHOUSE.—Nearly 300 pages are devoted to the description, propagation, and culture of the best flowers and plants for the greenhouse in THE AMATEUR'S GREENHOUSE, by T. W Sanders, price 5s. net, or by post 5s. 6d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

HARDY SHRUBS FOR FORCING.

Among the great changes that have taken place in horticultural matters within the last two decades or so, a prominent one is the increased number of hardy shrubs that are now forced prematurely into bloom for the embellishment of the greenhouse or conservatory during the early months of the year. For a very long period a few subjects have been so treated, but the list of those which have proved available for the purpose has been largely added to within recent years. The great decorative value of the various hardy shrubs when forced into bloom is each season well illustrated at the early spring meetings of the Royal Horticultural Society, where the display they produce is fully equal to that of any tender subject.

From the fact that the different hardy shrubs intended for forcing do not all require the same treatment, no hard and fast line can be laid down in this respect, though for the production of flower buds full exposure to air and sunshine is, during the summer months, absolutely necessary. A few may, with careful treatment, be forced year after year, but in many cases two batches are grown, to be forced in alternate years.

A very essential point in connection with these shrubs after flowering is that they be protected until the cold snaps of weather are over, otherwise the tender foliage will be so injured that the plants take a very long time to recover. In making any selection of shrubs available for forcing it must be borne in mind that nearly all early-flowering subjects will submit to this mode of treatment, but the best are those given below.

An enormous number of seedling bushes of Azalea mollis, each bristling with flower buds, are sent to this country every year from Holland, and disposed of at a cheap rate. As they are raised from seeds the flowers vary from pale yellow to reddish-orange. The named kinds, of which there is now a considerable choice, are much superior to the seedlings, and possess a wider range of colour. A great favourite is Anthony Koster, with blossom of a rich golden-orange tint. The different Ghent azaleas are also of great value for forcing, being, from their looser habit and smaller flowers, less lumpy than the others.

All the above are by botanists included in the genus Rhododendron, of which the early-flowering evergreen kinds are of great value in the greenhouse, but they must not be forced as hard as Azalea mollis and its forms. Of the earliest to bloom, Cunningham's White and Prince Camille de Rohan are noteworthy examples. A prominent characteristic of these azaleas and rhododendrons is their dense mass of fibrous roots, owing to which they can be lifted and potted with scarcely any check. This feature is shared by the other members of the Heath family, among which Erica lusitanica and Erica Veitchi, Kalmia latifolia, Pieris floribunda, and Pieris japonica are suitable for forcing.

Lilacs are also general favourites, and their fragrant blossoms are much appreciated. The most popular of all for forcing is the pure white Marie Legraye, but all the forms, single as well as double, will readily conform to this mode of treatment. The members of the Rose order (Rosaceæ) contribute largely towards the brightness of our gardens in spring, and a great many may be readily forced. Among them may be noted Amelanchier canadensis, with white blossoms; Kerria japonica flore plena, with golden rose-like blossoms; and the different kinds of prunus, under which head is now included the cherries, plums, almonds, and peaches. Of the cherries, the variety J. H. Veitch is particularly noteworthy, and of the plums, the most select for this purpose are Prunus japonica, P. triloba, and P. Pissardi. The rich-coloured varieties of the peach, such as magnifica, are most effective. Several pyruses, too, are very pretty, though they do not last long. In addition to these there are the thorns, both single and double, and some of the spiræas, among the best being being S. arguta, S. confusa, S. Van Houttei, S. Thunbergi, and S. prunifolia flore plena.

Brooms of different sorts, either as dwarfs or standards, form a very pleasing feature in a collection of forced shrubs, while clematises are more year by year grown for this purpose. Deutzias have long been popular, but whereas at one time D. gracilis was the only representative, several of the pretty hybrid kinds are now available. Forsythia suspensa is, when grown as a loose bush, very effective for grouping purposes, the long drooping shoots being laden with pretty yellow blossoms.

The blossoms of some of the magnolias stamp them as unique among forced shrubs, while the pretty little Magnolia stellata readily forces, and the blooms remain fresh a considerable time. Laburnums, with their pendulous racemes of golden blossoms, are always admired; and though they are not often seen, yet those two flowering currants, Ribes aureum and Ribes sanguineum, are very pleasing when treated in this way. Wistaria sinensis is one of those subjects that has only been generally employed for forcing within recent years; now it is largely grown for the purpose. In standard form the long drooping racemes of pea-shaped blossoms are seen to great advantage, in colour they stand out distinct from all their associates.

The Guelder rose and its Japanese representative, Viburnum plicatum, must on no account be passed over, and the weigelas are also amenable to forcing, the most generally grown for this purpose being the crimson Eva Rathke. A well known forcing shrub is Staphylea colchica, with drooping clusters of fragrant white blossoms. Other subjects might be named, but the above form a good selection. W. T.

MR. J. COCKER'S FIRST PRIZE COLLECTION OF TWELVE DISHES OF HARDY FRUITS AT NEWCASTLE.

Lasiandra macrantha.—I was much interested in the reference that was made on page 848 to this delightful late summer and autumn-flowering shrub. Your able correspondent directs special attention to its adaptability to culture in cool houses, and with what he has written I am in full agreement. We have several plants at Leonardslee that are growing in a structure which is devoted chiefly to rhododendrons, and is not heated except when necessary to exclude frost. In this they have flowered, and are still flowering well; and in a greenhouse with a temperature ranging from 50 to 55 deg. we have plants that have been in bloom since August. During the summer this lasiandra thrives in the open. It is interesting to know that when cut every bud on the sprays will attain full development, and a friend of ours had a branch in a bedroom which retained its freshness for three weeks, and each bud developed into a flower of full size.—W. A. Cook.

FORCING FRENCH BEANS.

French beans are esteemed at any time of the year, but especially are they appreciated during the winter and early spring months, when supplies can only be obtained from glass-grown plants. Like a few other vegetables, French beans are, when well grown, almost, if not quite, as delicate in flavour, grown under glass as when produced in the open. No great skill is required to ensure an unbroken supply, but assiduous attention to details is essential.

A good batch of plants in full bearing at this date will prove of immense value to the gardener who is expected to supply during the winter and spring choice vegetables that require artificial heat, and the shelter of glass, in their production. High-class vegetables will undoubtedly be doubly appreciated during the coming winter, for the drought experienced in the past summer has greatly diminished the supplies of some kinds that are usually available from the open quarters.

I prefer to raise the first batch of French beans for forcing on a half-spent hotbed, sowing the seed in lines, and thinning the plants to about twelve inches apart. They are grown cool, and as soon as they are well out of the seed-leaf stage are lifted carefully with a good ball of soil, and placed two or three together in ten-inch pots. The compost used consists of three-fifths loam, broken with the hand, one of flaky leaf-soil, and one of fairly dry decomposed cow manure, or the manure from a spent mushroom bed. The materials are well mixed, and used lumpy. A sprinkling of soot and powdered charcoal is also of benefit. Any stagnation about the roots is fatal, therefore an open soil and ample drainage are important. A humid atmosphere should be maintained, except when flowering, and the plants fully exposed to the light. Red spider can only be kept in check by maintaining a liberal degree of atmospheric humidity, and extra attention must be given to this detail if the plants are near the hot-water pipes.

As soon as the plants forming the first batch are established in the pots, a second sowing should be made in 60-sized pots filled with rich loam. Put five seeds in each pot, and plunge the pots in the propagating bed to ensure quick and regular germination. When the seedlings are three or four inches high place them on a shelf near the roof glass, in a structure in which a temperature of about 70 degrees is maintained. Shift into the fruiting pots, which should be six inches in diameter, for this and subsequent sowings. This is the best size until the days begin to lengthen, when ten-inch pots are the best.

The best results are achieved where a small, low, span house can be specially devoted to French beans, as the plants are then under full control. H. T. Martin.

MR. ALEXANDER'S FIRST PRIZE COLLECTION OF TWELVE DISHES OF APPLES AT NEWCASTLE.

CALANTHES.

These beautiful orchids rank high among winter-flowering plants, and in gardens where there is a brisk demand for choice cut flowers during the dull months of the year they are worthy of extensive cultivation. The tall, arching flower spikes, when perfectly developed, are most graceful, and render well-grown plants very striking objects. Whether used for the embellishment of the conservatory, the adornment of the dwelling-house, or the decoration of the dinner table, they are invariably admired. For the latter purpose probably no flower surpasses them in grace and beauty, and when used in association with a few fronds of Nephrolepsis Piersoni they are seen to excellent advantage.

March is the best time to begin their cultivation, for at that period the pseudo bulbs commence new growth. Several bulbs may be placed in a fair-sized pan, or they can be grown separately in 32-sized pots. Either method gives good results, and it is simply a matter of the kind of specimens required when in bloom. Those in pans form striking objects for use in an uncut state. The pots, or pans, must be perfectly clean, and well crocked. Various composts are recommended for the successful cultivation of calanthes, and no doubt all give good results. I have found a mixture consisting of equal parts of good fibrous loam and dried cow manure suits them admirably. This should be carefully pulled to pieces by hand, and have a little crushed charcoal and silver sand mixed with it. In this calanthes thrive, and produce strong pseudo-bulbs, and stout handsome flower spikes.

In potting make the bulbs quite firm, and leave a space of about half an inch at the top of the pots. During the early stages of growth moisture at the root must be given with care, as a saturated rooting medium will often result in the dreaded leaf spot disease. Spray them overhead twice daily when fine, also damp the vacant spaces of the house betweentimes, shade lightly from bright sunshine, and maintain a minimum temperature of 70 degrees until September, when five degrees less will be more suitable. When the pots are full of roots liquid manure and soot water will be beneficial, and these may be mixed or given at alternate waterings. This I find is more helpful than applying a top-dressing of a prepared compost.

Should any scale or other insect pests put in an appearance they should be destroyed by the application of some approved insecticide. During the autumn gradually expose the plants to more sun by removing the shading early in the afternoon. From then onward give water more sparingly, but continue to feed while the flower spikes are developing. Do not withhold water entirely, however, until about January, when it will be necessary to give the bulbs a rest.

Calanthes are the most attractive when the flower spikes are in contrast with their own foliage, and when the leaves can be kept fresh, while they are in flower, it will be an advantage; if water is not withheld too soon it is possible to keep the leaves in a fresh state for some considerable time. Rather than retain dingy foliage, however, cut off leaves that are not in a fresh state, and fill in the base with adiantums, associate small palms as foliage with the flowers. When they are in bloom a temperature of about 60 degrees is the most suitable, and the atmosphere must be kept fairly dry, or the flowers will quickly damp. There are several meritorious varieties, but C. Veitchi, a beautiful rich pink, with an almost white throat, is probably the most charming and effective for general purposes. C. Bella, C. vestita rubro-oculata, and C. vestita lutea oculata are all attractive, and worthy of cultivation.

J. Gardner.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

EAST INDIAN HOUSE.—The various species of Aerides, Succolabium, Rhynchostylis, Vanda tricolor, and its allies, will now have completed their growths, and, as root action ceases, the green tips of the roots will become sealed over. When this is apparent careful watering will be necessary; in fact, only sufficient water will be required during the next few weeks to keep the leaves in a normally plump state. It is a good plan to syringe freely between the plants on all favourable occasions, but care should now be observed to see that all damping is done sufficiently early in the day to enable any excess of moisture drying before the cool evening temperatures are reached.

ANGRÆCUM SESQUIPIDALE, of which there are two varieties, one that flowers late in the autumn, and the other which blooms during the summer. I have always found that both these plants require warm treatment all the year round, and a reasonably humid atmosphere should be retained about them at all seasons. Where they are grown under warm conditions through the winter they must not remain long in a dry state at the roots. But where grown entirely in sphagnum moss, with free drainage, the evaporation proceeds so rapidly that there is little danger of over-watering. Where grown in a mixture of peat or osmunda fibre, some care is needed to avoid the compost becoming dry between the waterings, because of the risk of the foliage being affected by black spot,

ANGRÆCUMS belonging to the smaller-flowering section, which bloom during the winter and early in the spring, are best cultivated under the same conditions as that generally found suitable for Phalænopsis. The miniature growing kinds should have a position within reasonable distance of the roof glass. If grown in baskets or shallow pans, they are easily suspended from the roof. Careful watering is necessary at all times, and a close observation must be kept for thrips, scale, and other insect pests to which the plants are subjected.

RENANTHERAS.—There are several different species in cultivation, but the only one that is of service for exhibition and decorative purposes generally is R. Imschootiana. Until the last few years this species was very scarce, but now it is annually imported in large quantities, and plants are procurable for a modest sum. The brilliant scarlet flowers, produced on graceful racemes, are exceedingly useful, and, as the flowers last a long time in perfection, they are worthy of every consideration. A good amount of strong light is required during the winter and spring months. When growing, a highly humid hot atmosphere is necessary; but as the growing season is practically through the summer months, these conditions are easily provided. After the growth is completed, cooler conditions with less root moisture is desirable.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

EUCHARIS AMAZONICA.—Strong plants are now pushing up a good supply of flowering spikes, which will require very careful attention because of the preference black beetles and crickets have for the tender points. French beetle paste occasionally put down will clear the pests if persevered with for a few consecutive days. Copious supplies of diluted liquid manure from the farmyard and clear soot water may be used alternately with water. This will impart colour to the foliage, and generally improve the condition of the bulbs.

BEGONIA GLOIRE DE LORRAINE and its varieties are now producing an excellent floral display in the intermediate house. In order to prolong the season of blooming feeding should be continued. Light top-dressings of some good artificial fertiliser, and occasional waterings with well diluted liquid manure will be highly beneficial,

BEGONIA GLOIRE DE SCEAUX.—This excellent begonia presents a pleasing contrast to those of the Gloire de Lorraine type. The plants should by this date be set with flower buds, and the fact must not be overlooked that this begonia is an exceptionally gross feeder. The plants should have liquid manure occasionally, and be liberally supplied with water. Where these details are neglected the results will be disappointing.

EUPHORBIA FULGENS.—The plants of this elegant species are now developing their flowers and, as before stated, the flowering shoots are best kept as near the glass as possible without coming into contact with it until the blooms are fully expanded, after which they may with advantage be allowed to hang loosely for decorative purposes. Extreme care in watering is absolutely essential.—John Donoghue, Bardon Hill Gardens, Leeds.

FRUITS UNDER CLASS.

STRAWBERRIES IN POTS.—The first batch may be placed in a house in which a suitable temperature is maintained. See that the soil is free from worms and the foliage from red spider. If the presence of worms is indicated, turn the plants out of the pots, and remove them; should there be the slightest evidence of red spider, sponge the foliage with strong soft soap and sulphur. Then the surface soil should be loosened with the point of a stick and shaken away, and replaced with sweet fresh soil, containing a little soot. Strawberries must not be subjected to a high temperature at the commencement, Therefore, the forcing of these must be proceeded with quite slowly. A house or pit that is kept closed will be sufficient for the first fortnight, Royal Sovereign responds to early forcing very readily, and is deservedly popular. Other good varieties are Keen's Seedling and Vicomtesse Hericart de Thurry. The fruit of these are, however, small, but extremely sweet, and produced so freely as to require to be well thinned. Very little water will be required if the plants are syringed on fine days.

RIPE GRAPES.—Examine the bunches frequently and cut out the decayed berries, but, in doing so, be careful to avoid rubbing the bloom off. The long laterals of all vines may now be shortened still further, more especially those that come in contact with the glass. Use a little fire heat in dull weather, especially in the Gros Colmar, especially if the berries are not well coloured. This grape takes a rather long time to become well finished. In many private places I expect the Prince of Wales will supersede that variety. It is a handsome grape, and keeps well.

EARLY PEACHES.—The forcing of these must now be set about in earnest, and, assuming the trees have been pruned and properly trained, the house may now be closed, and no fire heat should be used during the first fortnight, except what may be necessary to keep the temperature up to 45 deg. The wood will be thoroughly ripened, and the trees, having had a good rest since cleaning should respond to a little additional warmth. Some growers prefer pot trees for the production of the very earliest supplies, and if these have to be secured from the nursery, only early and well approved varieties should be chosen. I have found Hale's Early one of the best, as the fruits set well, are large, handsome and well flavoured. Another favourite is Grosse Mignonne, which ripens about a fortnight later, and has handsome fruit of excellent flavour. Dymond succeeds this, and is one of the best, and a tree should be planted in each house.

LATE PEACHES.—The pruning and cleaning and training of these should be persevered with as circumstances permit. Old trees, as well as young, should be carefully pruned. An indifferent tree can often be made to present a smart appearance by skilful pruning and training. Proceed with the cleaning of the glass and woodwork as recently advised, for the early house, and if any pest such as scale or mealy bug exists on the trees, they must have a thorough washing with an approved insecticide.—W. A. Cook, Leonardslee Gardens

THE FLOWER GARDEN.

SUMMER-FLOWERING CHRYSANTHEMUMS.—A sufficient number of roots should now be lifted to provide a supply of cuttings for next season's stock of plants. The easiest plan is to place the roots in seed boxes, filling in with soil, and wintering them in an unheated frame. It is rather risky to allow the roots to remain in the open ground and rely on them for cuttings, for slugs play great havoc amongst the young shoots when under the surface of the soil. Those who do not possess a frame, will find an outhouse window a suitable place for a few boxes during the winter. The roots may be placed in the frames without boxes, but, at the same time, there is a greater advantage in boxing, for if cuttings are required early in February the roots can be readily placed where they will have a little warmth to accelerate the growth.

BORDER CARNATIONS. — The early planted layers will be quite established, and derive much benefit from having the surface of the soil stirred occasionally with the hoe. This operation should be carried out during dry weather, at the same time examining the plants, and if any are found to be loose they must be made firm again, In damp, low-lying districts, disease is often very prevalent at this season of the year, and affected plants should be given a dusting of air-slacked lime, which usually proves effective. A close guard must be maintained against the depredations of birds, rabbits, and hares. The lime will prevent the trouble caused by the birds, but for the other enemies wire netting must be fixed in position high enough to keep them off the beds,

SPRING BEDDING.—Wallflowers, shrubs, etc., which have recently been planted in the beds, and not yet become established, are often loosened by the rough autumn winds. Therefore it is necessary to examine them occasionally, and if found to be loose, the soil must be made firm about them. Violas, polyanthus and aubrietias, will require pressing down again after the first few frosts, which invariably lifts them a little. The leaves that accumulate about them should be removed to prevent any decay, and also to promote a tidy appearance. Give plants in vases in exposed positions a stake to afford them the necessary support. Lightly stir with a hoe when dry the surface of beds that are vacant.

LAWNS.—Give lawns a top-dressing of rich material, especially those on which the grass has become poor and mossy. A suitable top-dressing is composed of loam, well-decayed manure, and burnt garden refuse in equal parts. To this add a good proportion of soot, and mix the whole thoroughly and pass it through a sieve with a half-inch mesh.

ROCK GARDEN.—It is important that decaying foliage or fallen leaves be not allowed to remain about or over the plants. It is a point often overlooked in this department, and there is hardly anything likely to do more harm. The shelters which have been placed over various subjects should be examined, to see that the protection is efficient. Mice are usually troublesome, and must be looked after and destroyed as quickly as possible. Where the soil has been washed away from plants, it must be replaced at once.—E. C. Pooley, Gnaton Gardens, Plymouth.

Aster Climax.—It is now four years since this aster was given an Award of Merit by the Royal Horticultural Society, and time has proved that the honour was well deserved, for every year it gains many admirers. The flowers are large, of a pleasing shade of mauve, and disposed in long sprays, which are effective on the plants, and ideal for cutting purposes.—W. T.

EXHIBITIONS AND MEETINGS.

◆

Edinburgh Chrysanthemum Show.

The Scottish Horticultural Association held its annual exhibition in the Waverley Market, Edinburgh, on Thursday, Friday, and Saturday, November 16, 17, and 18. The exhibition was scarcely so extensive as usual, and the Scottish traders were not represented so widely as is the general rule. It was probably owing to this little lack of trade exhibits that one had the feeling that the show was not quite so good as usual; and, though this might hold good in the matter of extent, it did not in the matter of quality. Rarely have so many first-class exhibition blooms been seen together as on this occasion, and the long table that held the exhibits in the Edinburgh cup and Scottish cup classes was an exhibition in itself. Fruits were very well presented, the Scottish grapes and apples being excellent. Plants were fairly well displayed. The bush and specimen chrysanthemums being particularly good. Vegetables were good, and so, on the whole, were the floral decorations. But, alas! the weather was execrable. On the opening day a blizzard raged over the city, bringing with it sleet and cold rain; on the second day the rain fell in a quite determined manner all the time, and so we imagine the takings will have suffered. The arrangement of the competitive classes was very good, but the trade displays had to be set up in positions where the light was extremely bad. Mr. A. D. Richardson continues to act as secretary to the association, and we commend to the notice of other secretaries the beautiful legible writing upon the class cards and the painstaking repetition of full name and address in the case of competitors making numerous entries.

CUT FLOWERS.

The City of Edinburgh cup and £12 offered as first prize for fifteen varieties of Japanese chrysanthemums, three blooms of each, in vases, was won by Mr. T. Lunt, gardener to Captain A. Sterling, Keir, Dunblane, with a wonderfully fine clean set of flowers. The varieties and their points (12 as a maximum for three blooms) were: Hon. Mrs. Lopes, 10½; E. Jamieson, 10; Mrs. L. Thorn, 10½; Mrs. Pearson, 10; F. S. Vallis, 10½; Reg. Vallis, 10; Mrs. A. T. Miller, 11; D. B. Crane, 10½; G. Hemming, 10; Purity, 11; Lady Letchworth, 10; White Venosta, 9½; Mrs. F. W. Vallis, 10½; Bessie Godfrey, 10½; and White Queen, 11½; a total of 156 out of a possible 180. There were six competitors, and second prize fell to Mr. Jas. McKellar, gardener to J. Jameson, Esq., J.P., St. Marnocks, Co. Dublin, who totalled 140½ points out of a possible 180; Mr. G. Stewart, gardener to Sir James Sevewright, Tulliallan Castle, Kincardine, third with 139 points; Mr. L. McLean, gardener to David Thomson, Esq., Greenfield, Alloa, fourth with 132½ points, his White Queen gaining 11 points.

The Scottish challenge cup competition, open only to Scottish gardeners and amateurs, brought out seven competitors, and the famous cup, with its cash award, was finely won by Mr. Robt. Honeyman, gardener to Wm. Ramsay, Esq., Bowland, Stow, with as superb a set of eight vases as has been staged for a good while. In depth, width, form, and colour, there was little lacking, and if the judges had pointed higher than they did scarcely anyone would have found fault. The varieties and points were as follows: Lady Talbot, 11½; Mrs. A. T. Miller, 11½; Hon. Mrs. Lopes, 11; Mary Poulton, 11 (one bloom in this vase was regarded as the best in the show); Mrs. F. W. Vallis, 11; Mrs. L. Thorn, 11½; Algernon Davis, 10; and Purity, 11½; total, 89 out of a possible 96. Second prize was won by Mr. J. Small, gardener to J. Graeme Thomson, Esq., Norwood, Alloa, with a total of 78 points; Mr. R. Mackenzie, gardener to Jas. G. B. Baillie, Esq., Dochfour Gardens, Inverness, third, with 77½ points; and Mr. Jas. Finnie, gardener to A. R. Brown, Esq., Summerhill, Shandon, fourth, with 74½ points.

The competition in the class for six vases of Japanese varieties was very keen, seven entering. The first prize was won by Mr. R. Honeyman with beautiful examples of Mrs. A. T. Miller, Mdme. P. Radaelli, Lady Talbot, Hon. Mrs. Lopes, and Edith Jamieson; Mr. J. Small came second, and Mr. H. MacSkimming, gardener to W. T. MacLellan, Esq., Auchenraith, Helensburgh, third. For two vases of one variety, Japanese, Mr. Jas. McKellar led with five specimens of Frances Jolliffe.

For a dozen Japanese blooms on boards, Mr. Thos. Lunt was to the front again with a very even set of fresh flowers, practically all of the gracefully reflexing and semi-drooping habit. The varieties were Mrs. C. G. Kelly, Purity, Melchett Beauty, Hon. Mrs. Lopes, E. J. Brooks, F. S. Vallis, Mrs. F. W. Vallis, Bessie Godfrey, White Venosta, D. B. Crane, T. Chandler, and White Queen. Mr. Jas. Small, Alloa, won second prize, and Mr. R. Mackenzie third.

Mr. J. Waldie, gardener to W. H. Dobie, Esq., Dollarbey, Dublin; Mr. J. Loan, gardener to J. H. Younger, Esq., Bughtrigg, Coldstream; Mr. A. Gauld gardener to Mrs. Robert Procter, Claremont, Alloa, Mr. Lunt, and Mr. Mackenzie, were leading prizewinners in other vase classes for Japanese chrysanthemums. For a new Wells-Pockett novelty of 1911, Mr. R. Mackenzie won the prize with William Turner; Mr. R. Whannell second with the same variety; and Mr. J. E. Davis third. The best new chrysanthemum, was Pockett's White Australia, exhibited by Messrs. W. Wells and Co., Merstham, Surrey, a graceful white flower, and secured the silver medal.

A gold medal and cash were offered as the first prize for half a dozen vases of single chrysanthemums, twelve sprays in a vase, and this attraction secured four entries. The leading prize was won by Mr. W. G. Pirie, gardener to C. W. Cowan, Esq., Dalhousie Castle, Bonnyrigg, with fine disbudded blooms of Sylvia Slade, Willie Smith, Purity, Altrincham Yellow, Mary Richardson, and Edith Pagram; Mr. W. Galloway, gardener to the Earl of Wemyss, Gosford, Longniddoy, came second; and Mr. Adam Knight, gardener to Sir Wilfrid Lawson, Bart., Brayton, Carlisle, third. For three vases of single varieties, Mr. R. Honeyman triumphed with Altrincham Yellow, Purity, and Willie Smith in grand condition; Mr. Alex. McMillan, gardener to the Earl of Home, Douglas Castle, Lanark, second; and Mr. R. Whannell, gardener to Colonel More Nesbett, The Drum, Gilmeston, third. In another three-vase class Mr. W. G. Pirie scored, followed by Mr. Galloway and Mr. McMillan. Mr. A. Brydon, Tweedbank, Inverleithen, had the best vase of single chrysanthemums, winning with a fine vase of Sylvia Slade.

So far as we could gather there was but one exhibitor of six vases of chrysanthemums as grown for market; this was Mr. James Bruce, Springfield Nursery, Davidson's Mains, whose leading varieties were Felton's Favourite, Edith Pagram, Mary Richardson, and Bronze Soleil d October. Mr. Davidson led for a vase of decorative chrysanthemums with Parson's White; Mr. R. Jenner, Stirling, second.

Perpetual carnations were grandly shown by a few amateurs in a class for two vases of blooms. Mr. A. Williams, Tidley, was first; Mr. A. McKinven, Carlebank, Lanark, second; and Mr. J. Wilson, Montague Gardens, Leven, Fife, third.

FLORAL DECORATIONS.

These were a prominent and attractive feature. Miss Newlands, Bridge Street, Leith, won first prize for one bride's and two bridesmaids' bouquets, the latter composed of pink roses and lily of the valley, the former of odontoglossums, white carnations, and lily of the valley. Mr. A. Knight led for a bouquet of carnations, and Mrs. W. L. Boase, Binrock, Dundee, had the best orchid bouquet, composed of cattleyas and odontoglossums; Mr. A. Knight, second. Mr. J. Hood, Dalmore, Helensburgh, had the best bouquet of chrysanthemums, an arrangement of dull yellow and bronze flowers, with croton leaves and berberis foliage. Miss Burton, New Langton Hall, Polton, was to the front for a basket of chrysanthemums, with Mr. G. Scott, Seathwood Gardens, Dundee, a close second with big Japanese flowers pleasingly associated with those of single varieties. For a basket of flowers, any kinds, Mr. A. Knight scored in a poor competition with oncidium sprays and lily of the valley. Mrs. Boase had the only wreath, and was awarded first prize.

The best basket of hardy foliage and berries was adjudged to be the large one arranged by Mr. J. Hood, gardener to T. G. Bishop, Esq., Dalmore, Helensbrugh, who used sprays of golden privet, variegated hollies, and euonymus, with rose hips, oak apples, holly, and privet and pernettya berries; Mr. D. Kidd, gardener to Lord Elphinstone, Carberry Towers, Musselburgh, second, and Mr. F. Cowe, Carris Eskan, Musselburgh, third; eight entries.

Five baskets of orchids and suitable foliage were staged, and the chief prize was won by Mr. D. Halliday, gardener to W. Mackay, Esq., Ascog, Bute, with a fine display of Cattleya labiata, C. Trianæ, calanthes, cypripediums, oncidiums, and cymbidiums; second prize fell to Mr. J. Clark, gardener to F. S. Roberts, Esq., Bannerfield, Felkirk, for a rather heavy arrangement of odontoglossum sprays over cattleyas—the flowers were by no means made the most of; Mr. Duncan Mackay, gardener to C. Dickson, Esq., Viewbank, Lasswade, was third with cattleyas, odontoglossums, and dendrobiums.

In the class for a large vase of chrysanthemums arranged with suitable foliage, three huge arrangements were staged, and the best was from Mr. D. Kidd, who had about thirty large Japanese blooms, associated with sprays of scarlet oak crotons and larch; Mr. A. McMillan came second, and Mr. G. Scott, Seathwood, Dundee, third. Three vases of chrysanthemums and suitable foliage found Mr. W. Galloway to the front with Felton's Favourite, La Triomphante, and Bronze La Triomphante; Mr. J. Beates, gardener to Mrs. Boase, Dundee, second, and Mr. A. Osydon, third; there were eight entries in this class.

FRUITS.

Fruits were capitally shown, and the competition appeared to be fairly keen throughout the numerous classes.

Three collections were staged in the class for eight kinds, and here Mr. D. Kidd was to the front with Lady Downes and Gros Maroc grapes and splendid dishes of Peasgood's Nonsuch, Baumann's Red Reinette, and Emperor Alexander apples, and Beurre Diel, Doyenne du Comice, and Pitmaston Duchess pears; Mr. W. Galloway, Gosford, was second, showing fine Appley Tower grapes, and Emperor Alexander apples. Mr. G. Pirie annexed the first prize for four bunches of grapes with neat well-finished clusters of Gros Colmar, Alicante, Muscat of Alexandria, and Cooper's Black; Mr. W. Kidd second, and Mr. D. Halliday third.

For two bunches, one each of a black and a white variety, Mr. W. Campbell, gardener to Colonel Stewart Mackenzie, Braham Castle, Cononbridge, was a capital first with Muscat of Alexandria and Black Morocco; Mr. W. Galloway second, and Mr. W. E. Pirie third. Mr. Pirie scored for a pair of bunches of white grapes; Mr. D. Halliday led for two bunches of Alicante with big bunches of deeply coloured berries; eleven entries. For Gros Colmar Mr. Jas. McNeill, gardener to Major Thorburn, Craigerne, Peebles, was first, with big plum-like fruits; six entries. A little humour entered into this competition, because one, evidently hurried, competitor had attached a card for "three stalks of Brussels sprouts" to his grapes. Mr D. Kidd had the best bunches of Lady Downes grapes. Mr. J. McNeill scored for a bunch of Lady Hutt, Mr. J. Law, Dirleton, for one bunch of Apply Towers; Mr. J. McNeill led for "any other grapes."

Mr. Galloway came to the front for six dishes of pears, Scottish grown, Glou Morceau, Hacon's Incomparable, and Duchess d'Angoulesse being his best dishes; Mr. R. Sinclair, Congalton Gerdens, Drem, second, and Mr. R. Pow, Saltoun Hall Gardens, Pencailtond, third. In the open class for six dishes of pears, Mr. R. Currie, Foxley Hall, Hereford, was to the front, and he showed Beurre Diel and Doyenne du Comice well; Mr. W. Galloway second, and Mr. G. Mackinlay, Wrest Park Gardens, Ampthill, Bedford, third.

A grand lot of fruit, shown by Mr. James Duff, gardener to Colonel Gordon, Threave House, Castle Douglas, won first prize for eighteen varieties; a few of the best dishes were Cox's Pomona, Allington Pippin, Cellini, Bramley's Seedling, Lady Henniker and Peasgood's Nonsuch; Mr. G. Mackinlay was a good second, and Mr. R. G. Sinclair, Drem, third.

In the Scottish class for eighteen dishes of apples, Mr. Duff was again chief prize winner, and here again he showed fine fruits of King of the Pippins, Bismarck, Allington Pippin, Cox's Pomona, Alfriston, Castle Major, Newton Wonder, The Queen, and Peasgood's Nonsuch; Mr. R. G. Sinclair second, and Mr. A. Dickson, Glenormiston, Innesleithen, third; seven competitors. Mr. Duff was also to the fore in the open class for six dishes of culinary apples, followed in order by Mr. R. Currie and Mr. C. Webster, gardener to the Duke of Richmond and Gordon, Gordon Castle, Fochabers. Mr. Chisholm, gardener to the Marquis of Lansdown, Meikleour House, Meikleour, had the best set of six dishes of dessert apples, winning with Gascoyne's Scarlet, Jas. Grieve, Worcester Pearmain, American Mother, Wealthy, and Allington Pippin; Mr. R. Currie second, and Mr. G. Mackinlay third.

Mr. J. Harris, Silsoe, Bedford, scored for three baskets of dessert apples, ready for market, with good samples of King of the Pippins, Fearn's Pippin, and Blenheim Pippin; Mr. J. McKenzie, Lochend Gardens, Dunbar, led for three baskets of culinary apples.

PLANTS.

There was a quite good array of large specimen bush-grown chrysanthemums. Mr. W. Pullman, gardener to D. R. Hine, Esq., Colinton Road, Edinburgh, had a fine set of six plants in seven-inch pots, his Souv. d'Un Petite Ami being especially good; he secured first prize in close competition. Mr. W. Michie, gardener to Lady Steel, Boroughfield, Edinburgh, had the best specimen of a large-flowered variety—Souv. d'Un Petite Ami, with about three dozen blooms. For two specimens Mr. Michie was first, and he also scored for four specimens with a fine set, and was here followed by Mr. Pullman and Mr. J. Fraser. In the class for six specimens, Mr. W. Pulman led with very fine examples of Mrs. Greenfield, Cheltoni, Nellie Pockett, Wm. Duckham, Mrs. W. Reid, and Swanley Giant; Mr. Michie was second with good but somewhat smaller specimens. Mr. A. McMillan had the best three pans of lily of the valley, and also the best four nerines. Mr. J. Alexander, of Craigmillar, scored for scarlet salvias, and Mr. J. Templeton, Richmond House, Glasgow, showed the best foliage plants.

Mr. C. Shaw, gardener to S. Mitchell, Esq., Boquhan, Kippen, led for four begonias with big spreading bushes of Gloire de Lorraine varieties; Mr. D. McLean, Raith, Kircaldy, second; and Mr. A. Williams, gardener to Lord Stratheden and Campbell, Jedburgh, third; eight entries.

VEGETABLES.

Leeks were wonderfully good, but not thick enough for those champion growers, the Tyneside colliers; there were a dozen sets of eight, and Mr. Adam Brydon had the best set. Out of twenty-five entries Mr. J. J. Staward, gardener to R. M. Pilkington, Esq., St. Fort House, Fife, led with fine produce. Mr. J. Paterson, Rutherford, Roxburgh, was ahead for six heads of celery; and Mr. W. Douglas, Easter Duddingstone, Portobello, was to the front for a dozen bunches of market-grown leeks. Mr. J. J. Staward scored for six cauliflowers with neat close heads, from sixteen competitors. Curled kale, savoys, and cabbages were all finely shown, and beets were good. Parsnips were wonderfully clean and long for the season, and Mr. D. Pett, Kelso, was first prize winner. Mr. C. Shaw scored for onions, and Mr. Davidson for carrots, each in a strong competition. Mr. W. P. Bell, Bothwell Castle Gardens, was ahead for potatoes.

Three competitors came forward in the class for nine kinds of vegetables, and each showed fine produce in capital style. Mr. Robert Steward, gardener to Lord Lauderdale, Thirlestone Castle, Louder, was first prizeman; Mr. F. Urquhart, gardener to H. Mungall, Esq., Gattonside House, Melrose, second; and Mr. W. P. Bell, Bothwell Castle Gardens, third.

NON-COMPETITIVE.

Messrs. W. Wells and Co., Merstham, gained a gold medal for their attractive exhibit of chrysanthemums, mostly new varieties, and carnations. A few of the new sorts were Mrs. Gilbert Drabble (31 inches in circumference in one instance), represented by six grand flowers; Josephine, a yellow single; Miss L. Hall, a pink Japanese; and the brightly-coloured Mrs. R. H. Witty. The group also included a selection of up-to-date single and decorative varieties, the whole producing a brilliant effect. Messrs. Storrie and Storrie, Glencarse, filled two tables with an interesting collection of apples, arranged under pyramidal specimens of celosias (gold medal).

Carnations from Messrs. W. Cutbush and Son, Highgate, made up a goodly group, The President, Scarlet Glow, and Rose Dore being especially attractive. Dr. McWatt, Morelands, Duns, displayed a very interesting collection of primulas, and had a flower P. obconica in variety, P. floribunda, P. f. Isabellina, P. molacoides, P. Kewensis, P. Forbesi, P. f. rubra, P. capitata, P. denticulata, P. megasæfolia, P. decora alba, P. Palinuri, P. frondosa, P. Poissoni, P. chenessis, and primroses and polyanthuses—a very interesting group.

Messrs. Young and Co., Cheltenham, had a very charming exhibit of perpetual carnations, including Duchess of Devonshire and Lady Audley Neild in fine condition. Messrs. Sutton and Son, Reading, showed a splendid collection of vegetables, and, as usual, set up excellent produce in a most attractive manner; leeks, onions, carrots, tomatoes, cucumbers, cauliflowers, artichokes, and Hero of Lockinge melons (fruits, by the way), were very fine (gold medal).

Messrs. John Forbes, Lim., Hawick, were represented by perpetual carnations, Michaelmas daisies, bamboos, etc. Messrs. Dobbie and Co., Edinburgh, had a circular table of decorative and single chrysanthemums. The largest exhibit was from Messrs. Dicksons, Waterloo Place, and consisted of a big bank of single chrysanthemums, in masses of popular varieties like Narcissus, Mary Anderson, Mary Richardson, Kitty Bourne, Altrincham Yellow, Elsie Hill, Metta, Mensa, and Florrie Stevens, etc. (silver gilt medal).

Newcastle Show and Northern Fruit Congress.

The North of England Horticultural Society joined forces with the Newcastle Chrysanthemum Society on November 15 and 16, and a splendid show was held in the Town Hall and Corn Exchange, while the Conference part of the proceedings was held at the Mining Institute on the first day, and at the Town Hall on the second day.

The chrysanthemum show was a great success, flowers and plants being alike excellent, but all suffered somewhat from lack of space. Mr. Musk's cut blooms were superb, while the bush plants were a revelation. The fruit show section was arranged in the upper hall, and this, too, was a great success, the fruit staged being of a very high quality and showing a good deal of colour; the competition was first rate.

The conference proceedings were not very well attended, but we do not attach too much importance to numbers in such a case as this, for provided the matters dealt with are of importance and put forward interestingly, a vastly larger public than that hearing the lectures is sure to be appealed to and reached. In our judgment the programme was too extensive, and the sessions followed on each other too closely. There were three sessions and five lectures each afternoon.

There were numerous delegates from the North of England Horticultural Society present, and representatives from the County Councils in the South of Scotland, while Mr. F. J. Chittenden and Mr. J. Hudson, V.M.H., represented the Royal Horticultural Society. The arrangement of affairs fell chiefly in the able hands of Mr. W. Marrison and Mr. F. Fox, the secretary and chairman of the Newcastle, and the Rev. Bernard Hall, secretary of the N.E.H.S.

On Wednesday, November 15, the proceedings were opened by Lady Grey in the presence of a large attendance of the nobility and gentry of the district, under the presidency of the Lord Mayor, Sir W. H. Stephenson. The attendance at the exhibition was very good, and we understand that the takings at the gate were in excess of last year.

CUT FLOWERS.

These were particularly fine, and, staged in vases, they produced a capital effect.

There were six competitors in the open class for not less than a dozen Japanese varieties, three blooms a vase, the chief award being Mr. Henderson's silver cup and £5. The leading honours fell to Mr. G. W. Musk, gardener to Captain J. F. Laycock, Wiseton, Notts, for large, beautifully fresh flowers of Mrs. R. H. B. Marsham, Mrs. F. C. Stoop, Master David, Rose Pockett, F. S. Vallis, Marquis of Northampton, G. F. Bruzzard, Reg. Vallis, Leslie Morrison, Master James, Mrs. A. T. Miller, Mrs. W. Knox, Eclipse, Sir F. Crisp, and J. Lock. Second prize was won by Mr. R. Addison, gardener to the Countess of Ravensworth, Creswell Hall, Morpeth, and third by Mr. H. Smith, gardener to R. D. Marshall, Esq., Castlerigg Manor, Keswick.

There were five good entries of six Japanese varieties, three blooms of each, in vases, and here Mr. G. W. Musk was again first with flowers of very fine form and quality; Mr. A. W. Appleton, gardener to C. Lacy Thompson, Esq., Farlam Hall, Brampton, second, and Mr. H. Smith, Keswick, third.

Mr. G. W. Musk scored for four vases, three blooms in each, of Japanese varieties, and he was followed in order by Mr. H. Smith and Mr. A. W. Appleton, in a keen competition. Mr. Musk was to the front for three white Japanese blooms, with grand specimens of Mrs. R. T. Miller, and he led for three flowers of a yellow variety with F. S. Vallis. For four vases and for two vases respectively of incurved varieties, Mr. Musk was all alone, and he showed large solid flowers. Mr. Musk continued his conquering way in the class for six vases of single varieties with beautiful bunches of Altrincham Yellow, Bronze Pagrom, Mary Anderson, etc.; Mr. T. Swan, gardener to H. A. Murton, Esq., Bertley Hall, Durham, second, and Mr. T. Percy, gardener to J. Readhead, Esq., Westoe Hall, South Shields, third. For decorative blooms six vases and as many varieties, Mr. O. Brown led the way, with Mr. Musk a very close second.

Other leading prize winners for cut flowers were Mr. Thomas Bell; Mr. J. Hall, gardener to Mrs. Hunter, The Grange, Whickham; Mr. J. Kew, gardener to Dr. Simpson, Bradley Hall, Wylam; Mr. J. Arken, gardener to the Right Hon. W. Runciman, Esq., M.P., Doxford; and Mr. R. Addison, Cresswell Hall Gardens, Morpeth.

PLANTS AND GROUPS.

Bush plants were largely shown, and were so fine that they constituted a feature of unusual interest. For four specimens in not fewer than two varieties Mr. W. Thompson, 39, Aston Street, South Shields, won first prize with wonderful specimens of Viviand Morel (2), J. B. Bryce, and Nellie Pockett. Second prize fell to Mr. Thomas Reay, Westoe Hall Gardens, South Shields, for Viviand Morel, Charles Davies, etc.

Mr. Thompson scored for three bush plants of Japanese varieties; Mr. J. Cooper, Westoe Parade, South Shields, was second, with Viviand Morel in good form, and Mr. C. Prince, Mortimer Road, South Shields, came third. The bushes of single varieties were also fine, and Mr. Frost, Gordon Street, won first prize. Mr. Thompson led for two pompon specimens, with huge examples, but all the entries in this class were crowded owing to lack of room; Mr. C. Prince second, and Mr. R. Frost third.

Premier award for a large miscellaneous group was won by Mr. Thomas Bell, gardener to A. E. Bambridge, Esq., Lynwood, Jesmond, with a pretty display, consisting of single and decorative chrysanthemums, palms, crotons, begonias, cattleyas, Cypripedium insigne Sanderæ, marantas, etc.; second prize fell to Mr. J. Hetherington, gardener to C. T. Kendall, Esq., Preston Hall, South Shields, whose begonias and chrysanthemums were the chief flowering plants.

FRUIT SHOW.

The fruit show section of the show was under the auspices of the North of England Horticultural Society, and the Rev. Bernard Hall, the secretary, lent his valuable aid here, and also, we believe, engineered the conference on educational matters and fruit culture. The competition was almost entirely confined to growers in the four northern counties, and in the class for a dozen dishes of hardy fruits the leading prize was a challenge cup presented by Mr. J. H. Straker, Howden Dene, Corbridge, and 20s. This was won by Mr. J. Cocker, Chester, with excellent dishes of Beurre Bosc, Beurre Diel (two dishes of wall fruits) pears, and Charles Ross, Peasgood's Nonsuch (two dishes), Blenheim Pippin, Lane's Prince Albert (two dishes), Emperor Alexander, Lord Derby, and King of Tomkin's County apples. Mr. H. E. Lloyd, St. Wilfred's Road, Hexham, came second, and his best dishes were of Warner's King, Allington Pippin, and Cox's Orange Pippin apples; third prize fell to Mr. J. M. Robson, gardener to C. A. Harrison, Esq., Beacon Grange, Hexham.

The Noss Cup for nine dishes of culinary apples and three dishes of dessert varieties brought out four competitors, the premier position being taken by W. Alexander, Esq., J.P., Long Close, Hexham, with good examples of Alfriston (two dishes), Royal Jubilee, Warner's King, Bismarck, Lord Derby, Newton Wonder, King of the Pippins, Worcester Pearmain, Lane's Prince Albert, Bramley's Seedling, and Cox's Orange Pippin; Mr. E. Tindale, gardener to Lord Ravensworth, Gateshead, was a capital second, and Mr. J. T. Stewart, gardener to Colonel Salfield, Holm Hill, Dalstone, third.

For six cooking and three dessert varieties of apples, the premier award was the Alexander cup, and this fell to W. Alexander, Esq., J.P., for capital dishes of Lord Derby, Ecklinville, Warner's King, Bismarck, Newton Wonder, Bramley's Seedling, Cox's Orange Pippin, King of the Pippins, and Worcester Pearmain; Mr. W. Lovett, gardener to A. B. Collingwood, Esq., Lilbrim Towers, Alnwick, a capital second; and Mr. H. Lambert, gardener to Earl Grey, Howick, Lesbsbury, third, with smaller, brightly coloured fruits; seven entries.

The unusual and magnificent prize of five guineas was offered for the best six dishes of culinary apples by Mr. N. Naylor; the second prize was 15s., and the third 10s. There were fourteen entries, and the big prize was won by W. Alexander, Esq., Long Close, Hexham, with fine specimens of Lord Derby, Warner's King, Bramley's Seedling, Alfriston, Bismarck, and Newton Wonder; Mr. G. Pattison came second, and Mr. Millican, Scotby Lane, Scotby, Carlisle, third.

In the single dish classes Mr. W. Alexander scored for Newton Wonder; Mr. H. Lloyd for Lane's Prince Albert; Mr. T. Simpson, Hepscott, for Peasgood's Nonsuch; Mr. J. T. Stewart for a locally-raised culinary apple with an unnamed dish. Mr. Alexander also scored for three dishes of culinary apples (first prize three guineas), with Lord Derby, Bramley's Seedling, and Warner's King; Mr. F. J. Sage, gardener to W. J. Sanderson, Esq., East Field Hall, Wartsworth, second; and Mr. J. Henderson, gardener to the Right Hon. Sir E. Grey, Falloden Hall, Northumberland, third; nineteen entries.

For dessert apples, three dishes, there were twenty entries, and Mr. W. Gentles, gardener to Sir H. D. Blackett, Bart., Malfen Hall, Corbridge, scored with Allington Pippin, Lamb Abbey Pearmain, and Cox's Orange Pippin; Mr. D. Millican, Scotby, second; and Mr. Alexander had to be content with third place. First prize for a dish of Bramley's Seedling was secured by Mr. T. Simpson, with a capital dish, from eleven competitors. Mr. J. T. Stewart had the best dish of King of the Pippins. Mr. E. Tindale led for two dishes of pears, wth Doyenne du Comice and Catillac; Mr. W. Smith second, and Mr. J. Snell, Close House, Wylam, third. Mr. W. Smith had the best dish of pears—Beurre Diel—and Mr. Simpson was second.

First prize for white grapes fell to Mr. Thos. Bell, gardener to A. E. Bainbridge, Esq., Lynwood, Jesmond, who had very finely coloured Muscat of Alexandria; Mr. W. Smith, gardener to the Earl of Durham, Lambton Castle, second with the same variety; and Mr. W. H. Stabler, gardener to E. Joicey, Esq., Whinney House, Low Fell, third with Golden Queen. Out of ten entries of black grapes, two bunches, Mr. W. Smith scored with Gros Colmar in first-rate condition; Mr. J. Hetherington, gardener to C. T. Kendall, Esq., Preston Hall, North Shields, second, with Alicante; and Mr. O. Brown, gardener to Mrs. N. J. Robinson, Preston Towers, North Shields, third.

A capital bunch of bananas (Musa Cavendishi) was exhibited by Mr. Edward Keith, gardener to Sir G. O. Trevelyan, Bart., Wallington, Morpeth; it was a grandly-grown bunch, and, shown with its stem and leaves, it made a very attractive item.

NON-COMPETITIVE.

No show of any pretensions is complete nowadays without its complement of non-competitive exhibits. At Newcastle the trade showed well, although limits of space necessarily rather cramped their efforts.

Mr. W. Lawenson, Yarm-on-Tees, contributed an attractive exhibit of chrysanthemums, heaths, bouvardias, begonias, cyclamens, etc., attractively disposed with ferns and palms. Messrs. Michie and Co., Alnwick, had a most interesting collection of apples collected from various parts of Northumberland, Durham, and Yorkshire, and the dishes of Newton Wonder, Bramley's Seedling, Gloira Mundi, Mere de Menage, Catshead, Lady Henniker, Warner's King, King of the Pippins, and Peasgood's Nonsuch were splendid, and gave evidence of what the northern counties can do.

Messrs. Dicksons, Chester, contributed a bank of chrysanthemums, and the single yellow Mrs. Henry Perkins, largely shown, was the chief attractiont. A particularly fine exhibit from Messrs. Kent and Brydon, Darlington, included grand sheaves of Lilium longiflorum, L. speciosum, and L. auratum alternating with stands of decorative chrysanthemums, and with a foreground of perpetual carnations, lily of the valley, and apples. Messrs. Clibran, Altrincham, presented an attractive exhibit of finely-grown vegetables.

Wm. Fell and Co., Hexham, made up a very interesting exhibit of northern-grown apples, together with choice ferns, and a selection of perpetual carnations. Messrs. Joseph Robson and Son, Hexham, presented dwarf evergreen shrubs, and a collection of apples. Messrs. Stuart and Mein (now incorporated with Messrs. Laing and Mather), Kelso, showed a goodly set of apples and seed potatoes.

From the experimental grounds, Northumberland, came a considerable collection of apples, the fruits bright and clean but somewhat small. Spraying machines and syringes from the Four Oaks Company, Birmingham, attracted a great deal of attention, as also did the Jeyes' insecticides. Other exhibitors who contributed to the interest or attractiveness of the show were Messrs. W. J. Watson, Lim., Newcastle; Messrs. Finney, Newcastle; Mr. J. H. Evans, Newcastle; Mr. W. R. Armstrong, Newcastle; Messrs. W. F. Bamshaw and Co., Sunderland, etc.

MEDALS.

Gold.—To Messrs. Clibrans, Altrincham; and Messrs. Kent and Brydon, Darlington.

Large Silver-gilt.—Messrs. W. Finney and Co., Newcastle; Mr. W. Laweasen, Yarm-on-Tees; Messrs. Laing and Mather, Kelso.

Silver Gilt.—To Messrs. Miche and Co., Alnwick; and Mr. Musk, gardener to Captain G. F. Laycock, Wiseton, Bawtry, Notts.

Large Silver.—To Mr. H. Evans, Newcastle; Messrs. W. Fell and Co., Hexham; Messrs. Mack and Miln, Darlington.

Silver.—The Four Oaks Company, Sutton Coldfield; Messrs. Ramshaw and Co., Sunderland; Messrs. J. Robson and Son, Hexham; Messrs. W. J. Watson, Lim., Newcastle; Mr. Chisholme, for the Northumberland Experimental Farm.

Large Bronze.—To Mr. W. R. Armstrong, Newcastle; Messrs. Dicksons, Lim., Chester; Messrs. H. Walker and Son, Newcastle.

Bronze.—Messrs. Porteous and Thomson, Hexham.

Highly Commended.—Messrs. W. Cooper and Nephew, Berkamsted; Jeyes' Sanitary Compound Company, London; Messrs. A. McLauchlin and Co., Stranraer; Messrs. W. Voss and Co., Millwall, London.

The foregoing awards were all granted by the North of England Horticultural Society.

VEGETABLES.

Some marvellous leeks were shown, chiefly by the Tyneside colliers, and their carrots, parsnips, and celery. For a collection of vegetables Mr. R. Shield, Waterside Cottage, Swalwell, was first with fine produce a trifle on the long side.

Bournemouth Gardeners' Association.

A very interesting lecture was given by Mr. Harris, of Osborne House, Bournemouth, before the members of the above association at the last fortnightly meeting. His subject was: "Will the French Intensive Culture System become Popular in England?" From the first the lecturer took the negative view, but at the same time he very ably and fairly reviewed the system as followed in France, and said that cultivators there had got used to it, as son had followed father for generations. We, in this country had plenty of coal, and so made use of heating apparatus to a large extent, while in France coal was scarce, but straw being cheap and plentiful, there was ample material for making hotbeds. Straw in England was not plentiful, and consequently it was dear and not obtainable in large quantities for hotbeds. In France cultivators relied chiefly upon cloches and hotbeds, whereas we used hothouses and hotwater apparatuses and grew grapes and more expensive kinds of fruits and fewer vegetables and salads in a forced condition than did our neighbours across the channel.

At the close of the lecture a very good discussion took place amongst the members, and Mr. Harris replied to some questions. It was generally felt by the members that, in this country, the French system would only be followed as a supplement to our spring forcing by hot water in private gardens, and that such a system had been practised for generations. When first boomed a few years ago, many inexperienced persons took it up, and, in nearly all cases, with disastrous results.

Mr. C. Nippard, gardener to J. J. Norton, Esq., staged some lovely dessert apples, and a fine Begonia Turnford Hall. Mr. C. Pearce had a nice display of cut chrysanthemums. Both the lecturer and Mr. E. G. Cox, the chairman, received hearty votes of thanks.

THE GREAT WINTER SHOW
will be held in
THE ROYAL BOTANIC GARDENS.
on
DECEMBER 5 and 6, 1911.
Admission 1s.
Schedules and particulars from
E. F. HAWES,
Imperial School of British Horticulture, West Hampstead, N.W.

Royal Horticultural Society.

Not only was there a large and brilliant display of plants and flowers at the Royal Horticultural Hall, on Tuesday, November 21, but practically every inch of available space was occupied. The attendance was large during the afternoon. Chrysanthemus, orchids, and winter-flowering begonias, ferns, carnations, and apples were the chief features of the meeting. The Orchid Committed granted no fewer than five First Class Certificates and three Awards of Merit, while the Floral Committee granted eleven Awards of Merit, and the Fruit Committee one Award of Merit.

FLORAL COMMITTEE.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, filled the end of the hall with a splendid exhibit of chrysanthemums set up in big stands or large vases of a variety. It was a great effort, and carried out with that artistic skill one associates with the Ryecroft displays. Autumn-coloured foliage, crotons, palms, and ferns were all freely used with and among the flowers. Notable Japanese varieties staged were Frances Joliffe, Mrs. F. S. Vallis, Ada Hutchingham, Glaucus, Ernest G. Mocatta, Mrs. R. H. B. Marsham, Mary Hollert, Mrs. A. E. Roope, and Mdme. Magne. Decorative, single and incurved varieties were also freely staged.

A large and interesting display of single chrysanthemums, from Mr. Edwin Beckett, gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, was a great attraction; there were about seventy large bunches, well set up on a long table, and these represented about seventy varieties. A few of special attractiveness were Mary Richardson, R. C. Pulling, Charles Kingsley, Acme, Mary Anderson, Scarlet Gem, Mensa, Metta, Miss Mary Pope, Wordsworth, Mrs. R. M. Parkinson, and Canopas.

A whole table was filled by Messrs. H. B. May and Sons, Edmonton, with a grand collection of over eighty species and varieties of davallias. There were several dozen huge specimen plants of these fine ferns, besides a large number of small plants. Prominent among the sorts displayed we noticed D. figiensis plumosus, D. tennifolia Veitchi, D. elegans, D. dissecta, D. polyantha, D. Mooreana, D. pentaphylla, etc. The plants were all beautifully grown, and well merited the high award granted.

The chrysanthemums from Mr. W. J. Godfrey, Exmouth, included a very useful anemone-flowered variety named Godfrey's Perfection; this is white, very free flowering, long keeping, and altogether an excellent decorative sort; Godfrey's Crimson, and Sir Frederick, a ruby-crimson single, were other prominent varieties from Exmouth. Mr. Vincent Slade, Taunton, made a bright show with single and semi-double zonal pelargoniums. Mrs. V. Slade and the double Paul Crampel were notably good.

A good exhibit of chrysanthemums, finely set up by Messrs. W. Wells and Co., Merstham, commanded attention and admiration. Great masses of big blooms were grouped in stands, and beautiful singles and decorative sorts were arranged tastefully in vases. In the centre there were several dozen flowers of the splendid white Japanese variety Mrs. Gilbert Drabble, with the beautiful Wm. Turner in close association; baskets and stands of Mrs. W. Higgs, Mensa, Metta, Ceddie White, Josephine, and Ceddie Mason, all good singles, made good flanking parties, while Mrs. W. H. Reid, Miss A. Brooker, Jack, Chas. Dickens, Caledonia, R. F. Felton, and Lady Carmichael were other specially fine varieties. Palms, ferns, crotons, etc., were pleasingly associated with the fine flowers to produce a splendid effect.

Mr. Jas. Box, Lindfield, contributed a group of single chrysanthemums, and Messrs. Jas. Veitch and Sons, Chelsea, presented a large bank of these useful flowers, together with a few decorative and big show blooms.

A large table of winter-flowering begonias from Mr. A. Allan, gardener to Lord Hillingdon, Hillingdon Court, Uxbridge, demonstrated the usefulness of this section. Mr. Allan showed fully a hundred very large finely-flowered examples of such fine varieties as Ensign, Julius, Mrs. Heal, Gloire de Lorraine, Mrs. L. de Rothschild, Turnford Hall.

Mr. W. H. Page, Tangley Nursery, Hampton, showed a beautiful mauve-pink decorative chrysanthemum named Thomas Page (A.M.), a splendid ruby-crimson single variety named Mrs. Walter Hemus (A.M.), and the fine zonal pelargoniums Winter Cheer, His Majesty, and Fiscal Reformer.

Messrs. H. Cannell and Sons, Swanley, presented a sloping bank of brilliant zonal pelargoniums, and a big collection of cut single chrysanthemums; among the latter Merstham Jewel, Cannell's King, Leo, Yellow King, Mensa, Sylvia Slade, and Mrs. J. Rowley were outstanding varieties. From the Manor House Nurseries, Cardiff, came a selection of single chrysanthemums that included most of the popular sorts.

The large contribution from Messrs. Wm. Cutbush and Son, Highgate, included a fine selection of handsome perpetual carnations, greenhouse heaths, winter-flowering begonias, skimmias, and polyantha roses in pots.

Seedling chrysanthemums, all single varieties, or nearly so, made up an interesting group from Messrs. Sutton and Sons, Reading; these were of great interest because of their decorative value and the fact that all had been raised from seeds sown in February of the present year.

Messrs. Whitelegg and Page, Chislehurst, and Mr. J. Clayton, Newham Road, Addlestone, each showed a good selection of single chrysanthemums. Messrs. J. Peed and Son, Norwood, were also large exhibitors of single and decorative chrysanthemums, and Mr. A. R. Russell, Richmond, displayed begonias and the showy new Gesnera Orange King.

Golden Spray, a rich yellow form of the well-known Source d'Or chrysanthemum, was displayed in large bunches by Mr. G. I. Tubbs, New Eltham, Kent.

The carnations exhibited by Mr. Burnett, Guernsey, were specially fine, particularly the vases of Britannia, White Enchantress, Mikado, May Day, Marmion, and the beautiful pink Mrs. H. Burnett.

Messrs. Allwood Brothers, Hayward's Heath, contributed a small group of carnations, wherein May Day, Fortuna, White Wonder, and Marmion were very good.

Messrs. Jas. Veitch and Sons' exhibit of winter-flowering begonias and bouvardias was a very pretty one, and the numerous varieties of the latter were interesting and instructive, as well as beautiful. Of the begonias the new orange-buff Fascination (A.M.), Rose Queen, deep rose-pink, and the older varieties Julius, Success, Mrs. Heal, and Ensign were extremely beautiful, the large plants being literally smothered with flowers.

Perpetual carnations were extensively displayed by Messrs. S. Low and Co., Enfield, who showed a rare lot of blooms of Lady Alington, Enchantress, White Enchantress, Rose Pink Enchantress, and other good varieties.

ORCHID COMMITTEE.

A very interesting group of cypripediums from Messrs. Cypher and Sons, Cheltenham, included such good things as C. insigne Harefield Hall, C. Milo, C. Germaine Opoix, C. Felicity, C. Sir Redvers Buller (very fine), C. insigne Sanderæ, C. Mdme. Jules Hye, etc.

Mr. W. R. Lee, Plumpton Hall, Heywood, sent a large-flowered, heavily blotched odontoglossum named O. Thais (F.C.C.), and also a beautiful hybrid named Trione (F.C.C.).

Mr. Alexander, orchid grower to Lieut.-Colonel Sir G. Holford, Westonbirt, brought up Cypripedium Chapmani Westonbirt var. (F.C.C.), Cattleya Harrisoniana alba Stanley's var., Lælio-cattleya Prince of Orange (F.C.C.), beautifully coloured gold and crimson, and Brasso-cattleya Digbyano-Mossiæ Holford's var. (F.C.C.), a magnificent form.

Mr. Hopkins, gardener to Francis Wellesley, Esq., Westfield, Woking, brought Lælio-cattleya Dengani (A.M.), a handsome hybrid between C. Dowiana and L.-c. Coppei, and Cattleya labiata Her Majesty the Queen.

Messrs. Mansell and Hatcher, Rawdon, contributed a specimen of Angræcum Wotschyi, with two long spikes of white, long-spurred flowers.

Messrs. Sander and Sons, St. Albans, put up a handsome bank of orchids, and here the leading features were Cattleya Fabia, a fine autumn bloomer, Lælio-cattleya Sapphirata, a C. maxima hybrid, L.-c. Stotteviana, the old and sweet-scented Maxillaria peta, Cypripedium Baron Schroder, C. triumphans Hye's var., C. Alabaster, and C. Thalia splendens.

The exhibit from Messrs. Charlesworth and Co., Hayward's Heath, was especially attractive by reason of its big batch of the brilliant Epidendrum vitellinum majus, Vanda cærulea, V. Sanderiana, and a few hybrid odontoglossums and odontiodas.

Messrs. W. B. Hartland and Sons, Ardcairn, Cork, presented quite a batch of the big Cypripedium insigne Harefield Hall, showing about a dozen and a-half flowers; with these were C. Thalia, Mrs. Wellesley, C. Maudiæ, C. insigne Sanderæ, etc.

Mr. Day, gardener to H. S. Goodson, Esq., West Hill, Putney, put up an interesting lot of orchids, and in the group the charming Cypripedium insigne Sanderæ was very largely represented, nearly a hundred blooms being presented. Other good things were C. Maudiæ, Lælio-cattleya Decia, L.-c. Felicia Goodson's var., Odontioda Devoniana, and Odontoglossum Wilckeanum, Goodson's var.

A large and beautiful exhibit of orchids came from Mr. G. Hunter, gardener to the Duke of Marlborough, Blenheim Palace, Woodstock. It consisted very largely of Vanda cœrulea and Cypripedium insigne Sanderæ, grouped in masses with ferns and green moss. One specimen of C. insigne Sanderæ carried about three dozen flowers.

Some fine odontoglossums from Messrs. J. and A. McBean, Cooksbridge, were associated with fine forms of Cattleya Fabia, Brasso-cattleya leucophæa (A.M.), Cypripedium Thalia var. Mrs. Wellesley, C. triumphans Bank House var., etc.

Cattleya Clarkiæ was prominently shown by Messrs. Hassall and Co., Southgate; Bulbophyllum sicybulbon was a notably interesting species on view.

Mr. E. V. Low, Vale Bridge, Haywards Heath, had Cypripedium Thalia gigantea, C. Germaine Opoix, C. Thalia Mrs. Wellesley, Cattleya Hardyana, and Odontoglossum grande aureum, etc.

From Sir Trevor Lawrence's collection at Burford Lodge, Dorking, came large plants of Maxillaria picta, M. phœnieantha, and Trichosma suavis, for which Cultural Commendations were awarded to Mr. W. H. White, the grower.

Calanthe Harrisi, pure white, was represented by about fifteen plants and thirty spikes, from Messrs. Jas. Veitch and Sons, Chelsea.

The orchids from Messrs. S. Low and Co., Enfield, again included a number of oncidiums, together with Dendrobium Phalænopsis Schroderianum, D. formosum giganteum, and numerous bright cattleyas and lælio-cattleyas.

A beautiful but light variety of Lælio-cattleya Henry Greenwood was exhibited by Mr. Musk, gardener to Captain Laycock, Wiseton, Bawtry.

FRUIT COMMITTEE.

Mr. W. Pope, Welford Park Gardens, Newbury, showed a collection of seedling apples, all varieties raised by Mr. Chas. Ross. Some very promising varieties were those named Excelsior, Redwing, Ella, Guelph, and Chas. Eyre, with such well-known sorts as Paroquet, Chas. Ross, Rival, and Encore.

Mr. E. Beckett brought up a goodly set of apples from Aldenham House, Elstree, and set up the fruits in good style. Varieties of special prominence among the seventy or more varieties were Mere de Menage, Peasgood's Nonsuch, Beauty of Kent, Tower of Glamis, Bismarck, Hambledon Deux Ans, King of the Pippins, Bramley's Seedling, Lane's Prince Albert, and The Queen. Most of the varieties were very highly coloured.

Mr. Tyser, Oakfield, Mortimer, showed some dishes of highly-coloured apples, and Mr. A. Allan, gardener to Lord Hillingdon, Uxbridge, contributed a few dishes of well-developed pears.

A most interesting exhibit of fruits and vegetables, bottled in glass-stoppered bottles, was made by Mrs. Banks, 102, Park Lane, W. There were 124 varieties of fruits on view, and every sample was beautifully bright and clear. The vegetables, too, were unusually well done, especially the butter beans, celery, asparagus, peas, and broad beans. It was a splendid exhibit of what an amateur may do.

CERTIFICATES AND AWARDS.

First-Class Certificate.—To Lælio-cattleya Prince of Orange; to Brasso-cattleya Digbyano-Mossiæ Holford's var.; and to Cypripedium Chapmani Westonbirt var., all from Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury; to Odontoglossum Thais, and O. Trione, from Mr. W. R. Lee, Plumpton Hall, Heywood.

Award of Merit.—To Lælio-cattleya Dengani, from Francis Wellesley, Esq. (gardener, Mr. W. Hopkins), Westfield, Woking; to Cypripedium Elatior Shrubbery var., from F. M. Ogilvie, Esq., The Shrubbery, Oxford; to Lælio-cattleya W. J Biggs, from Mr. W. J. Biggs, Browning Road, Enfield; to Cæsalpinia pulcherrima, from G. Evans, Esq., Baldock; to Begonia Fascination, from Messrs. Jas. Veitch and Sons, Chelsea; to Chrysanthemum Mrs. Walter Hemus and Thos. Page, from Mr. W. H. Page, Tangley Nurseries, Hampton; to Chrysanthemums Josephine and Marjorie Lloyd, from Messrs. W. Wells and Co., Merstham; to Chrysanthemum Primrose Girl, from Messrs. Jas. Veitch and Sons, Chelsea; to Chrysanthemum Norbury Yellow, from Mr. G. Kent, Norbury Park, Dorking; to Chrysanthemum Perfection, from Mr. W. J. Godfrey, Exmouth; and to Chrysanthemums Miss Margaret Gray and Miss Phyllis Bryant, from Mr. P. Ladds, Swanley.

MEDALS.

Gold.—To the Duke of Marlborough (gardener, Mr. Hunter), Blenheim, for orchids.

Silver-Gilt Knightian.—To Mr. E. Beckett, V.M.H., gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, for apples, etc.

Silver-Gilt Flora.—To Messrs. H. B. May and Sons, Edmonton, for davallias; to Messrs. H. J. Jones, Lewisham, for chrysanthemums; to Messrs. W. Wells and Co., Merstham, for chrysanthemums.

Silver-Gilt Banksian.—To Mr. A. Allan, gardener to Lord Hillingdon, Uxbridge, for winter-flowering begonias.

Silver Knightian. — To Mrs. Banks, 102, Park Lane, W., for bottled fruits and vegetables.

Silver Flora.—To Messrs. J. Peed and Son, West Norwood, for chrysanthemums; to Messrs. J. Veitch and Sons, Chelsea, for chrysanthemums, etc.; to Mr. Day, gardener to H. S. Goodson, Esq., Putney, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for cypripediums.

Silver Banksian.—To Mr. Jas. Box, Lindfield, for chrysanthemums; to Mr. H. Burnett, Guernsey, for carnations; to Messrs. S. Low and Co., Enfield, one for carnations and one for orchids; to Mr. P. Ladds, Swanley Junction, for chrysanthemums; to Mr. E. V. Low, Haywards Heath, for orchids; to Messrs. W. B. Hartland and Co., Cork, for orchids.

Bronze Flora.—To Mr. L. R. Russell, Richmond, for begonias and gesneras; to Messrs. H. Cannell and Sons, Swanley, for chrysanthemums and pelargoniums; and to Messrs. Hassall and Co., Southgate, for orchids.

West of England Chrysanthemum Society.

This society has now held exhibitions at Plymouth for a period of twenty years, and this season opened its annual show in the Guildhall on November 7. The display was a meritorious one, the exhibits being of high class, and the competition very keen. Mrs. Astor, the wife of the senior member of Parliament for Plymouth, opened the show.

The cut blooms, though not so numerous as in former years, were of high quality, and the specimen plants were excellently grown. The display of fruit was by far the largest ever staged in the hall, the quality was first-rate, and the colouring superb. Greenhouse plants were also well shown. One of the most attractive features of the exhibition was a beautiful table of salading, with which Mrs. Bainbridge won first prize. This exhibit was most artistically arranged; at the back two tall columns held a wealth of huge scarlet and yellow capsicums which made a brilliant show, while in the centre stood pyramids of mustard and cress. In all about forty varieties of salading were staged, these including chicory, asparagus chicory, variegated chicory, Batavian and moss-curled endive, chilis, large and small yellow currant tomatoes, English corn salad, Italian corn salad, radishes in many varieties, cucumbers, beetroots, dandelion, Japanese cabbage, cos lettuce, ceriac, Australian cress, American cress, celery, tarragon, watercress, and coriander.

A good group of miscellaneous stove and greenhouse plants won first prize for Messrs. J. Webber and Sons, the stand containing orchids of many kinds, Lilium longiflorum, carnations, crotons, palms, ericas, Begonia Gloire de Lorraine, cyclamen, and chrysanthemums. The first prize for a collection of twenty-four dishes of fruit, won by Mr. F. R. Rodd, was well deserved, excellent specimens of Canon Hall, Muscat of Alexandria, Appley Towers, and Gros Maroc grapes being staged, besides ten dishes of apples, seven dishes of pears, quinces, tomatoes, meddlars, and Melon Ringleader. A curiosity which attracted considerable attention consisted of ripe raspberries, shown by Messrs. Mears and Sons. Raspberries have in some districts been fruiting more or less continuously since the spring. Colonel the Hon. H. F. Trefusis, of Porthgwidden, Cornwall, received an Award of Merit for a collection of nine vases of violets in seven varieties, grown in the open.

The following is a list of first prize awards: Twenty-four Japanese blooms, the Rev. T. Sheepshanks. His stand contained fine specimens of Beecham Keeling, J. W. Molyneux (maroon-red), Madame G. Rivol (yellow), J. H. Silsbury, Frances Joliffe, Master David, F. S. Vallis, and Shanklin. Twelve Japanese blooms, the Rev. T. Sheepshanks; eighteen Japanese blooms in vases, the Rev. T. Sheepshanks; twelve vases of single varieties, Messrs. J. Webber and Sons; three vases of singles, whites, the Rev. T. Sheepshanks; three vases of singles, yellow, the Rev. T. Sheepshanks; three vases of singles, not white or yellow, Rev. T. Sheepshanks; miscellaneous group of stove and greenhouse plants, Messrs. J. Webber and Sons; four epecimen Japanese plants, Mr. E. Hannaford; one specimen, white, Mr. W. T. Ellis; one specimen, not white, Mr. C. Hannaford; six primulas, Mr. C. Bewes; six zonal pelargoniums, Sir John Jackson; six begonias, Gloire de Lorraine, Sir R. Pole-Carew; six table plants, Mrs. Bainbridge. In the local class for cut blooms the three chief prizes were won by Lady Buller. There were also classes for cottagers and artizans, but nothing of any special merit was shown. There were about thirty classes for fruit, in which the majority of first prizes were won by Mr. F. R. Rodd and Mr. H. St. Maur. Vegetables were very finely shown, Colonel Gore winning most of the first prizes.

The attractions of the show were much enhanced by the exhibits of nurserymen. Messrs. Robert Veitch and Son, Exeter, showed a pretty collection of new single chrysanthemums, amongst which were Mrs. T. Lawrence, Exonia, Jean Edwards, Florrie Stevens, Miss Lilian Bullivant, W. Jarman, Snowflake, Ceddie Mason, Manor House Beauty. A fine collection of winter-flowering carnations was also shown, and among other plants were Gerbera Jamesoni, Physalis Franchetti, Acacia Baileyana, Veronica Veitchi, Clerodendron trichotomum (in fruit), Cotoneaster augustifolia, Liquidambar styraciflua, and Crytomeria elegans. A silver medal was awarded this stand. The King's Acre Nurseries, Hereford, staged nearly two hundred varieties of apples, and were awarded a gold medal. The fruit, though not large, was well coloured. The Devon Rosery, Torquay, showed a splendid selection of fruit, the apples especially large, and received a silver medal. Messrs. Webber and Sons, Plymouth, showed a very large stand of perpetual-flowering carnations, for which they were awarded the society's Certificate of Merit.

Norfolk and Norwich Chrysanthemum Show.

This annual fixture, held under the auspices of the Norfolk and Norwich Horticultural Society—one of the oldest in the kingdom—was held at the St. Andrew's Hall, Norwich, on November 16, 17, and 18. This year the show could be summed up as a great success in all departments. The classes for Japanese blooms have not for many years had so many entries, nor such fine flowers. And the fruit classes were striking evidence of the past exceptional year for apples and pears. The secretarial duties are again in the able hands of Mr. C. E. Pilling.

The challenge cup for the best circular group was secured by E. Gurney Buxton, Esq. (gardener, Mr. T. Notley), who had not used any large, heavy blooms, but had used a graceful combination of singles, mostly with artistic effect. Sir Carl Meyer, Newport, Essex, was the winner of the first prize for forty-eight Japanese, and also for twelve incurved, and he had the distinction of winning both medals for best Japanese and for best incurved. Sir R. P. Beauchamp, Bart., Langley Park, scored top place in a strong class for thirty-six Japanese blooms. The first for twenty-four blooms was won by Mr. J. W. Brooke, Lowestoft. There were several smaller classes, the prizes being won by prominent local chrysanthemum growers. The best half-dozen of one white Japanese variety came from S. Newmann, Esq., who had Mrs. R. H. B. Marsham; and the best of any other colour was from Sir Saville Crossley, Bart. (gardener, Mr. F. Hanson), who staged six grand Mr. F. S. Vallis. The best six incurves were shown by Colonel Rous Worstead (gardener, Mr. W. Chettleburgh, who had Miss Cora Stoop.

Single and naturally grown decorative varieties are gaining great favour, and were the source of keen competition, G. E. White, Esq., Eaton, Norwich (gardener, Mr. W. Laws), taking first place in both classes. Baskets and hall vases appealed to the lady visitors for their artistic arrangement. Chrysanthemums in pots were not a great success. In the miscellaneous cut flower class, first honours went to Robt. Fellowes, Esq., Shotesham Park (gardener, Mr. Lewis Smith), for a dozen fine bunches of exotics, wherein orchids predominated. A class for a group of cut carnations upon a six foot run of tabling brought out three good entries. The Hon. C. Harbord, Gunton Park (gardener, Mr. W. Allan), was placed first; his blooms were very choice, and the arrangement good. Mr. W. Laws, gardener to G. E. White, Esq., had the newest varieties, and very bold flowers, but his arrangement was too heavy.

In the pot plant section, begonias of the Gloire de Lorraine type were the primary feature; extra good plants were staged by Edmund Reeve, Esq., The Grange, Catton (gardener, Mr. E. F. Greeve), who was placed first for pinks; and he very closely ran Dr. Osburne, who was first for white varieties. Miss Violet Fellowes, Shotesham Park, had it all her own way with orchids, and one was sorry that such was so, for these plants would have held their own, we think, in any local orchid competition. J. H. Gurney, Esq., Keswick Hall (gardener, Mr. F. J. Endersly), was winner for cyclamens with well-grown plants, carrying a profusion of flowers.

In the fruit section the judges had a tedious task, dozens of dishes of apples being entered in each class. Sir Saville Crossley, Bart., had the best nine dishes of dessert apples, and Colonel B. J. Petre, Westwick House (gardener, Mr. G. Davison), the best six. Mr. W. Allan's dish of Cox's Orange Pippin was placed first out of a dozen competitors. Pears were not so numerous, but of exceptional quality, the chief winner in all the classes being Colonel B. J. Petre, Mr. Geo. Davison, the gardener, being unbeatable in pear culture. Grapes were better than they have been for several years. The best three bunches of black came from Lord de Ramsey, Haverland (gardener, Mr. A. Coombe). The variety was Alicante, and of such a fine colour and shape of bunch, that they appealed to every visitor. The best single bunch was Gros Colmar, from the Marquis of Lothian, Blickling (gardener, Mr. H. G. Oclés); they were exceptionally well finished and coloured for this variety. White grapes brought out a strong fight between A. B. H. Goldschmidt, Esq., and Mr. W. Allan, the former winning for three bunches, and Mr. Allan for a single bunch. The best collection of fruit for a challenge bowl was won by Sir F. Adair, Bart., Flixton Hall (gardener, Mr. W. Hilson); his pears and grapes were beautiful, but he rather overdid the arrangement. The Earl of Stradbroke, Henham Hall (gardener, Mr. Simpson), had the best lot of kitchen apples, very fine fruits indeed, and he was also a notable winner in the potato classes.

All kinds of seasonable vegetables were shown in plenty, and when one considers the past dry season, and mostly light soils locally, it is a matter of much congratulation to the local growers.

The trade made a bold display. Messrs. Daniels Bros., Lim., Norwich, made a great feature of apples and pears, and also pot plants for decorative uses. Messrs. Hobbies, Lim., Dereham, made a feature of single chrysanthemums, staged in undulating banks of bold masses; nor did they forget that roses were still in bloom. Mr. G. W. Miller, Wisbech, had a nice lot of orchids. A new large culinary apple, named Norfolk Hero, was shown by Messrs. J. Rutter and Son, Outwell, Wisbech, who claim it to be a good keeping sort. There were a few other smaller exhibits from sundriesmen, etc., each helping to make a success of the show. We are pleased to be able to report that public interest was awakened, and that the "gate" showed an increase over last year.

National Vegetable Society.

There was a quite small attendance at the annual general meeting of this society, held at the Royal Horticultural Hall, Westminster, during the afternoon of Tuesday, November 21. Mr. Alex. Dean, V.M.H., presided.

The balance-sheet for the past year shows a turnover of £292 18s. 11d., and a balance in hand of £24 6s. 5d.

In the annual report, "the committee desire to express their great satisfaction with the annual exhibition, held in the Horticultural Hall, Westminster, on August 30 last. In spite of an unusually hot dry season, which was very detrimental to vegetables, the exhibits, though less in quantity than were those of the previous season, were of excellent quality, and showed how admirably the British grower can surmount adverse conditions.

"Whilst giving all praise to the numerous exhibitors, too hearty thanks cannot be given to all those noblemen, gentlemen, and seedsmen, who offered such valuable prizes, and thus attracted competitors from all parts of the kingdom.

"During the year extensive trials of early peas, carrots, Globe and long beets, and cauliflowers were conducted at the Times Experimental Station, Sutton Green, Surrey, under the care of Mr. H. Foster, son of the lamented Mr. Chas. Foster, the previous superintendent, whose loss to the society, and to horticulture generally, the committee cannot too sincerely deplore. Generally, and in spite of great heat and drought, the trials of peas, carrots, and beets were very satisfactory, whilst those of cauliflowers unfortunately failed, because of the great drought. For the privilege of holding the trials at Sutton Green, the committee tender to Lord Northcliffe very grateful thanks. A further and smaller trials of beets was conducted on Middlesex loam, at Marsh Farm, Twickenham, through the kindness of Mr. W. Poupart.

"The committee have great pleasure in reporting that within a few weeks of the holding of the National Exhibition, all prizes awarded were paid by cheque, and all accounts were settled, this leaving in hand a satisfactory balance.

"The committee desire to commend to the members the great and efficient services rendered to the society by the hon. secretary, Mr. E. G. Quick, whose labours have been of the highest value, and therefore strongly recommend that he be awarded an honorarium of ten guineas from the balance in hand. The committee would at the same time tender to their hon. treasurer, Mr. G. Wythes, V.M.H., their hearty thanks, not only for his very valued services as such, but also for his labours in securing from so many seedsmen seeds for trials, and sending them, under numbers only, to the respective trial grounds. So far as trials for the coming year are concerned, already extensive ones of lettuces and winter onions have been sown, both at Sutton Green, and at Twickenham the replies received from the numerous seedsmen sending such seeds showing not only great willingness, but also a degree of confidence in the honour, integrity, and practical capacity of the committee, which cannot be too highly appreciated, and merits warmest thanks. Not only are special thanks due to Mr. H. Foster, and to Mr. W. Poupart, but also to Mrs. Foster and Mrs. Poupart for their most welcome, abundant, and generous hospitality.

"The committee, having been urged to change the place of the exhibition from London to some more rural locality each year, have had before them a proposal to hold it during the autumn of the year 1912 at the very important and populous Herefordshire town of Watford. It is but a few miles from Euston, has a very capacious hall, which would afford ample room for a great exhibition, has a public-spirited population, and is not least a great gardening as well as an agricultural centre, hence it seems to present many advantages which merited full consideration. The committee have therefore decided to hold the next annual exhibition in the Clarendon Hall, Watford, on Wednesday, October 2, 1912.

"The need for largely increasing the membership of the society is great, and as vegetable culture is now so widespread, there should be every effort made by present members to bring in new ones. When mere flower societies can count members by thousands, the wide culture of such important food products as vegetables should bring equal members into the ranks of the National Vegetable Society."

The report and balance-sheet were adopted on the motion of the Chairman. The Duke of Portland was re-elected president; Mr. H. J. Wright becomes treasurer, in place of Mr. G. Wythes, who retired from the position; Mr. E. G. Quick continues as secretary, with Mr. A. Dean and Mr. Owen Thomas again chairman and vice-chairman respectively. To fill vacancies arising on the committee, Messrs. W. Gager, C. Burgess, Waterton, and G. Wythes were elected. Messrs. R. Pinches and W. R. Wilson were re-elected auditors.

On the motion of Mr. C. H. Curtis, seconded by Mr. Metcalf, a vote of thanks was accorded all the officers and committee of the society for their services during the year just ended, and this concluded the proceedings.

Cardiff.

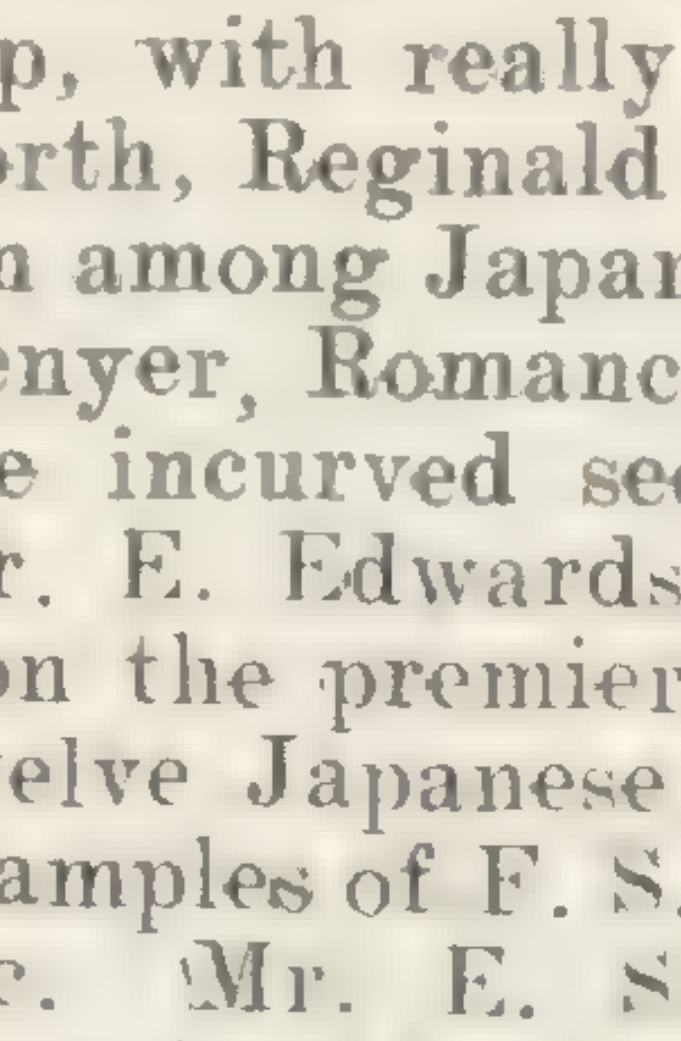
In the Park Hall—a capital site—the annual autumn show was held on November 8. The entries were not quite so numerous as usual in some of the cut bloom classes, but the quality left little to be desired; the absence of Mr. W. G. Drake, who has for so many years now exhibited so strongly and well at this and other shows, was very noticeable. Groups of chrysanthemums and floral designs were thoroughly well represented. Cottagers here show chrysanthemums remarkably well, and this year was no exception. The secretary, Mr. Mountney, worked hard, as usual, to make the show one of the finest in the West.

CUT BLOOMS.

The leading cut flower class was for eight varieties, Japanese, three blooms of each, arranged in vases, and a challenge cup with a cash prize was the chief inducement. Three competed, the best set coming from Mr. J. Duff, gardener to F. S. Williams, Esq., Bryn Glas, Newport, who was an easy first with excellent blooms of Mrs. A. T. Miller, Hon. Mrs. Lopes, Master David, President Viger, Mrs. W. Knox, Reginald Vallis, and Bessie Godfrey. Mr. H. F. Farmer, gardener to the Marquis of Bute, Cardiff Castle, second, with fresh blooms a trifle smaller. Messrs. Joy, Courtrallis Gardens, third. For twelve Japanese distinct, four competed, the best set, an even lot of good blooms coming from Mr. J. E. Davies, gardener to W. Godfrey Clark, Esq., Lalygaru; Mr. Farmer followed closely.

Incurved varieties were well staged, and Mr. J. Evans, gardener to Sir C. E. J. Phillips, Picton Castle, Haverfordwest, won for twenty-four, with large specimens, a trifle rough; Embleme Poitevine, Mrs. J. Wynne, Duchess of Fife, Fanny Lemon, Romance, G. Eclipse, and G. W. Matthews were the most noteworthy varieties. For twelve Japanese and the same number of incurved, Mr. J. Evans secured the challenge cup, with really fine blooms of Lady Letchworth, Reginald Vallis, and W. A. Etherington among Japanese, with Edwin Thorp, Mrs. Denyer, Romance, and Embleme Poitevine in the incurved section; Mr. Farmer, second. Mr. E. Edwards, 141, Severn Road, Cardiff, won the premier place in a strong entry for twelve Japanese, as an amateur, with fresh examples of F. S. Vallis and Hon. Mrs. Lopes, etc. Mr. E. Skarey, 40, Redlands Road, second. Mr. Farmer won the Courtis challenge cup for twenty-four Japanese in not less than eighteen varieties, with a desirable set, including Countess of Granard, F. S. Vallis, Rose Pockett, Bessie Godfrey, Mrs. E. Pearson, and Master David as the leading specimens. Mr. T. E. Stephens, gardener to A. F. Hill, Esq., The Garth, Lisrave, second, with smaller flowers; four competed.

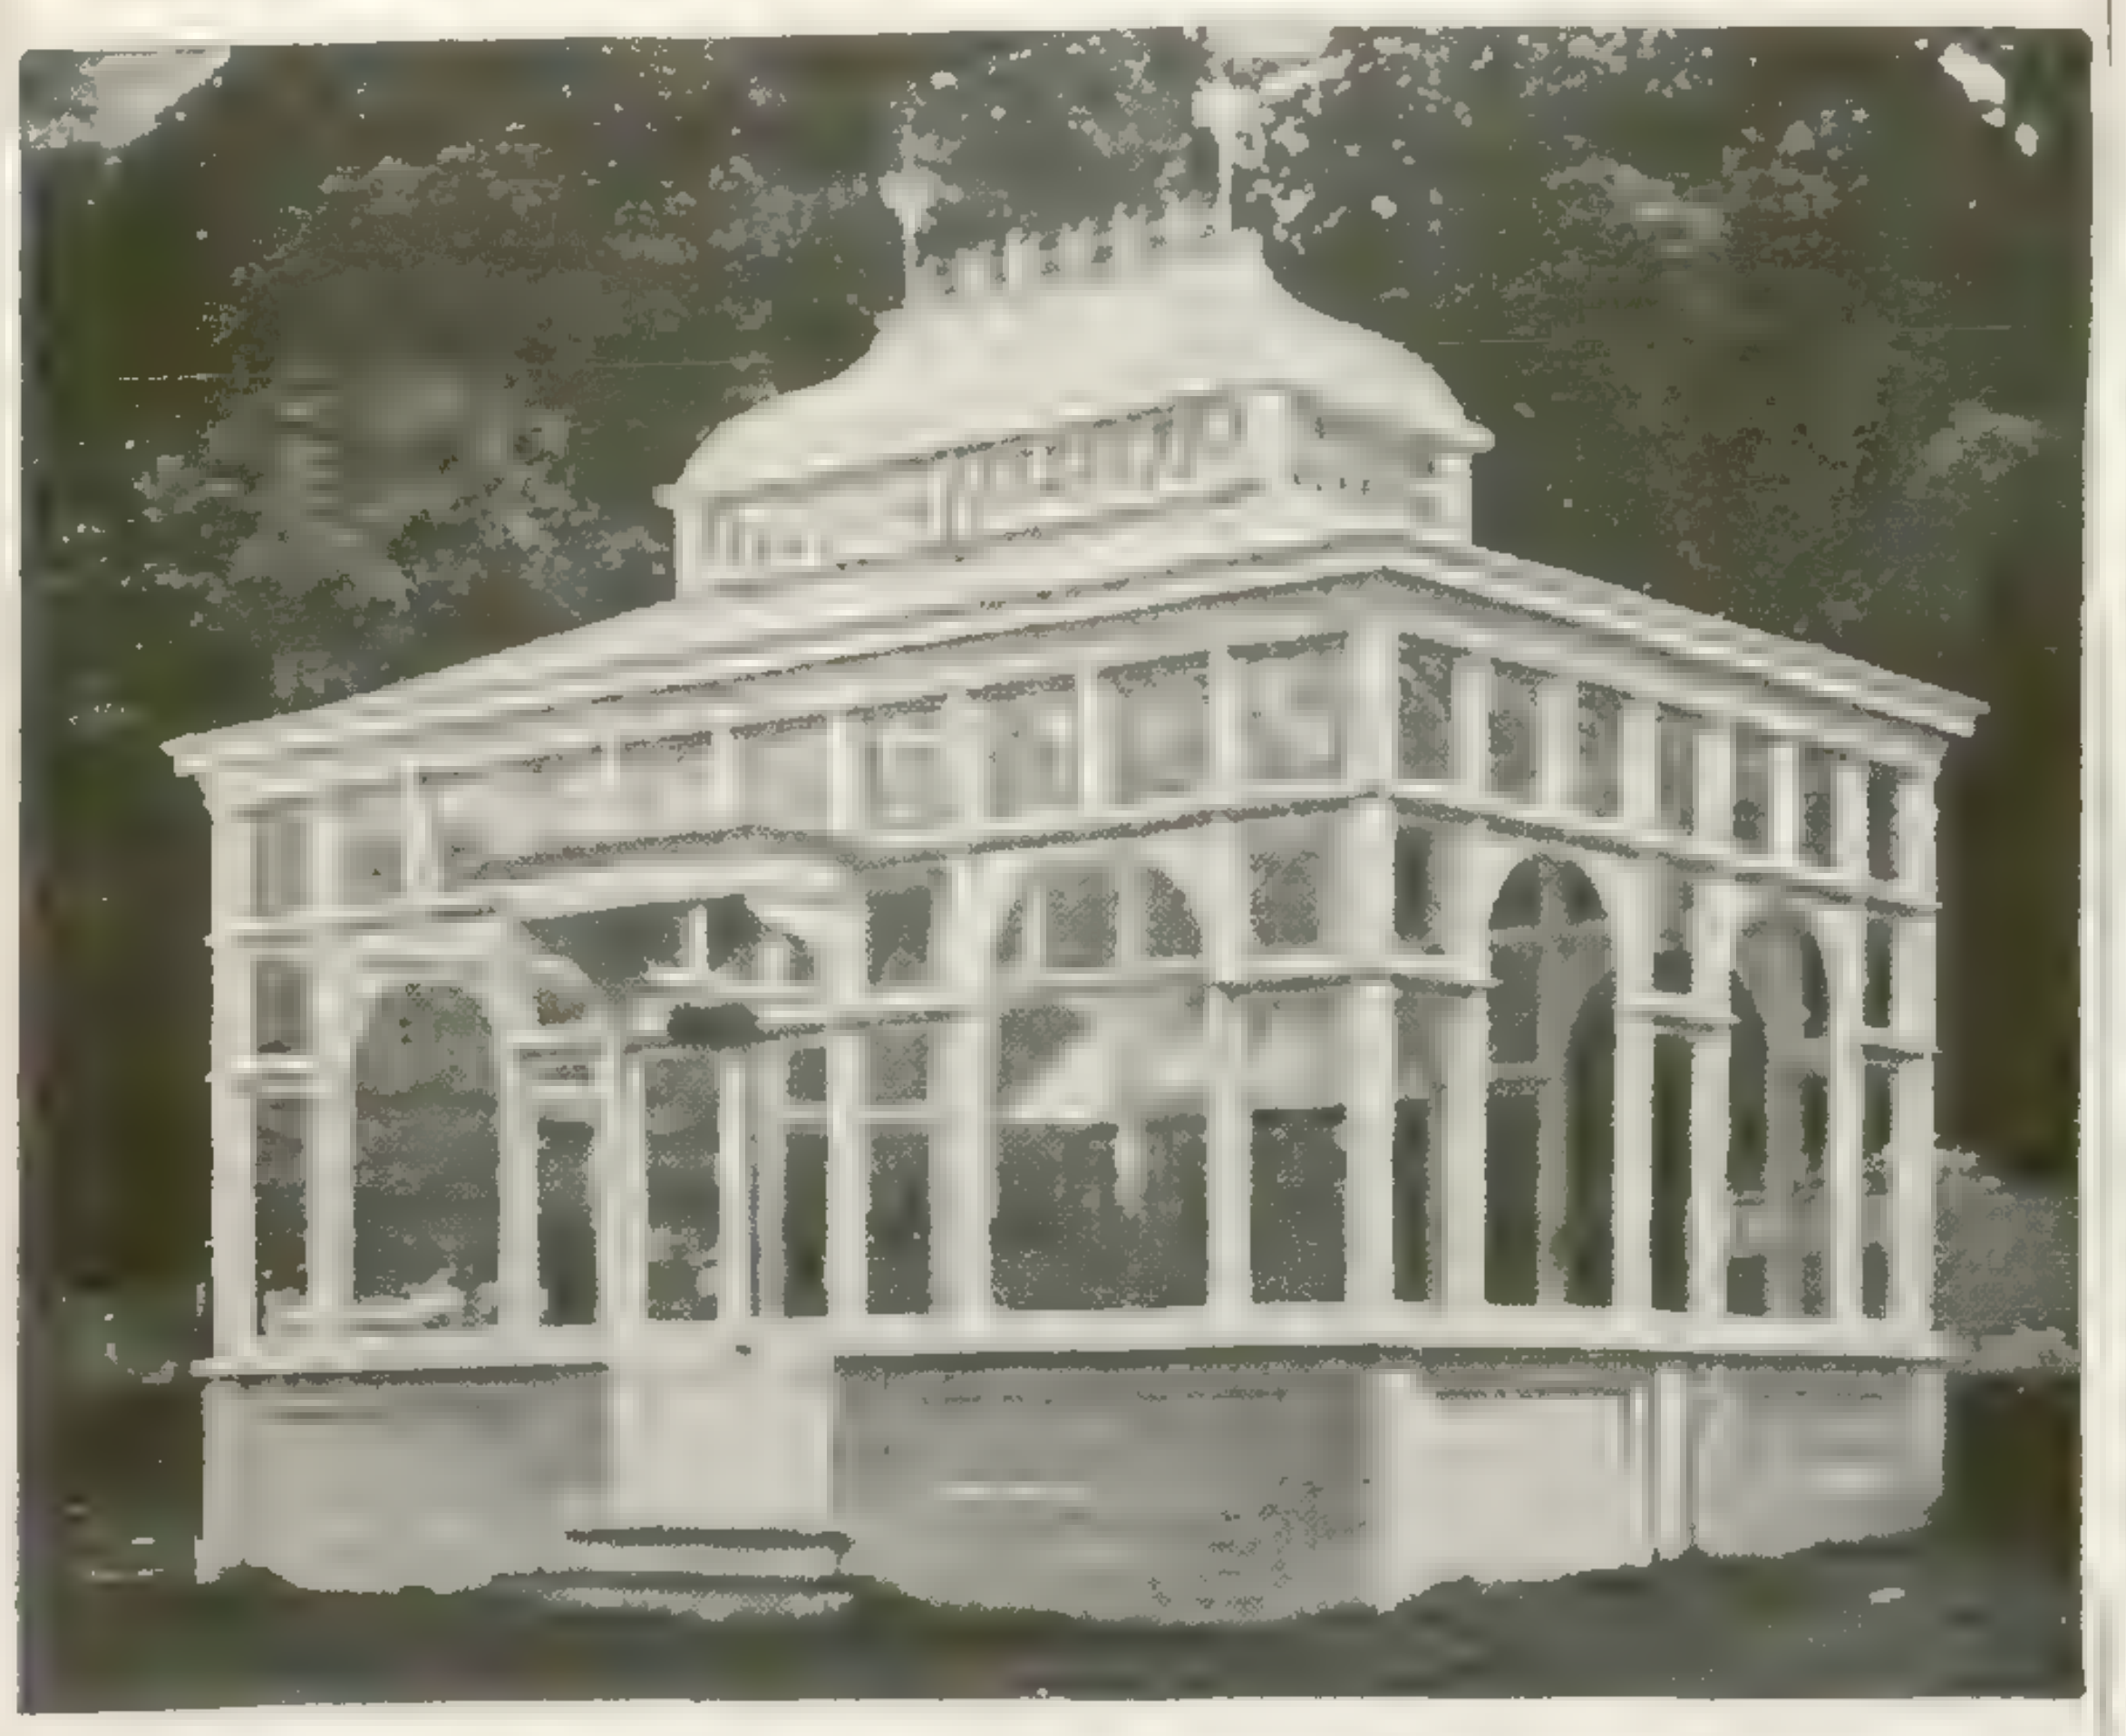
Single-flowered varieties have long received much encouragement here, and on this occasion they were well represented. For six vases, three sprays in each, Mr. T. Bindon, gardener to S. Wallace, Esq., Newport Road, Cardiff, was easily first with grandly developed blooms of Metta, Mrs. E. Roberts, Altrincham Yellow, Manor Beauty, Eureka, and George Williams; Mr. G. H. Screen, 10,

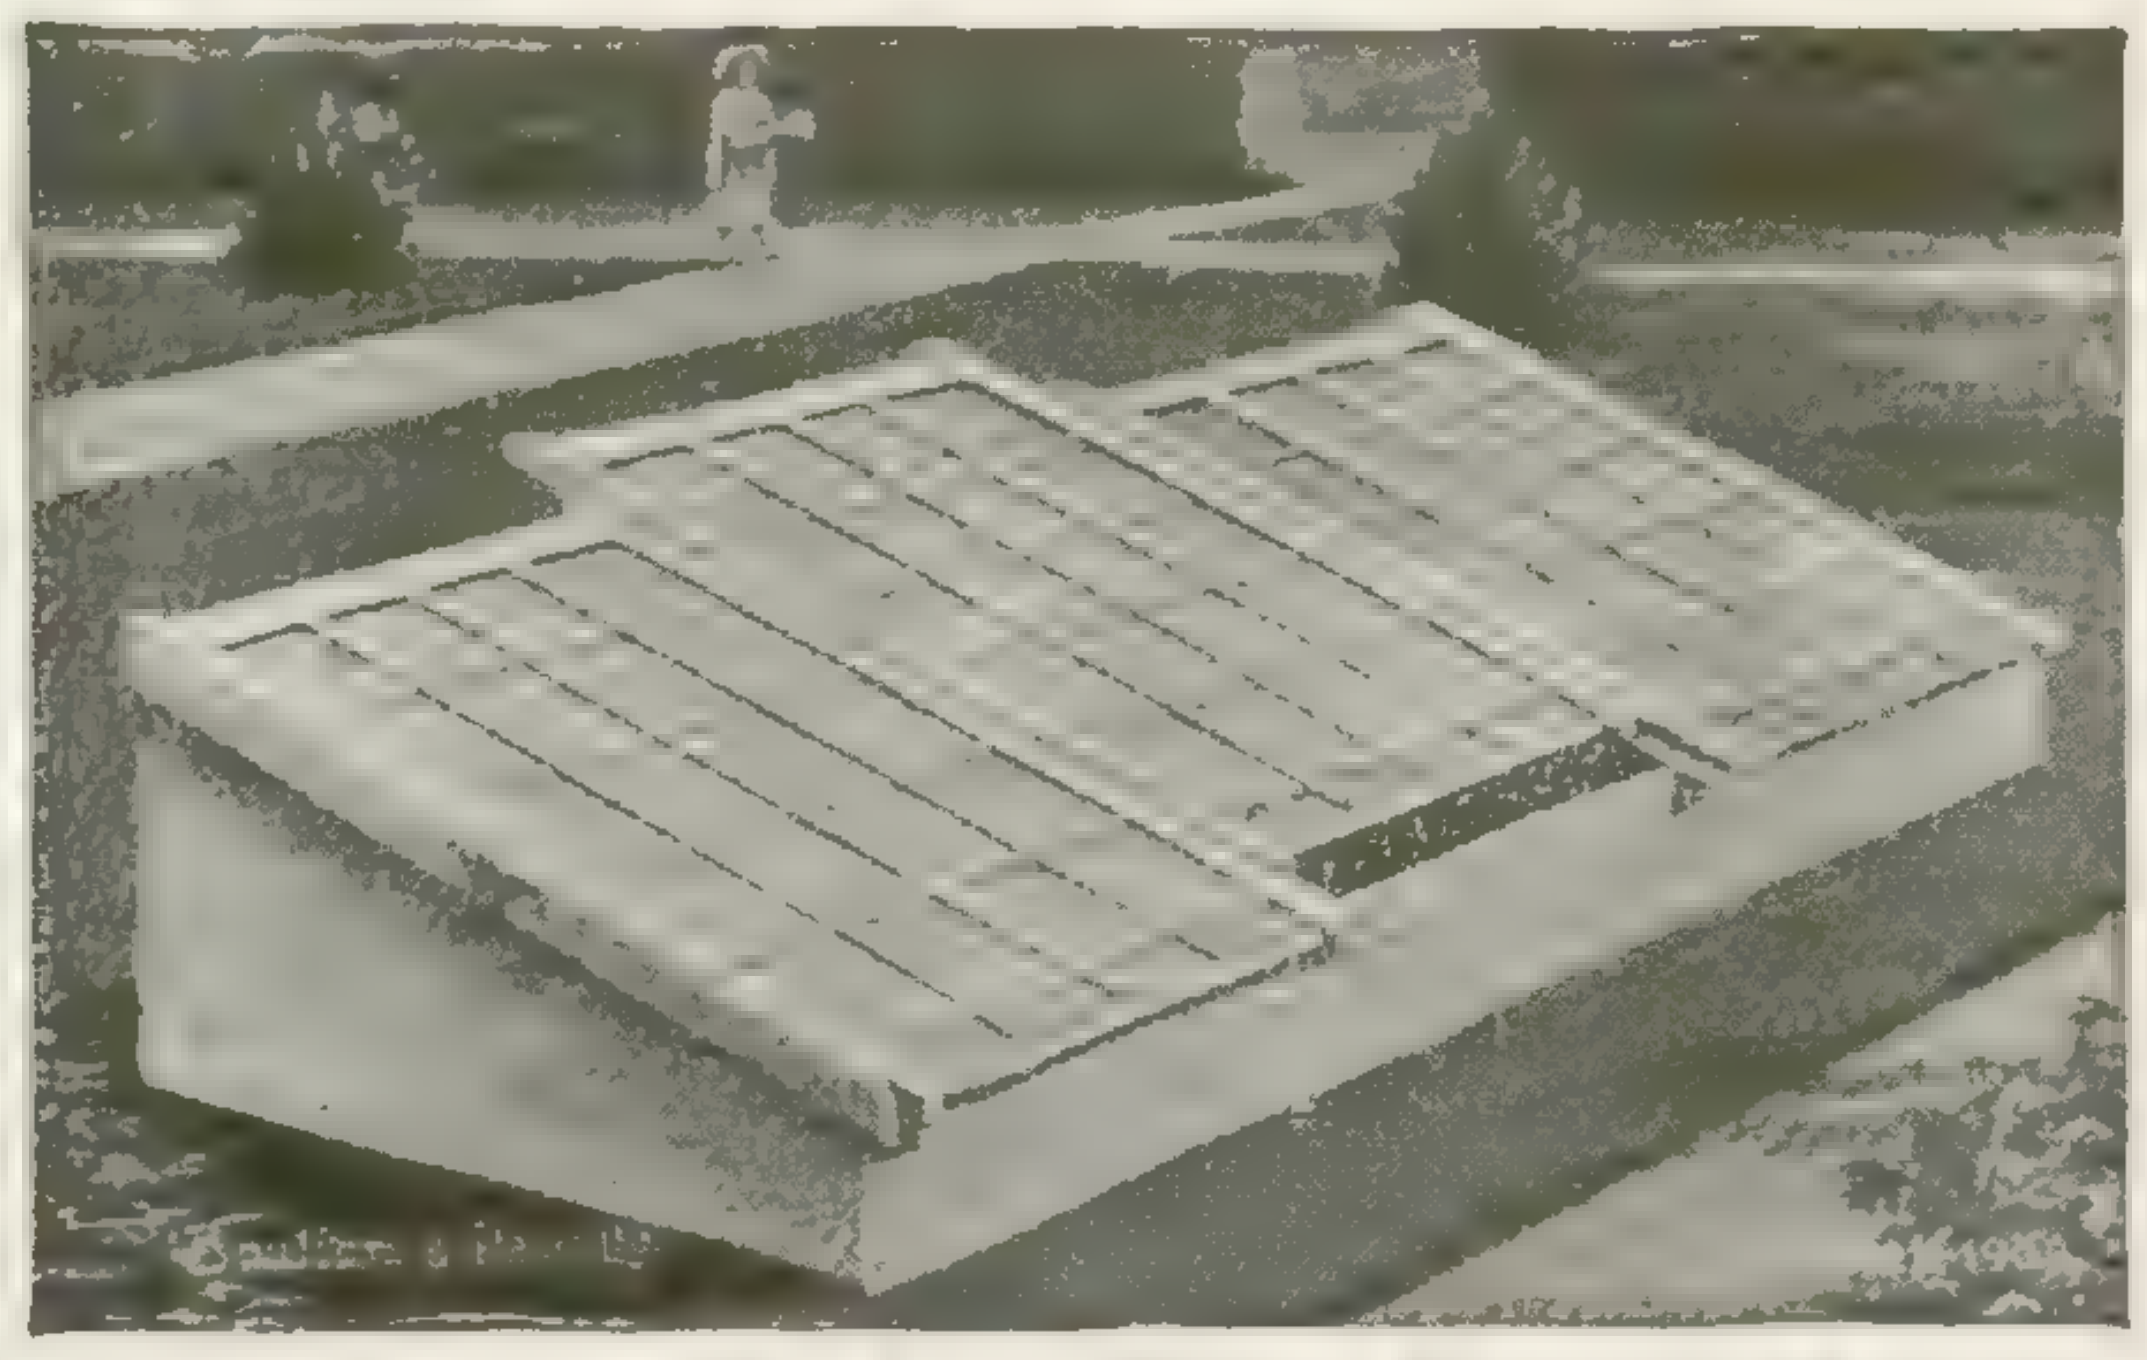


The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price 10/6. Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).





BOULTON & PAUL, LTD., HORTICULTURAL BUILDERS, Norwich.

ATTRACTIVE, PRACTICAL GLASSHOUSES.

Ladies and Gentlemen waited upon by appointment.

CARRIAGE PAID on orders of 40/- value to most Goods Stations in England.

HEATING APPARATUS installed in COUNTRY HOUSES, HORTICULTURAL & PUBLIC BUILDINGS.

No. 75.—MELON and CUCUMBER FRAME.

4ft. by 6ft. ... £2 0 0 | 8ft. by 6ft. ... 3 0 0
Painted three coats. Glazed with 21oz. glass.

No. 77.—VIOLET FRAME, 6ft. by 4ft. Similar to No. 75, with Two Lights... 35/-

SEND FOR ILLUSTRATED CATALOGUES.

Every part of these Houses is thoroughly well made, painted three coats, CLAZED AT OUR WORKS WITH 21oz. GLASS and CARRIAGE PAID.

No. 49A.—Span, 10ft. by 8ft. £11 10 0
No. 47A.—Lean-to, 10ft. by 7ft. £9 10 0

All parts are numbered ready for easy re-erection by any handy man.

Plassay Street, Penarth, was a good second. Nine took part in a class for the best-arranged vase of singles, and Mrs. G. H. Screen won with an effective display of well-grown flowers, Mr. Bindon following with better blossoms, but in too many colours.

Groups of chrysanthemums were numerous, and in the open class Mr. W. Treseder, Cardiff, led with very finely flowered Japanese and single varieties, making a bold and effective display with these and crotons, ferns, etc. The "Thomas Andrews" challenge cup, with a cash prize, offered for a group of chrysanthemums only, which was secured by Mr. A. Brown, gardener to the executors of the late J. Howell, Esq., Grove House, Cardiff, with dwarf plants, carrying handsome blooms effectively staged; Mr. Hatherdale, 53, Shakespeare Street, Cardiff, second. The best-arranged group of miscellaneous plants, in 40 sq. ft., was contributed by Mr. Mackintyre, gardener to Lady Hill, Rookwood, Llandaff. Mr. Treseder won the premier place for the best hand and bridal bouquet with charming exhibits.

Trade exhibits added much to the interest of the show. Messrs. Stuart Low and Co., Bush Hill Park Nurseries, Enfield, had orchids in quantity and carnations (gold medal). Messrs. Mansell and Hatcher, Rawdon, Leeds, staged orchids of an interesting character (gold medal). Messrs. Basham and Sons, The Nurseries, Bassaleg, Monmouth, had a fine display of apples of the leading varieties in splendid condition (gold medal). Messrs. G. Williams and Son, Manor Road Nurseries, Cardiff, had chrysanthemums in quantity (silver medal).

Southampton.

NOVEMBER 7 and 8.

The annual autumn show was held in the Victoria Hall, and was quite a good display. Especially fine were the incurved blooms for so early in the season, and the decorative sections, which are here made a feature of, were remarkably fine. Groups and plants were commendable. Baskets of autumn foliage were quite gorgeous in their colouring. Fruit and vegetables were highly meritorious. The management was, as usual, of the best under the careful guidance of Mr. C. S. Furdge, who has held the post of secretary here for the last forty years.

PLANTS.

For a group of decorative chrysanthemums, arranged with palms, ferns, etc., there were but two entries. Mr. F. G. Bealing, Bassett Nurseries, Southampton, won the premier award with an imposing array of well-grown plants of incurved, Japanese, and single varieties, arranged in a series of mounds, each surmounted by a specimen palm, the whole being edged with ferns. Mr. T. Hall, gardener to Ellen, Lady Swaythling, South Stoneham House, Southampton, was second.

Single-flowered varieties were well shown by Mr. Bealing in the class for six plants; Mr. C. Hosey, gardener to J. C. D'Esterre, Esq., Glenfield Hill, Southampton, second. Mr. Hosey led for four bush plants, staging specimens fully 4ft. in diameter, freely-flowered, and not too stiffly trained.

CUT BLOOMS.

The leading vase class was for eight Japanese varieties, distinct, three blooms of each. Of the four competing, Mr. W. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, was the most successful, winning with an even set of fine flowers well staged. The following were conspicuously good: Duchess of Sutherland, Master James, Vera Dow, Mrs. W. Knox, Mrs. A. T. Miller, Mrs. R. H. B. Marsham, and F. S. Vallis. The second place was occupied by Mr. W. Baxter, gardener to Captain Dalgety, Lockerley Hall, Romsey, with very fine blooms, but a trifle irregular. White-flowered Japanese, in two varieties, three of each, made an interesting class. Mr. W. Hall, gardener to Major Chichester, Embley Park, Romsey, was first with W. F. Lever and Mrs. A. T. Miller. The latter was judged to be the premier Japanese bloom in the show. Mr. C. Hosey, gardener to J. C. D'Esterre, Esq., Elmfield Hill, Southampton, with Miss A. Niccoll and Purity in good order, was second. For the same number of blooms, any other than white, six entered, and Mr. W. Hall, with typical examples of Rose Pockett and Bessie Godfrey, led. Mr. Baxter depended upon F. S. Vallis and J. H. Silsbury. Mr. Baxter led for four varieties of Japanese blooms suitable for decoration, six of each, with Mdme. P. Radaelli, Master James, Frank Payne, and Lady Talbot; Mr. C. Hosey coming next with a good exhibit.

A class for decorative varieties, excluding Japanese and singles, brought six entrants. Mr. F. Bealing led with a remarkable exhibit of high-class blooms of Romance, Embleme, Poitevine, and the anemones Delaware and Mdme. Herewege; Mr. A. J. Marsh, gardener to M. Hodgson, Esq., Kingsworthy, Winchester, second. Single-flowered varieties, disbudded, in six vases, distinct, an unlimited number of blooms allowed, produced a highly interesting display. Mr. A. J. Marsh, with grandly-developed blossoms of Mrs. R. C. Pulling, Keston Gem, Altrincham Yellow, Mensa, Sylvia Slade, and Mrs. E. Roberts led, and Mr. Bealing was second with a handsome set. Five contributed undisbudded singles in six varieties, Mr. Marsh again winning with freely-flowered sorts; Mr. C. Dymett, Freemantle Nurseries, second.

For twenty-four Japanese blooms arranged on boards, in not less than sixteen varieties, there were five entrants, these making a good display, Mr. Baxter winning easily with a full, solid, fresh example, mainly of the semi-drooping section: Mrs. G. Hemming, Eclipse, Lady Talbot, Master James, Frances Joliffe, W. Mease, D. B. Crane, and The Hon. Mrs. Lopes were notably good; Mr. Marsh second. Mr. W. Hall won for twelve Japanese, distinct, followed by Mr. F. Chandler, 75, Shirley Road, Southampton.

Incurved varieties were remarkably well shown. For eighteen blooms, in not less than twelve varieties, three competed. Mr. Marsh, with an extremely fine display, won with ease. The blooms were large both in diameter and depth, fresh, well-finished, and capitally staged. Especially fine were Embleme Poitevine, Mrs. Denyer, Romance, H. W. Thorp, W. J. Higgs, Clara Wells, and Godfrey's Eclipse. Mr. Mease followed with a less even set, yet containing many high-class flowers.

Amateurs staged numerously and well. Mr. E. J. Tofield, Chandler's Ford, won for twelve Japanese with a praiseworthy exhibit; Mr. A. S. Hill, London Road, Southampton, second.

FRUIT AND VEGETABLES.

Fruit was excellent. For two bunches of black grapes, Mr. G. Ellwood, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, Hants, won with Alnwick Seedling; Mr. W. Hall second with Appley Towers. Alicante was well shown in the class for two bunches of that variety by Mr. W. Hall. The latter also had the finest white grapes, showing exceedingly fine Muscat of Alexandria. He was also first in the class for one white bunch, and for one of any black variety with Mrs. Price in fair condition. Apples were a strong feature. Twelve staged four dishes of dessert sorts, and Mr. W. West, gardener to Mrs. M. Knox, Holt Hatch, Alton, won with remarkable examples of Cox's Orange, Blenheim, Allington, and Ribston Pippins. For a similar number of kitchen varieties, Mr. W. Sims, Stonehead, Seals, Wilts, won with Peasgood's Nonsuch and Bramley's Seedling especially fine. Fourteen staged a single dish of dessert apples, other than Cox's Orange Pippin, and Mr. Ellwood won with Blenheim Orange of exceptional colour.

Vegetables were a remarkable display, as they always are here. Messrs. Toogood and Sons offered six prizes for six dishes, producing eight entries. Mr. Ellwood was invincible here, as also in the class provided by Messrs. Sutton and Sons for six dishes.

Trade displays were numerous, adding much to the interest of the show. Messrs. Toogood and Sons, Southampton, arranged a remarkable collection of vegetables, for which they were awarded a gold medal. Messrs. B. Ladhams and Co., Shirley, Southampton, had an effective rock garden, for which they received a silver medal. Messrs. E. Hillier and Sons, Winchester, with a collection of superb apples, also received a silver medal, Messrs. W. H. Rogers and Son, Southampton, receiving a similar award for apples. For three dozen dishes of highly-coloured apples, effectively arranged, Mr. Myers received a silver-gilt medal.

Reading Gardeners' Association.

With the object of assisting the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund, the members of the Reading and District Gardeners' Mutual Improvement Association held a charming exhibition of flowers and fruit in the Reading Corn Exchange, on Wednesday, November 8. Similar exhibitions have been held for several years past, and a sum of about £20, after the payment of all expenses, has usually been realised.

Chrysanthemums predominated, but there were groups of zonal pelargoniums, Gloire de Lorraine begonias, roses, primula, crotons, dracænas, etc. Opposite the entrance Sir Rufus Isaacs, M.P., showed a group of zonal pelargoniums and bright scarlet salvias, backed with white chrysanthemums. The growing of chrysanthemums from seed is an interesting pursuit, and in this department Messrs. Sutton and Sons were conspicuous with a large group of single seedlings. It was a delightful collection, presenting great decorative possibilities, and a wide range of colouring. Flanking the platform were similar groups belonging to Mr. Leonard Sutton and Mr. M. H. Foquet Sutton. Close to Messrs. Sutton and Sons' seedlings, Mrs. Bland Garland had a group of fine chrysanthemums mingled with salvias, pelargoniums, and coleus. Winter-flowering begonias were a beautiful display of pink and white blossom. A large group came from Mr. C. Griffith, and the excellent specimens which adorned the whole length of the fruit stage were the property of Mr. S. B. Joel. Great admiration was expressed for three groups of zonal pelargoniums from Mr. S. Wheeler, Captain D. M. Miller (Blandford Lodge), and Mr. C. T. Evans. Captain Miller's specimens were all singles, but without exception the clusters were large, and the florets of good shape and substance. Mr. W. Howard Palmer (gardener, Mr. W. C. Moles) sent a fine group of foliage plants.

Mr. J. Hicks, of Twyford, exhibited roses, and Mr. Stanton showed many vases and baskets of dried flowers and grasses, having remarkably decorative properties.

The fruit shown deserves high praise. It was carefully staged, and, besides being a constant source of interest to visitors, constituted an educational exhibit of great value. Sir Charles Henry, M.P., and Mrs. Noble, of Park Place, sent particularly large collections of apples; but for their rich colouring the specimens forwarded by Mr. A. C. Fraser, Mongewell Park, Wallingford, were very remarkable. Fine specimens, both in colour and shape, were sent by Alderman F. B. Parfitt, the president of the association, and Mr. G. Drew took the opportunity, in preparing the University College exhibit, of showing how to market choice fruit and flowers. Mrs. Noble's exhibit, it may be added, included excellently bottled fruits, home-grown citrons, fruits of the medlar quince, Japanese dates (Diospyros Kaki), almost resembling a peach in colour and a tomato in shape. A curiosity was a box of Up-to-date potatoes indicating how new tubers may be secured at almost any time of the year.

In addition to those named above, should be mentioned Mr. F. W. Nicholson (Shiplake), Mrs. Collins (Stoneham House), Mr. T. R. Harman (Sindlesham House), Miss Cripps (Preston), Mr. H. Collins (Leopold House), Mr. T. Allsop, Mrs. Bird (Shrublands), Mr. E. C. Powell (Caversham), Mrs. Austen (Whitley Lodge), Mrs. C. Smith (Ravenswood), Mr. L. R. Erskine (Binfield Manor), Mr. H. R. Beeton (Hammond's End), Mr. H. Dunlop, Mr. E. Parker, Mr. G. Bryant, Mr. A. Webb, etc.

FORTHCOMING ENGAGEMENTS.

WEDNESDAY, November 29.—Irish Gardeners' Association.

National Chrysanthemum Society's Annual Dinner at the Holborn Restaurant.

THURSDAY, November 30.—Royal Horticultural Society's Colonial Fruit Show; three days.

Manchester and North of England Orchid Society.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

RED GRUBS IN CHRYSANTHEMUM STEMS.—W. B.: We cannot find any reference to the grub of a small fly feeding in the stems of chrysanthemums, but two flies are said to feed in chrysanthemum blooms, i.e., Cecidomyia cyngenesiæ and C. chrysanthemi. Possibly the tiny grubs may be one of these. We shall be glad, should you make any further discoveries in this direction, if you will kindly communicate with us.

APPLE AND PEAR TREES.—S. H. G., South Devon: Farmyard manure and lime should not be used at one and the same time, as lime acts chemically upon the manure, and quickly sets free the nitrogen, in the form of ammonia. If the trees seem to need assistance, give a moderate dressing of decayed farmyard manure, lightly forking this in. Pruning may be done at once, and the clearing up and manuring may follow. If the pears have made strong growth, do not manure them unless such growth is well set with fruit spurs and buds. Root-pruning should not be performed unless you are quite satisfied that the growth made is excessive and unfruitful, and then it should only be done in the case of one half of the roots this year, leaving the other half for the following winter. Instead of taking out a trench all round the tree, only do so round one-half; such a trench should be about 3ft. or 4ft. from the trunk, according to the extent of the roots, and the grossness of the growth.

CYMBIDIUM INSIGNE.—We commend to the attention of our readers who are expert in orchid culture the following letter from a Wellingborough correspondent (D. B. W.).: I am very interested in orchids, and read with great delight and profit the weekly notes on these plants under the heading of "Work for the Week," and literally devour any special articles on orchids or orchid culture. But I have a plant of Cymbidium insigne Sanderæ, which I am not successful with, and I should very much like some assistance in this matter from your able correspondents. Two plants were potted up at the same time, and they have been together in an intermediate house; one has grown well, and is now throwing up a flowering spike already 2ft. high, and the foliage is clean and healthy. The other plant has never made such strong growth, and on nearly every leaf and growth there are black spots. I wish to express my thanks for your kindly assistance on previous occasions, and to ask how I can cure the cymbidium of black spot, and bring it into a healthy condition like that of its neighbour.

SWEET PEA SHOW OF 1912.—J. E. S., Brentwood: As already announced in these columns, the exhibition of the National Sweet Pea Society will be held at the Royal Horticultural Hall, Westminster, on Tuesday and Wednesday, July 9 and 10, 1912.

SPORTIVE CHRYSANTHEMUM.—D. R., Cromarty: It is not an uncommon thing at all for a chrysanthemum to produce stem sports of the character of those sent. There is always a difficulty in propogating from a branch sport of this kind, but if the stem is placed in a warm moist place it may possibly produce growth.

NAMES OF PLANTS.

W. J., Baldock.—1, Gesnera exoniensis; 2, Selaginella cæsia.

S. E. C., Everton.—1, Skimmia japonica; 2, Begonia Rex; 3, Tillandsia Lindeni.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Interpretations of Experimental Results.

MR. GEORGE BARKER.

So many factors have to be taken into consideration in conducting experiments in field and garden, and interpretating the results obtained, that it is extremely difficult to avoid errors of more or less importance. This fact has been fully recognised for some time past by those who have had experience in scientific investigations, and it has been felt that as experimental results are more or less misleading to practical men unless correctly interpreted, an effort should be made to secure the highest possible degree of accuracy. With this object in view, several papers were contributed to the meeting of the British Association for the Advancement of Science, held at Sheffield last year, in which the several aspects of experimental error were fully dealt with. As the papers were contributed by authorities of the highest eminence in their respective branches of scientific enquiry, and in view of the importance of the subject, the British Association suggested that the Board of Agriculture should undertake their publication for the purpose of obtaining for them a much wider circulation than they would have if issued merely as part of the British Association's report. The suggestion has been acted upon, and the papers have been issued as a supplement to the current issue of the "Journal" of the Board, and may be obtained at a small cost. There are four papers, all of much value, but those of more immediate interest to horticulturists are: Mr. Spencer Pickering's paper on experimental error in horticultural work, and the paper in which Mr. A. D. Hall and Dr. E. J. Russell deal with the interpretation of the results of field trials. In the second of these two papers it is pointed out that the value of an experiment depends upon the degree of confidence that can be attached to the result, i.e., on the probability that a similar result will be obtained when the trial is repeated; and also that all which can be reasonably demanded from a set of field experiments is a workaday measure of certainty, or, in other words, a probability of attaining a specified result that to spend money on the expectation becomes a reasonable speculation. An experiment is defined as a question put to Nature, but in field experiments one of the chief difficulties lies in putting the question in such manner that the answer will really bear upon the point it is desired to test. It has to be recognised that the materials with which the experiments are being made—crops, for example—are living organisms, and, as such, are very complex, the outcome of a number of factors. The chief function of a manure is to supply nutrient matter to the plants, and manurial trials are usually carried out on the assumption that a comparison is being made between the effects of certain plant foods only. But, as the authors of the paper so clearly state, some manures exert physical actions upon certain soils, which, by affecting their water content, may obscure the effects of the manure as plant food. It is therefore advised that in arranging a set of field experiments to keep the question very clearly in view, and to be careful to avoid as far as possible all secondary factors, which may exert a disturbing influence. Experimentalists are warned that, however careful their design, they must not expect a "correct" answer, as it is at once seen from the divergence in the answer returned when the question is repeated in different places or at different times. The problem is to construct the most probable result from the different answers, and to that end certain principles must, it is suggested, be observed. The principles to be kept in view are, the authors state: (1) At the outset the issue to be tested must be defined, and the experiment kept simple by confining it to a single, or at most, to a very few issues; (2) the result must be examined to ascertain how far they belong to a single series comparable inter se, or how far they have been irregularly affected by some unanticipated factor; (3) in any series admitting comparisons, the magnitude of the experimental error must be determined. Special attention is directed to the fact that lack of uniformity in the soil leads materially to corresponding variation in the crop results, and that over a field that is apparently uniform, there are to be found differences due to natural causes or to past treatment. It may be differences in the water content, which can only be determined with a proper degree of accuracy by the weighing machine, or a difference in the plant food in the soil due to previous dressings. Mr. Spencer Pickering's paper is confined to experimental work in connection with the various kinds of hardy fruits, and it need hardly be said that the author writes with an experience that is quite unique. At the outset, Mr. Spencer Pickering states that experiments in horticulture wherein the behaviour or trees or bushes under varying condition are being studied exhibit errors from sources which do not generally affect experiments in agriculture. These, he states, are due (1) to the relatively small number of plants which it is possible to include in each experiment; (2) to the necessity for branch treatment; (3) to the large number of varieties of each kind; and (4) to the fact that the life of the tree, or even of small fruit-bearing plants is of much greater duration than that of farm crops. It is suggested that in the case of apples and pears, the trees should be planted at least twenty feet apart, which allows a hundred trees to the acre. To have relatively large plots of each variety when a considerable number of varieties have to be tested is therefore out of the question, and such plots Mr. Spencer Pickering does not consider necessary, or even desirable, because of the lack of uniformity in the land of England. The most satisfactory results are, he considers, obtained by planting small plots in situations where the conditions appear to be uniform, and duplicating experiments in other situations where similar uniformity exists. The importance of uniformity in the land on which experiments are conducted cannot be overestimated, and we are glad to find the authors of both papers directing special attention to it. As regards the minimum number of trees, etc., each plot should contain, Mr. Spencer Pickering states that, judging from the results obtained at Woburn, the number may be placed at six to twelve for fruit trees, twenty to fifty for bush fruits, and 100 to 200 for strawberries. Stated thus briefly, the latitude indicated by the figures given appears to be too great, but in the paper it is pointed out such an estimate requires many qualifications, and several are given. In referring to the experimental errors in connection with the experimental culture of hardy fruits, special mention is made of those arising from the number of varieties, method of pruning, length of life of the trees, and the measurement of results, and much valuable information given on the best method of avoiding them. The two papers to which we have specially referred are equally deserving of the careful attention of both the experimentalist and the practical cultivator, for while assisting the one in the conduct of his experiments, they will show the other how necessary it is not to readily accept results of experiments unless they are known to have been obtained under conditions favourable to the elimination of error.

Mr. George Barker, whose portrait we give herewith, is one of the many cultivators of chrysanthemums who, by the success they achieve in the production and exhibition of specimen blooms, assist in a marked manner in maintaining the traditional standard of these flowers at the provincial shows. Mr. Barker is equally at home in all departments of the garden, as evidenced by the high keeping that characterises the gardens of Hill House, Saffron Walden, the residence of Miss Gibson; but he has given special attention to chrysanthemums, and, as the result of his success in their cultivation, is a formidable competitor at the exhibitions at which he takes part. For some years he has exhibited both Japanese and incurved varieties with such remarkable success that in the several open classes, it is seldom that he occupies other than the first place in any one of them. This year he surpassed himself, and at the Cambridge Chrysanthemum Society's Show staged blooms of Japanese varieties that have certainly not been surpassed, if, indeed, they have been equalled, in this or any other year. We were specially interested in the incurved blooms that Mr. Barker staged both on boards and in vases, for while of large size, they were so perfect in every respect as to remind us of the superbly finished incurved blooms that were staged by the late Mr. E. Sanderson, so long the president of the National Chrysanthemum Society, and Mr. E. Molyneux in the days when the distinguishing characteristics of the incurved blooms were properly recognised.

Honour to Mr. J. Hudson, V.M.H.—At the meeting of the Council of the Royal Horticultural Society, held on November 21, the secretary drew attention to the marvellous exhibit of fig trees made by Mr. J. Hudson, V.M.H., in the lecture room on November 14, for the purpose of illustrating his lecture on the cultivation of figs in pots. The views expressed by the secretary were confirmed by the president and several members of the Council, and it was proposed by the president and seconded by Sir Albert Rollit, D.L., and carried unanimously that a Lindley Medal for cultivation be awarded to Mr. Hudson. The honour thus conferred upon Mr. Hudson was well deserved, for no such remarkable examples of the culture of figs in pots has yet been presented to public notice. Mr. Hudson contributed to the Gardeners' Magazine of October 7 an article in which he described the method by which he has obtained such splendid results in this phase of fruit culture, and the article was accompanied by an illustration of one of the span-roof houses that are devoted to fig trees in pots in the gardens of Gunnersbury House and of a tree of White Ischia. This tree is remarkable from the fact that, although it had been raised from a cutting only eight months previous to the photograph being taken, it was four feet in diameter, and carrying a full crop, some of the fruits being ripe.

Horticultural Club.—The next house dinner of the Horticultural Club will take place on Tuesday next, the 5th inst., at Hotel Windsor, Victoria Street, when Mr. Arthur W. Sutton, J.P., V.M.H., will give a lecture entitled "Four Hundred Miles on Horseback East and West of the Jordan." The lecture will be illustrated by one hundred painted views of Lebanon, Gilead, Basham, Moab, and Southern Palestine.

The Perpetual-flowering Carnation Society. — Next week, so generally known as "Smithfield Show Week," will afford an opportunity for many to visit London at a lessened cost by means of the extra trains that have been arranged at reduced fares, and those who are interested in horticulture will be able to visit two flower shows. One of these will be the exhibition of the Perpetual-flowering Carnation Society at the gardens of the Royal Botanic Society, Regents Park, on Tuesday and Wednesday, the 5th and 6th inst., and the other the Royal Horticultural Society's show at Vincent Square on the 5th inst. The new section D in the schedule of the carnation show is unique, as amateurs residing 50 miles and upwards from London may send their blooms to the place of exhibition, and have them staged by the society.

A Fine Cattleya labiata.—A finely-flowered example of this old species was exhibited at York recently by Mr. Taylor, gardener to Sir J. Ramsden, Byram Hall, Pontefract. The plant carried thirty-one blooms, the whole of which were expanded, except three. It was evidence of the skill exercised by Mr. Taylor in the management of this orchid, and the judges showed their appreciation by awarding a special cultural commendation.

Export of Fruit from Ireland.—It is interesting to read that, while five years ago the value of the fruit sent from Ireland to Great Britain did not exceed £30,000, it was £130,000 last year. This statement reminds us of the period—and that not so far distant—when fruit of Irish growth was practically unknown in England or Scotland, and the production of really good crops of the hardy kinds in Ireland was generally regarded as practically impossible. When, some twenty-two years ago, Mr. Lewis Castle and Mr. George Gordon, V.M.H., paid a visit to Ireland as a deputation from the British Fruit Growers' Association, for the purpose of enquiring into the condition of fruit-growing in that country, and suggesting the adoption of improved methods of procedure, the Irish markets were largely dependent upon Scotland for their supplies of gooseberries. In those days the climate and soil were regarded as quite unsuitable for the production of crops of apples and other hardy fruits of high quality, except by a few horticulturists resident in the country; and the views expressed by the members of the deputation in the course of their tour with reference to the possibilities of fruit culture in Ireland were regarded with a considerable amount of scepticism. The same feeling obtained on this side of the Irish Channel; for, when Mr. Gordon presented a report on the investigations to a conference of fruit growers held at the Crystal Palace, the conclusions were by no means accepted with unanimity. Moreover a considerable proportion of the one hundred and eighty newspapers that devoted leaders to the questions raised in the report described the conclusions as far too optimistic. As the results have proved, the case in favour of Ireland as a fruit-producing country was really understated. Within a few years of the visit of the deputation the Agricultural Department of the Irish Government gave serious attention to the educational side of fruit culture, and all concerned entered so heartily into the carrying out of the scheme that an enormous improvement has been effected in all parts of the country.

Glasnevin Botanic Gardens, as in the case of so many other parks and gardens in various parts of the United Kingdom that are open to the public, have had their exhibition of chrysanthemums. The plants are arranged in a spacious glass structure near the entrance, and the large number of finely-developed blooms have proved highly attractive to the large number of citizens of Dublin, by whom the exhibition has been visited since it was opened. Sir F. Moore, V.M.H., and his staff may be heartily congratulated on the high quality of the flowers and the taste evinced in the arrangements.

Roses at the Durbar Camp.—The wonderful White City at Delhi, composed of about 150,000 tents, and covering about 25 square miles, will be itself one of the great features of the Durbar, at which the King is to be crownedEmperor of India. Needless to say, green lawns and gay gardens have been arranged, and round the King's Camp great beds of roses have been planted near the Queen's tents, and it is reported that about £1,000 have been spent on this particular feature.

A Daffodil Show for London in 1912.—We have received a copy of the schedule of prizes to be offered on April 16 and 17 next, at the Royal Horticultural Society's Daffodil Show. The classes, 45 in all, are grouped into four divisions, two of which are open to all, and two for amateurs. The division for seedling and new daffodils appears to be specially well arranged, and should result in an excellent and interesting competition. With the schedule is sent a letter, which reads: "In the spring of 1911, as so many daffodil lovers expressed a wish that a two-days' exhibition of daffodils might be held in London in mid-April, the Royal Horticultural Society's Narcissus Committee approached the Council of the society upon the matter. The Council favoured the movement, and the committee then appointed Mr. E. A. Bowles, Mr. P. R. Barr, Mr. W. B. Cranfield, Rev. G. H. Engleheart, Mr. Robert Sydenham, Mr Walter T. Ware, and Mr. C. H. Curtis to prepare a schedule for the exhibition, and consider ways and means. A schedule has been prepared and approved, and a copy is sent herewith. The Council of the Royal Horticultural Society have promised to give the cups and medals offered as prizes, but the cash prizes must be provided by daffodil lovers. We have made ourselves responsible to the Council for these cash awards, and now confidently appeal to all interested in daffodil culture for generous support." This is signed on behalf of the Narcissus Committee by E. A. Bowles (chairman), Myddelton House, Waltham Cross; C. H. Curtis, (hon. secretary), Adelaide Road, Brentford; and Walter T. Ware (treasurer), Inglescombe Nurseries, Bath; and there is a footnote asking that all donations to the prize fund be sent direct to the treasurer, Mr. Walter T. Ware.

School Gardening.—The President of the Board of Education recently stated in the House of Commons that, so far as the Board of Education had figures on the subject, the number of school gardens had increased from 379 in 1902-3 to 1,880 in 1909-10. The number of scholars in respect of whom the special grant for gardening was paid was 5,501 in 1902-3 and 27.679 in 1909-10. Full returns for the years just elapsed were not yet available, but it was believed that the number of schools giving practical instruction in gardening must have been upwards of 2,000.

Sir Thomas Fowell Buxton, who was presented on Tuesday last with a testimonial in recognition of his long service as chairman of the magistracy for the Epping Division, has been Verderer of Epping Forest since 1878, and during this long period has rendered a service of much value in connection with this fine open space.

Mr. W. Rigby, gardener to the Rev. A. C. Cooper-Marsdin, Birkley, specially distinguished himself at the remarkably fine exhibition recently held by the Bromley Chrysanthemum Society. He was successful in winning the challenge cup for six vases of Japanese varieties, and seven other first prizes. Mr. Rigby's success is of special interest from the fact that in the management of the garden of which he has charge, he is single-handed.

An Old English Rose Garden for Battersea Park.—At a recent meeting of the Parks and Open Spaces Committee of the London County Council, it was decided to convert the Botanical Garden at Battersea Park into an Old English Garden at a cost not exceeding £265. This alteration is an outcome of the great success and appreciation of similar Old English gardens made in other parks under the care of the London County Council.

Reversion of Rose.—In a communication to the Paris Academy of Sciences, M. J. Violle states that a plant of Gloire de Dijon rose, which during the past twelve years had borne large numbers of the usual double flowers suddenly, in September, produced on all its branches single blooms. Eight days later these were followed by double roses. The production of a crop of single blooms is attributed to the effects of the hot and dry weather that was experienced in France during the past summer.

Perthshire Sweet Pea Society.—We are pleased to learn that the operations of this society during the past year was attended with a full measure of success. At the annual meeting of the society, Mr. R. S. Halley, the secretary, in submitting the report, stated that the enthusiasm of the members was unabated. At the end of last year the number of members was one hundred and forty-four and now the members number two hundred and one. Mr. A. M. Mechie, the treasurer, reported that the financial results had been such as to enable the executive to meet the whole of the expenditure for the past year, and to reduce the debit balance at the close of 1910 by £6 13s. The Rev. Harold Mayall, president; Mr. R. S. Halley, secretary; and Mr. F. M. Mechie, were reelected. At the conclusion of the business meeting Mr. J. Griqor, Forres, gave a lecture on the cultivation of sweet peas.

Cider Sickness, which is sufficiently prevalent in the cider-producing counties of England to inflict considerable losses upon the makers of this beverage, has been investigated by Messrs. B. T. P. Barker and V. F. Hill, and the results of their investigations were embodied in a paper read at a meeting of the Agricultural Sub-Section of the British Association. This "sickness" makes its appearance in ciders early in the summer, and the first symptoms of the attack are a characteristic frothing of the liquor and a sudden and violent evolution of gas. It was found that the pleasant fruity character of the cider disappeared, and a peculiar and disagreeable odour and taste were produced. After a short time the cider generally became tainted, and suffered a loss of colour, and in some cases the turbidity increased until the liquor attained a thick milky condition, while in other instances the cider itself remained comparatively clear, but a considerable deposit was precipitated. The specific gravity of the cider fell rapidly during sickness, owing to the destruction of the sugar, and the percentage of alcohol was also increased. Ciders most liable to sickness are those containing relatively large amounts of unfermented sugar, and generally those of best quality. Perry is also liable to the same trouble. It has been found possible to effect the isolation of a bacterium which could produce all the symptoms of sickness in sterilised ciders and perry infected with pure cultures of it. The most promising measures for combating the disorder were found to be the sterilisation of all vessels and appliances which had been contaminated with sick cider, storage at a low temperature, and suitable blending of ciders to raise the acidity above 0.5 per cent. malic acid, and to give a moderately rapid normal rate of fermentation. It had also been observed that ciders liable to the disorder would escape if bottled very early in the season, whereas if bottled at the usual period they quickly turn sick.

Mr. S. Mangham, formerly Frank Smart student in botany at Cambridge, has been appointed lecturer in botany at Armstrong College (University of Durham).

"**Jardinage.**"—A new monthly periodical devoted to gardening, and printed in French, under the editorial management of our old friend and colleague, M. Georges Truffaut, of Versailles, has just reached us. The style and get-up of the work generally is of a high order of merit, for the printing is clear and well executed, the illustrations are excellent work in photographic reproduction, the cover is done in colour, and altogether the new monthly promises to be artistic, practical, and interesting. The authors who contribute to the first number comprise Messrs. Georges Truffaut, Jules Vacherot, Ph. de Vilmorin, and Georges Bellair. The subscription outside France is six francs per annum, and the office of our new confrère, to whom we wish success is 90 bis, Avenue de Paris, Versailles.

Chrysanthemums at Harrogate.—Chrysanthemums are grown with much success in the gardens of Belvedere, Harrogate, the residence of Lord Faber, who, a few days since, opened the houses in which they were arranged to the public. Many of the residents and visitors availed themselves of Lord Faber's generosity, and fully enjoyed the display of finely-developed blooms.

APHELANDRAS.

The aphelandras are, taken altogether, an exceedingly floriferous genus of acanthaceous plants that require the temperature of a stove, or, at all events, that of an intermediate house. They are principally natives of the southern portion of Mexico on to Brazil, and all have flowers of some shade of yellow or scarlet.

These blossoms are borne in a decussate spike-like head, each flower being, in most cases, subtended by a large bract, which, in some instances, is almost, if not quite, as showy as the flower itself. The individual blooms do not remain long, but a succession is kept up from one head for a considerable time. Added to this, the foliage of some of them is remarkably handsome, the course of the midrib and principal veins being boldly marked in white or yellow.

Like many other acanthads, such as jacobinias and eranthemums, the aphelandras are of a soft shrubby nature, and are readily struck from cuttings of the young shoots. Half a dozen species or so may be met with in general cultivation, but there are many more than this.

The showiest and best known kinds which can generally be obtained from nurseries are:

Aphelandra aurantiaca.—A very free-flowering species, introduced from Mexico in 1844. The leaves are dark green, ovate, and wavy at the margins, while the flowers are comparatively large and of a dazzling orange-scarlet colour. Examples little more than a foot high will often bloom. Of this height one-half, or nearly so, will consist of the erect spike. There is a variety, Roezli, which differs from the type in the leaves being shaded with white.

A. Blanchetiana.—A stout, erect-growing species, which will in time become almost woody in character. The leaves, which are comparatively narrow, have the midrib and principal veins marked in silvery-grey. The bracts are reddish, while the flowers are yellow. This species is more liable than aphelandras in general to become bare at the base. It is also known as A. amœna, under which name it was first distributed twenty-one years ago.

A. Chamissoniana.—Like the preceding this was sent out under a different name to that which it now bears, for when put into commerce in 1881 it was as Aphelandra punctata. The sturdy, erect stem of this species is clothed with leaves from four to six inches long, elliptic in shape, with the course of the midrib and principal veins marked with a broad white band, breaking off at the edges into dots or freckles of that hue. The ground colour of the leaf being deep green, these light-coloured markings stand out conspicuously. The large bracts which go to form a cone-like head are deeply serrated at the edges, and in colour are a deep chrome-yellow, shaded with green towards the base. The individual flowers are of a curved tubular shape, about one and a-half inches long, and of a rather lighter shade of yellow than the bracts. These last retain their colouring long after the flowers have faded.

A. Fascinator.—The ovate acuminate leaves of this species are of a bright olive-green, marked with stripes of clear silvery-white, while the undersides are of a purplish-violet tint. The flowers are of a brilliant scarlet tint. A native of Colombia, Aphelandra Fascinator was first introduced in 1874.

A. Margaritæ.—A notable feature of this species is the pubescent character of the leaves, which are about six inches long and a couple of inches in width, olive-green above and purplish underneath. The main veins are marked out in white, and the orange-coloured flowers are very conspicuous. It was introduced from Brazil about a quarter of a century ago.

A. nitens.—The specific name of this is derived from the exceedingly glossy, almost varnished, surface of the leaves, which are of a deep bronzy-green on the upper side and purple beneath. They are oblong, about six inches long and three inches broad, and are leathery in texture. The flowers, borne in a narrower spike than some of the others, are large, and of a bright scarlet colour When at its best, in the depth of winter, as often happens, this aphelandra is particularly effective. It was found and introduced by Richard Pearce, when travelling in South America, and first flowered at Chelsea in 1868.

A. pumila.—This well merits the specific name of pumila, as the plant is of a decidedly humble stature, the entire specimen, stem, flower spike, and all, being often considerably less than a foot in height. The oblong-shaped leaves, cordate at the base, are comparatively large, while the curved orange-scarlet coloured flowers extend considerably beyond the dull-tinted bracts.

A. squarrosa.—In vigorous examples the elliptic-shaped leaves of this species are nearly a foot in length, and the flowers and bracts are deep yellow. There is a variety, Leopoldi, whose leaves have the principal veins clearly marked with ivory-white. In this the flowers are yellow, but the bracts are often tinged with red. This variety has been grown in our gardens for over fifty years, but in 1887 it was again sent out under the name of Aphelandra chrysops.

A. tetragona.—The oldest, and certainly one of the finest, of the entire genus. It is of rather tall growth, and is seen at its best in pots from six inches to eight inches in diameter. Under such conditions it will reach a height of three feet to four feet, the stout, erect stem being clothed with large broadly ovate leaves, and terminated by a head of scarlet blossoms. Most aphelandras have the flowers disposed in a simple terminal spike, but this species has, in addition, four supplementary spikes at the base of the principal one, thus giving to this species a very distinct appearance, and suggesting the specific name of cristata, by which it was formerly known. It is at different periods of the year very effective in the T range at Kew. Most authorities, including Colonel Beddome, give Aphelandra tetragona as a native of the West Indies, but in the "Kew Hand List" it is stated to be from Colombia. It was introduced as long ago as 1733.

The propagation of aphelandras is not at all a difficult matter, as cuttings of the young shoots root readily at any time during the growing season, that is if put into pots of sandy soil, and placed in a close propagating case in the stove; if with gentle bottom heat so much the better. If possible, stout, or fairly stout shoots should be chosen for the cuttings, as the weak ones do not produce as fine heads of blossoms. For this reason it is not desirable to stop the growing plants, and cause them to break out into two or more shoots, as the display is not equal to that furnished by one good head. Effective plants of the smaller growers may be produced in pots four inches to four and a-half inches in diameter, and if a good show is required from three to five of these flowering plants may be grouped in a large deep pan. Aphelandra aurantiaca, Aphelandra nitens and Aphelandra pumila are particularly amenable to this mode of treatment. W. T.

CIDER APPLES.

Your recent note on the report issued by the National Fruit and Cider Institute is interesting. I have often wondered why the small apples of ordinary varieties could not be utilised; now I see why many cannot be profitably employed. When at the Brewery Exhibition, recently held in the Agricultural Hall, I saw the judges at work examining the various exhibits in the cider classes, and noted the many points to be taken into consideration in arriving at a just decision. I could not but come to the conclusion that there is much more art required in producing good cider than is generally thought. The right kind of apple plays an important part in the production of the finest type of cider. At the Brewers' Exhibition prizes were offered for collections of cider apples, of which a goodly number were staged; their attractive appearance prompted me to jot down the names of the most prominent looking varieties. Many of them were richly coloured. Dr. Hogg, in his "Fruit Manual," mentions over fifty varieties of cider apples, but I cannot find any other authority dealing with them at all; few nurserymen include them in their apple lists; therefore one is forced to the conclusion that cider apple trees are not much in demand, and, judging from the appearance of many orchards, there does not appear to have been much planting done in recent years, although it was said at the show much planting is now being done.

The following varieties I noted in the class for thirty-six varieties: Sweet Harcourt, White Close, Jartigten Mill, Royal Jersey, George James, Port Wine, Cup and Liberty, Cider Quarrendon, Cadbury, Cider Spice, Pomroy, Hobb's Jersey, White Jersey, Hay Masters, Dan's Favourite, Kingston Black, Law's Crab, Comane Red, New and Old Foxwhelp, Cherry Pearmain, and Handsome Hereford. E. Molyneux.

NEWCASTLE FLOWER SHOW.

As a member of the society which is responsible for the Newcastle Flower Show, I desire to bring forward a matter which concerns not only the society itself, but also the public at large. The actual name of the society is the Northumberland, Durham, and Newcastle-upon-Tyne Botanical and Horticultural Society. It is not the oldest society in the North of England, but it is certainly one of the oldest. Now does it live up to its name? What does it do to justify such a title? Nothing at present, except a flower show once a year. And the serious aspect of the matter is that the society is £400 in debt, and cannot evidently get out of debt. What is to be done for we cannot stand by and see this old society go down? I suggest:

1. That a public meeting be called as soon as possible. That all horticultural societies in the two North-Eastern Counties be asked to send delegates.

2. That new blood be infused into the committee. There is no lack of keen horticulturists in the district.

3. That the society co-operate with the North of England Horticultural Society. This latter society has been brought into existence with the goodwill and support of the Royal Horticultural Society and cooperates with them in the North of England.

4. That it be clearly understood that the society live up to its name, and lead the two North-Eastern Counties in all that appertains to horticulture (educational, scientific, commercial, and general).

5. Personally I would suggest that as soon as the deficit is cleared off, a large spring show be held each May in Newcastle, and that all the profits be given to the hospitals. Speaking for the N.E.H.S. we will gladly do all we can to restore this old society to its former position and back it up in its work.

J. Bernard Hall.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE, November 21.

Present: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair), and Dr. J. A. Voelcker, Rev. Canon Fowler, Messrs. J. O'Brien, A. Worsley, W. Hales, J. T. Bennett-Pöe, W. C. Worsdell, E. M. Holmes, W. Cuthbertson, and F. J. Chittenden (hon. secretary).

RASPBERRY BEETLES. — The Rev. Canon Fowler showed specimens of the raspberry beetle, Bytums tomentosus, which feeds in the flowers of raspberry, blackberry, loganberry, and strawberry, and remarked that in all probability the pest pupates in the soil, not so much in old stems, etc. He considered that if some measure of reaching the pest in the soil could be devised it would prove very beneficial, but after some discussion the committee thought that none of the methods at present economically available would be entirely suitable in the present instance. It was remarked that some success had been attained in dealing with this pest by shaking the canes over tarred boards and by spraying with lead arsenate during the time the plants were in bloom.

UNCOMMON FRUITS. — A. Bayldon Esq., sent from Dawlish, Devon, a bunch of about sixteen fruits (on one branch) of Mandevilla suaveolens, and a pair which measured twenty inches in length; a bunch of seed pods of Wistaria japonica from a standard on its own roots which bore several dozen fruits (W. multijuga was also fruiting in the same garden, and had produced racemes 30 inches to 36 inches in length); a spray of many fruits of Cornus capitata (Benthamia fragifera) from a very old tree 26 feet in height. The seeds of the last are picked from the fallen fruit by the blackbirds and dropped about the grounds. R. Shafto Adair, Esq., of Clauville, Minehead, Somerset, sent two excellent fruits of the common pomegranate, perfectly ripe, and open to show the seeds, picked from a plant growing on a south wall.

Mr. A. S. Horne, B.Sc., of the Wisley Laboratory, exhibited specimens in illustration of the following notes:

STREAK DISEASE IN POTATO. — In 1910 a sample of seed potatoes of the Duke of York variety was obtained from a dealer in the North of England. When the tubers were examined, about 20 per cent. of them were found to be affected with streak disease. Several diseased tubers, however, were not included in the estimate. These were rotten in the middle, and the flesh was more or less excavated, the cavity or cavities being enclosed by diseased tissue. It was supposed at the time that this condition was due to some other cause. During November, 1911, however, a complete series of stages has been obtained between streaked and rotten tubers of the same variety of potato. The following stages in the development of streak disease in the Duke of York variety are sent for inspection:

1. Potatoes marked internally with streaks as described in the "Journal of Agricultural Science," iii., September, 1910.

2. Potatoes with internal brown rot. Upon closely inspecting the flesh the rotten area is seen to be made up of a number of concentric curved brown lines; the rotten appearance is due to the fact that the lines are very numerous, and almost in contact with one another. The lines show up well when a slice of the potato is soaked in potash.

3. Potatoes with cavities in the flesh which are bounded by a brown zone of diseased tissue.

4. Potatoes similarly diseased, but having external injuries.

The diseased potatoes were raised in Scotland with the co-operation of Mr. W. G. McGowan in connection with pototo investigations, of which an account has not yet been published. The seed potatoes of the Duke of York variety were obtained from a locality in which streak disease is at present unknown, and were free from disease when planted.

SPECIMEN TREES FOR PARKS AND GARDENS.

(Continued from page 856.)

Nyssa, Catalpa, etc.

In the South of England Nyssa sylvatica is unsurpassed for colour in autumn. The tree is one of the first to assume its autumn garb, quite early in September, the rich scarlet leaves, remaining in good condition for a month, or even longer. This is a North American species of medium height, 40 feet to 50 feet is given as the average, but, so far as I am aware, the few trees there are in this country are nothing near this height at present. Magnolia acuminata (the Cucumber Tree) forms a large specimen, with conspicuous leaves eight to ten inches in length. The flowers are green, tinged with yellow, but these are not nearly so striking as those of the Yulan (M. conspicua and M. Soulangeana), which in the south and west are unrivalled as spring-flowering trees for the pleasure grounds. The first-named has pure white fragrant blossoms, and M. Soulangeana rosy-purple flowers. Both form shapely round-headed specimens, attaining, with age, to a height of 20 feet or more. There is a specimen of the cucumber tree at Syon House, Middlesex, 51 feet in height. The same garden also possesses a very fine specimen of the Sweet Gum (Liquidamber styraciflua). This tree exceeds 90 feet in height, and is reputed to be the largest specimen in the country. Small trees are listed at half-a-crown by nurserymen, which serves to show that it is easy to obtain. The foliage in autumn turns a pleasing mixture of green and red, with sometimes a splash of yellow.

A REMARKABLE SPECIMEN OF THE HOLM OAK (QUERCUS ILEX) AT KEW.

When in full flower, in August, the Indian Bean (Catalpa bignonioides) is a magnificent spectacle, which, at a distance, might be mistaken by the ordinary individual for a horse chestnut. The leaves are large, cordate; the flowers white, with yellow and purple blotches in the throat; in autumn the trees are laden, that is assuming they have flowered freely, with long bean-like fruits. The variety aurea has rich yellow leaves, and forms a very suitable specimen for use among large trees planted for colour effects. Corylus colurna, the Constantinople Hazel, is a very fine ornamental tree. Several specimens in this country exceed 80 feet in height. The most ornamental walnut we possess is Juglans nigra, the black walnut of North America. This tree, 80 feet to 100 feet or more in height, far surpasses in beauty the common Walnut (J. regia). J. Sieboldiana is promising as a young tree. The Flowering or Manna Ash (Fraxinus ornus) is generally met with as a well-furnished round-headed tree of moderate size. It is very ornamental when in flower, and also interesting in autumn when loaded with clusters of seed pods.

Maidenhair Tree and Golden Larch.

The reason why the Maidenhair Tree (Ginkgo (Salisburia) biloba) is not more generally planted is difficult to understand. During recent years notes concerning it have from time to time appeared in the horticultural Press, but it is only occasionally that one sees young trees that have been recently planted. We have no other tree like it, and as a specimen the maidenhair tree is unsurpassed. Tall and graceful in outline, there is a charm surrounding it which cannot fittingly be described on paper. The rich green fern-like leaves change in autumn to a pleasing yellow tint. During winter, when devoid of leaves, the tall, erect branches, and smaller horizontal growths, are the distinguishing features of this tree. The maidenhair tree is represented at Frogmore and Kew by magnificent specimens, both of which exceed 60 feet in height. There is only one fault to find with this tree, and that is its rather slow growth. Particular interest is attached to the ginkgo botanically, as it is one of the few deciduous genera of Coniferæ, and the male and female flowers are borne on different trees.

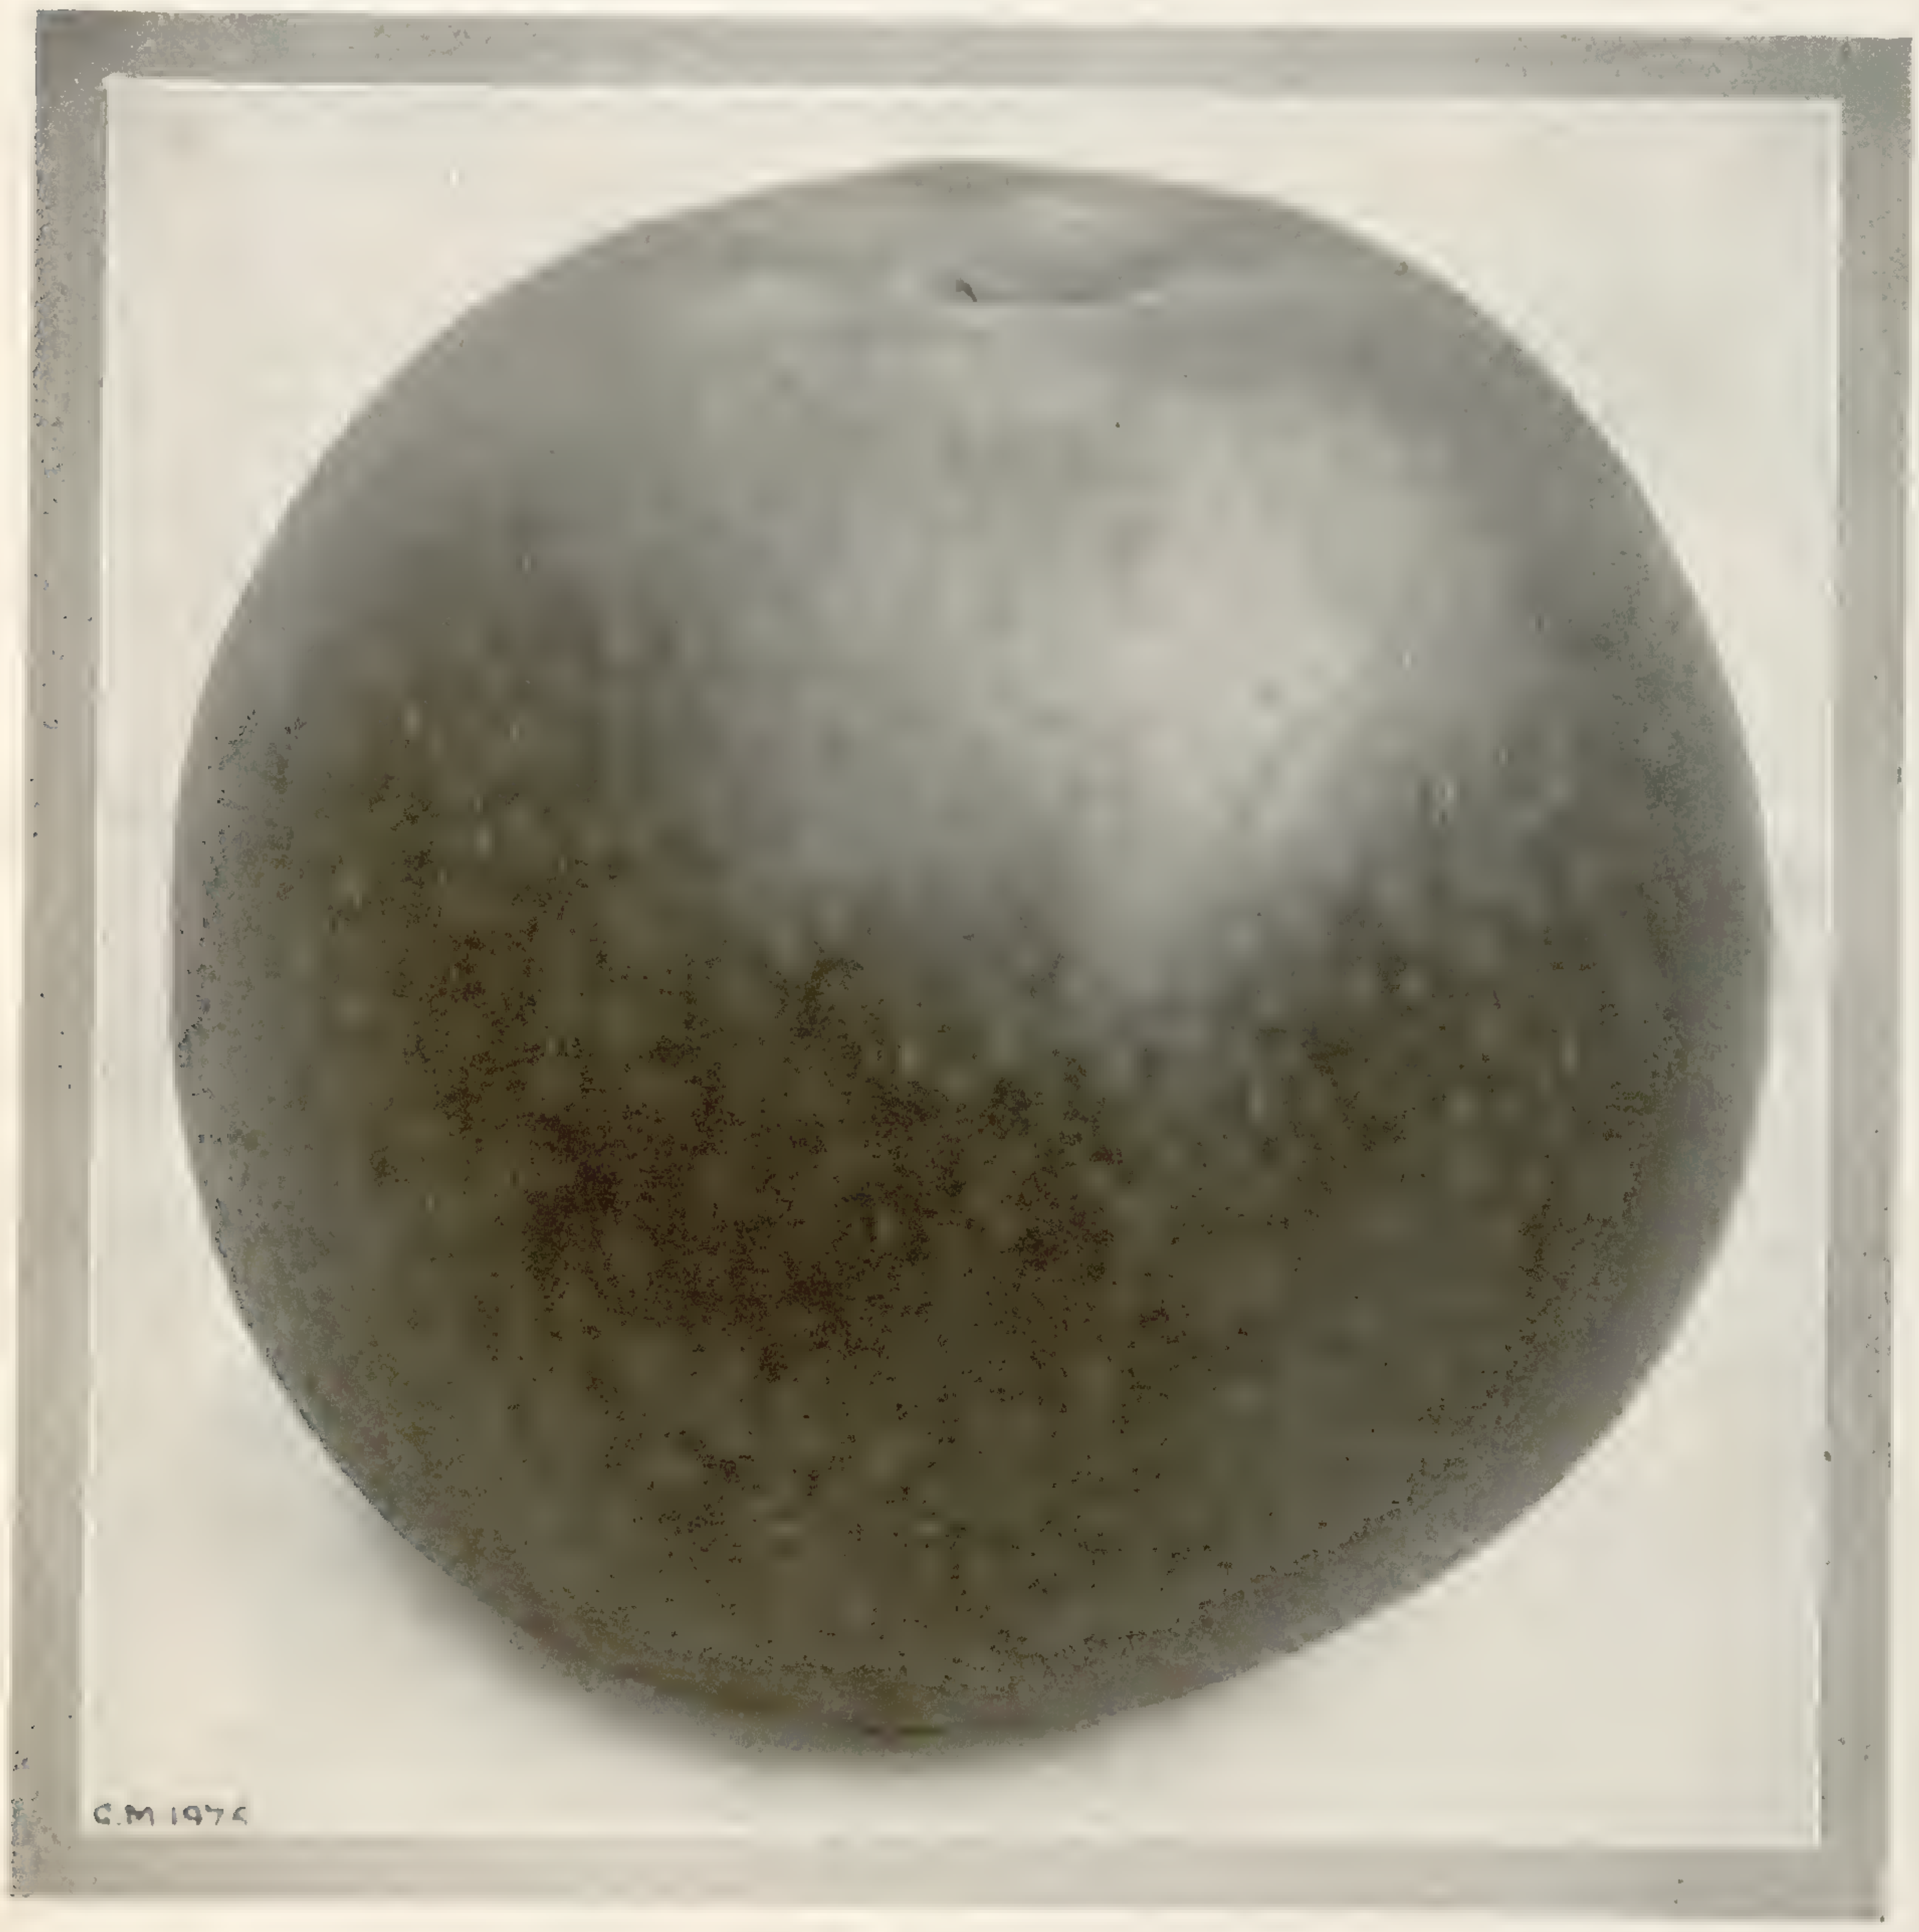
A second deciduous conifer which promises well is Pseudalarix Fortunei (Kæmpferi), the Golden Larch of China, so named on account of the foliage, which turns a rich golden-yellow in autumn. In general appearance the tree resembles a sturdy specimen of larch. Specimens exist in China over 100 feet in height. A tree 18 feet high, at Kew, bears cones freely. For planting in damp positions, and along the margins of water, the Deciduous Cypress (Taxodium distichum) is most useful, and it colours an attractive shade of brown in autumn.

Sophoras and Ailanthus.

Sophora japonica is especially worthy of attention, as, so far as I am aware, it is the latest large tree to flower in August and September, being later than the catalpa. This year the acacia-like leaves were hidden by myriads of creamy-white flowers, and when these were falling it was possible to rake them up under the trees like so much chaff. Now, on the last day of October, when most of the trees have shed, or are fast shedding their leaves, the sophora trees are as green as they were at midsummer. The Tree of Heaven (Ailanthus glandulosa) is a fast-growing tree in a young state, with large pinnate leaves; 50 feet to 70 feet is a common height for this tree. The bunches of orange-tinted fruits, dotted freely over the trees, are conspicuous in autumn, although in summer the flowers are so small that unless closely looked for they would escape notice.

Pendulous, or Weeping Trees.

Trees with pendulous branches form a pleasing change from those of normal growth. Their free use, however, is not desirable; one here and there among other trees, by way of contrast, should be used. Select open positions for them, or, in the case of the weeping willow, plant by the lakeside or stream. In most private places the use of pendulous trees is restricted to the enclosed pleasure grounds, as cattle usually graze in the park. A fence could be put round them, but this would, to a great extent, mar their beauty, certainly more so than does a fence erected round trees of a normal habit of growth.



APPLE CORONATION.
A handsome dessert apple, raised by Mr. H.C. Prinsep, from Cox's Orange Pippin, and put into commerce by Messrs. J. Cheal and Sons, Crawley.

An important item in the care of weeping trees is to keep a branch tied up near the centre to form a leader, to increase their height. In old trees this is, of course, not of such great importance, as it is in young specimens. Another matter requiring attention is the lower branches. These should be kept just free from the grass, as the constant swaying of the branches would in time kill the grass, leaving a patch of bare earth exposed. Ten of the best weeping trees are the pendulous varieties of Betula alba, Prunus (Cerasus) Mahaleb, Crataegus oxyacantha, Fagus sylvatica and the variety purpurea; Fraxinus excelsior, Populus tremula, Salix babylonica (the type of this is weeping), Ulmus montana, and Ilex aquifolium, the last-named being the best of the weeping evergreens.

A. Osborne.

Kew.

SOME SPRING CROCUS SPECIES.

The species of crocus, as distinguished from the handsome named Dutch varieties and other forms derived mainly from C. vernus, are growing in popularity, and a few notes upon some of the best of those which bloom in spring may not be unacceptable, as they can still be planted.

They all require practically the same treatment, and will flourish in the soil, planted about two inches deep, either in the grass, in a border, or on rockwork, choosing a sunny situation and, as far as possible, shelter from strong winds and the driving rains of spring.

A pretty spring crocus is C. alatavicus, the Altai one, which has good-sized flowers of white when open, the outside being blue tinged with brown. Then one which is very early and should, possibly, have been planted ere now, is C. ancryensis, which is of a bright orange-yellow, and is more tender than others we have to our command. We may, therefore, substitute for it some of the forms of C. aureus, and the type, of a good yellow, is excellent and larger than C. ancryensis. There are several varieties of C. aureus, such as sulphureus pallidus, which is of a sulphur-yellow, with others which may be omitted until the beginner acquires a larger collection.

A bright and beautiful little yellow crocus, however, is C. Balansæ, which is a small-flowered variety with glowing orange flowers, daintily feathered with black.

A large and handsome crocus, not always obtainable true to name, a form of vernus sometimes being supplied for it, is C. banaticus, from the Banat, and having attractive flowers of purple, prettily edged with a kind of blackish purple.

In Crocus biflorus we have a species which gives us a lovely set of crocuses. The type is white, feathered with lilac, but there are also varieties of a soft lilac in the interior, and others which are coloured with buff outside. C. b. Pestallozoe is an exquisite thing with blooms of the daintiest size nestling among the grassy leaves. They are white. C. b. pusillus is white with an orange throat, and in the variety called Weldeni we have one with different shades and markings of soft blue. This, the Scotch crocus, is a fine and valuable species indeed, and much frequented by the bees. Crocus candidus is a handsome white species, and its variety sub-flavus has pale-yellow blooms.

The charming C. chrysanthus, which has yellow flowers, is one of the most variable of all. Two little forms, fusco-tinctus and fusco-lineatus, bloom very early, and give bonny little flowers of yellow, tinged and striped, as the case may be, with brown. The variety albidus is white, with a blue base; Canary Bird and superbus are lovely forms higher in price. The pretty C. etruscus is a most desirable little crocus also, with its white flowers lined with purple.

C. Fleischeri is not often seen, and has neat white, faintly-striped flowers among narrow grass-like leaves. Its fault is a lack of substance, but it is a dainty thing indeed.

Crocus Imperati must not be overlooked with its lovely lilac-purple flowers of good size, and buff feathered with purple outside, or pure buff on the exterior. It should be in every garden. C. Korolkowi is often attacked by slugs, but is charming with its orange flowers, decorated with deep brown outside. C. Olivieri is another yellow one; and C. reticulatus is a pretty species with white flowers striped with lilac. Crocus Sieberi, of a fine blue, is a charming little early crocus, now very cheap; stellaris is an old one with starry yellow flowers, striped with brown outside; and the old-time favourite, the Cloth of Gold one, C. susianus, is pretty when it opens its golden flowers.

Crocus Tommasinianus is a charming little species, varying in shade of lavender—almost into purple, and one of the easiest of all to grow; while the old Cloth of Silver one, C. versicolor, is cheap and useful to those who wish a variety with its lavender or purple flowers. Finally we have the very early one called Crocus vitellinus the Yolk-of-Egg crocus, whose popular name well indicates the colour of the pretty little blooms.

Besides these there are other species and varieties beloved of the enthusiast, who is ever on the search for new beauties to add to his garden among these exquisite crocuses, which do so much to give delight.

S. Arnott.

APPLE CORONATION.

An apple of great merit as a dessert variety for private gardens is Coronation, one that was raised by Mr. H. C. Prinsep when in charge of the Buxted Park Gardens. It is a seedling from Cox's Orange Pippin, and bears a good deal of likeness to its well-known parent. The fruits are rather above medium size, greenish-yellow, and heavily flushed with crimson on the sunny side, consequently it has a very attractive appearance. In flavour it is very crisp and pleasant, and very suggestive of Cox's Orange Pippin. The variety grows freely, and yet possesses a very compact habit, hence it is especially suitable for small gardens and also for orchard house culture in pots. Coronation received an Award of Merit from the Royal Horticultural Society on October 21, 1902, and it was distributed by Messrs. J. Cheal and Sons, Crawley.

Veronica Silver Queen. — We have long been familiar with the clearly variegated Veronica Andersoni variegata, from which the variety Silver Queen is a decided break. It has a free branching habit of growth, and the leaves are very plentifully variegated with cream-white. It appears likely to be of value for furnishing window boxes and similar purposes.—W. T.

SHRUBBY DECIDUOUS CLIMBERS.

With the wealth of beauty we now have in climbing plants of a shrubby character there is not much excuse for having bare walls, fences, or screens, especially when any of these are of an objectionable character. Most climbing plants of this class are not fastidious, in a cultural sense; they grow freely with ordinary attention and a suitable site. Even if there are no walls or screens to cover, a fine effect is assured by growing many of these plants on poles in the shrubberies, on lawns, or trailing them over pergolas or chains.

Pole specimens of a suitable character give a bold effect in a shrubbery harmonising so well with the regular occupants if judiciously chosen to contrast favourably with the subjects about their base. Trained up suitable poles, at least twelve feet high, many subjects can be cultivated that otherwise could not be entertained where wall space is unavailable. If the soil is of an ordinary character the preparation of the site is simple; deeply digging and adding half-decayed manure at planting time is all that is necessary. What we usually find at the base of new walls are shavings, broken bricks, and chunks of wood; all these should be removed two feet deep, and as many feet wide, putting in their place a compost of good garden soil (fresh loam is preferred), enriched with stable manure. In the case of clay soil some drainage is an advantage as stagnation about the roots is objectionable; an addition of leaf-mould, road grit, decayed vegetable matter, will render the soil more porous, and promote a rapid growth.

The early and regular training of the shoots will ensure a regularity of covering whether it be on a wall, screen, or pole; when the shoots are allowed to become crowded through want of attention they are most difficult to disentangle without injury. An abundant supply of moisture at the roots, and copious syringings overhead in evenings, after hot dry days, will do much to accelerate growth.

The following are suitable deciduous subjects, and not at all difficult to manage. The finest of all the vines is Vitis Thunbergi, this growing more vigorously than any other sort. In the autumn the leaves change to yellow, red, and, at times, crimson. V. Coignetiæ grows freely, giving, during the summer, huge deep green leaves with an underside of pale buff yellow. In soil of a light character this assumes brilliant colouring of yellow and crimson in the autumn, but here, in stiff soil, it does not change to these pleasing tints. V. flexuosa Wilsoni is a distinct form, of much ornamental value, and the small leaves assume a deep bronzy hue, while the undersurface is a bright purple. V. armata Veitchi has medium-sized leaves, and a neat habit of growth, and in the autumn is a rich crimson. V. vinifera purpurea, known as the purple-leaved vine, is still one of the most beautiful. This season it is especially richly coloured.

Actinidia arguta is a rapid-growing climber that makes a capital pole plant, entwining around its support quite easily; during summer the leaves are deep green, and in the autumn a rich golden-yellow. Akebia quinata is most interesting, especially against a high east wall, where it grows freely and flowers abundantly in April and May. The peculiarly-shaped clared-coloured flowers are richly perfumed. When once this plant has covered its allotted space, and not too thickly, spurs should be encouraged to form on the main branches by pinching the growths several times during the summer. From these spurs an abundant flower crop will be annually obtained.

Ampelopsis Veitchi is too well known to need more than mention, but A. Henryi is not so well known. In growth it resembles the Virginian creeper, though it is less vigorous. The leaves have down the centre of each part a band of silver, which, in the autumn, assumes a purple hue, the whole changing to bright red later on. Aristolochia sipho cannot be omitted, as its handsome deep green leaves are appreciated during the summer. It grows well in any site—wall, pergola, pole, or elsewhere. The leaves change to deep gold in the autumn. Jasminium primulinum is a great advance on J. nudiflorum, producing bright yellow flowers if grown against a wall in a sheltered site; unfortunately, it is not quite hardy, but, being such a pleasing subject, it is worth taking a little pains to shelter it from severe frost.

CHRYSANTHEMUM YELLOW CAP.

A yellow variety of Caprice du Printemps, as grown and exhibited by Messrs. Jas. Veitch and Sons, Chelsea.

Much difficulty is sometimes experienced in obtaining suitable flowering plants for a north wall. Kerria japonica flore plena is a capital subject for such a wall, twenty feet high, if required. Treat the plant liberally, using manure freely in the soil at planting time, and encouraging it to grow freely; secure the shoots to the wall when growth is fully made, and a close covering will thus be obtained, and a full flower crop will result each year. Polygonum Baldschuanicum is one of the finest of summer-flowering plants we have; it is of quick growth, and fine for poles, pergola, or a wall, and it is especially suitable where its long, graceful shoots show to advantage.

The Rubus family provides many ornamental species. R. biflorus has green leaves, the stems being covered with silver bark, which, in the autumn, when the leaves have fallen, is attractive. R. bambusarum has small, drooping, green leaves with glaucous stems. Bignonia grandiflora and B. radicans are most desirable, particularly where a south wall can be given them; here they flower so much more freely than in the open, although at times they blossom abundantly on the pergola. Cotoneaster Simonsi is not nearly enough planted against walls; here its brilliant red berries are much more freely produced in the open.

Clematis of the various sections cannot be omitted from any list of shrubby climbers; C. montana is the first to flower, either on a wall or pergola, and C. flammula the latest; both are highly perfumed, and usually flower in great profusion. Amongst garden hybrids there are abundant sorts to select from, and C. Jackmani and its white form are still desirable. For a great variety of positions none can equal the purple colour of the former, no matter where planted. Among double-flowered varieties, Belle of Woking, silver grey; Duchess of Edinburgh, white; and Enchantress, white, flushed with rose, are good. Single-flowered varieties are well represented by Duchess of Teck, pure white, mauve bar; Elsa Spathe, dark purple-violet; Fairy Queen, pale flesh, pink bar; Henryi, creamy-white; Marcel Moser, pale violet, red bar; Madame Van Houtte, white, suffused with mauve; Lord Neville, bright blue; languinosa, pale lavender; Sir Garnet Wolseley, blue, plum, red bar; and Nelly Moser, light mauve, with red bar.

For a south wall there is no more free-flowering subject than Solanum jasminoides, and its pure white clusters of flowers nestling among the deep green leaves, are most charming. Loniceras have much to recommend them for poles, especially L. brachypoda, sweetly perfumed, with white and red flowers; R. flava, yellow; and L. tragophylla, rich yellow.

E. Molyneux.

CHRYSANTHEMUMS.—For full instructions on the Culture of Early-flowering Chrysanthemums in beds or borders for garden or greenhouse decoration, read the Second Edition of CHRYSANTHEMUMS FOR GARDEN AND GREENHOUSE, by D. B. Crane, price 2s. 6d. net, or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

THE NATURAL IDEAL IN GARDENING.

It is ever the fashion of many writers to criticise the garden maker and his work, oft-times one meets with a criticism which borders on condemnation. The gardening community are not faultless, and many glaring mistakes have doubtless been committed by zealous enthusiasts, though frequently these same mistakes have provided the very means and knowledge to enable the gardener to rise above them.

CHRYSANTHEMUM JOSEPHINE.
A beautiful new yellow single variety. A.M., R.H.S., November 21. Messrs. W. Wells and Co., Merstham.

We are pursued by the relentless critics into many byways of horticulture, and, after various scathing indictments of garden policy, they pleasantly take us by the hand to show us how things should be done. A writer in a daily paper lays it down that the wild garden is, practically speaking, an unredeemed part of the wilderness, where exotic plants and the creations of the florist have no place. I would that my readers should ponder this carefully. Also that "the wild garden should be limited to the shrubbery belts and the woodlands adjoining the garden proper." That is, the wild, or natural, garden must bear no evidence of cultivation, or harbour any plants but natural wildings. Here let me join issue with such contentions. I am no dreamer, though my thoughts may at times range wider than the limit of the eye, but such straight-laced sentiments of garden art must militate against garden progress, unless proved to be entirely wrong.

It has been demonstrated amply that exotic subjects can be grown with English plants and trees in a perfectly natural way, in perfect harmony with an English landscape. I could name a hundred, nay, a thousand, subjects which can be harmonised with the varying features of an English landscape, which are of entirely foreign origin. The great thing for the garden maker is in the successful choice of subjects, and in this it is necessary to exercise good taste, and a thorough knowledge of plants and trees.

May I point out that delphiniums, campanulas of all types, irises, etc., are just as satisfactory in the dell as our native foxgloves. That exotic barberries, rhododendrons, and cytisus make as delightful undergrowth as English shrubs. That osmundas, onocleas, and other "foreign" ferns combine with our own athyriums, lastreas, etc., in a pleasing manner. Why, even the majority of rock gardens must be hopelessly at fault, by reason of their complement of plants from all quarters of the globe. But this is not so. Siberian plants may rub shoulders with subjects from California, New Zealanders may associate with Swiss or Pyrenean gems, Himalayan and Chinese alpines may rove among colonies of English natives, and yet not strike a jarring note or unpleasant interposition of form or colour to mar the beauty of the scene.

The whole question revolves on the suitability of the subjects used. The natural garden is to me a place where rigid lines, formal plantings, and colour designs do not exist. Where growth is only curtailed when it oppresses neighbouring subjects, and then only in as natural a manner as possible. Furthermore, the subjects must be adapted to the position and formation of the ground to be planted. I would not hesitate to plant up slopes as semi-moorlands, using Continental heaths with those indigenous to this country, Spanish brooms with mountan rhododendrons, and if need be, enlivening the scene with andromedas and pernettyas, and similar subjects, to give variety to the landscape.

Or, on the other hand, the snowy grace of philadelphuses and deutzias, the wealth of shrubby spiræas, of single and double-flowered cherries, and the beauty of pyrus and prunus, would help me fill in a background for great natural groupings of delphiniums, campanulas, foxgloves, solidagos, asters, Chrysanthemum maximum, and other plants.

It is possible to run two, or even more, styles of garden art concurrently within the confines of a single garden, if care is taken to let the lines fall naturally into each other, and to plant up adjoining ground judiciously and well. Thus the rock garden may well afford a background to the waterways, the sloping banks of the wild garden may fall naturally into a well-planted stream garden, and so on.

Again, it is also permissible to bring English wild plants into the garden proper. Campanula nobilis in variety, Lythrum roseum and its brighter forms, Linaria vulgaris, Isatis glauca, and other plants of like nature, are in keeping with the perennials of the borders, or may be used with delphiniums, starworts, senecios, moon daisies, Scabiosa caucasica, gaillardias, etc., in wild garden or shrubbery plantings, without detriment to themselves or the plants they are grouped with.

In as many ways as possible it should be the aim to be natural in planting the garden. Harmonies in forms and colourings are far better than violent contrasts. A sweep of graceful outlines, where the colour falls peacefully from shade to shade, is ever pleasing.

Contrasts are, however, of value when subtly arranged. Massive gunneras are not out of character when contrasted with tall irises or waving fronds of osmundas at the waterside. Such contrasts are ofttimes invaluable. But place an erect cypress by the side of your gunneras, or a mass of zonal pelargoniums among your irises, and the contrast is then fatal. It is just the exercise of good taste which tells. Mistakes may be remedied. But perpetually recurring mistakes of arrangement can only occur through ignorance or lack of taste, and few would accuse the present-day horticulturists of either of these faults. Garden appreciation and knowledge of plants is improving every day, and this alone will make for better and more interesting gardens.

P. S. Hayward.

EARLY-FLOWERING SUBJECTS FOR HERBACEOUS BORDER.

When planting new herbaceous borders it is desirable to include as many early-flowering subjects as may be consistent with the subsequent appearance of the arrangement, and where space is at disposal it is well to devote a border entirely to plants suitable for an early display. A border of this description should be situated in a sunny and sheltered position for preference, so as to accentuate the early flowering propensities of the plants used. Bulbs will of necessity play a prominent part in such a border, but they will be more easily planted after the other subjects are set out. Doronicum austriacum is especially showy and bright, its rich yellow blooms being freely produced, while D. caucasicum, rather shorter in growth, is equally desirable. The Globe Flowers are very effective, and succeed best in a rather moist soil; Trollius asiaticus, rich yellow; T. Fortunei fl. pl., rich gold: T. europæus, clear yellow; and T. Orange Globe, are some of the more handsome forms. The Prophet Flower, Arnebia echioides, has bright yellow flowers with brown spots, and is a gem for a border of this description. Several of the primulas are especially suitable, and should be planted in sufficient numbers to be effective, as, indeed, should all the other subjects employed. P. denticulata, bluish-lilac; P. Cashmeriana, light purple; P. japonica rosea, and P. megaseæfolia, a lovely rose coloured species, which flower early, are especially desirable.

Caltha palustris and its double form are very showy, and do well in a damp position, but are really more at home by the stream side. Some of the anemones are particularly charming, and A. apennina, with lovely sky-blue flowers, is especially so. A. pulsatilla, rich purple; A. sylvestris, pure white; and A. fulgens, brilliant scarlet, are all delightful. Double daisies are most attractive and much admired, and they can be had in various colours, including pink, white, and crimson. The gentians must not be omitted, and for this style of border Gentiana acaulis is the most suitable, as it forms handsome vigorous clumps that freely produce rich dark blue flowers. The Lenten roses deserve a place, and there are some pleasing forms of Helleborus orientalis that may be chosen, like guttatus, white, with crimson spots; lutea viridissima, greenish-yellow; and F. C. Heinmann, light purple, with dark spots. The hepaticas are attractive, early-flowering subjects, and prefer a slightly shaded position. H. angulosa has beautiful sky-blue flowers; H. triloba alba and H. triloba rubra are especially charming. Polyanthuses are very showy for early-flowering, and seedlings from a selected strain yield some very rich and varied colours. Some of the better sweet williams are worthy of inclusion, and among these Pink Beauty, Sutton's Scarlet, and Rich Crimson are highly attractive.

Violas render additional colour, and of the numerous showy varieties Councillor Waters, dark violet purple; Maggie Mott, mauve; cornuta, pale blue; gracilis, intense violet-blue, and Bullion, deep golden yellow, might be chosen. Such subjects as myosotis, double white arabis, and alyssum can be included at the discretion of the planter. Muscari conicum and its varieties alba and Heavenly Blue will be pleasing additions, the latter being especially charming. Daffodils, narcissi, tulips, hyacinths, crocuses, chionodoxas, and snowdrops will all add beauty to the arrangement. A bank of flowering shrubs would provide a glorious background for a spring border of this description, and the whole would form an object of unusual beauty.

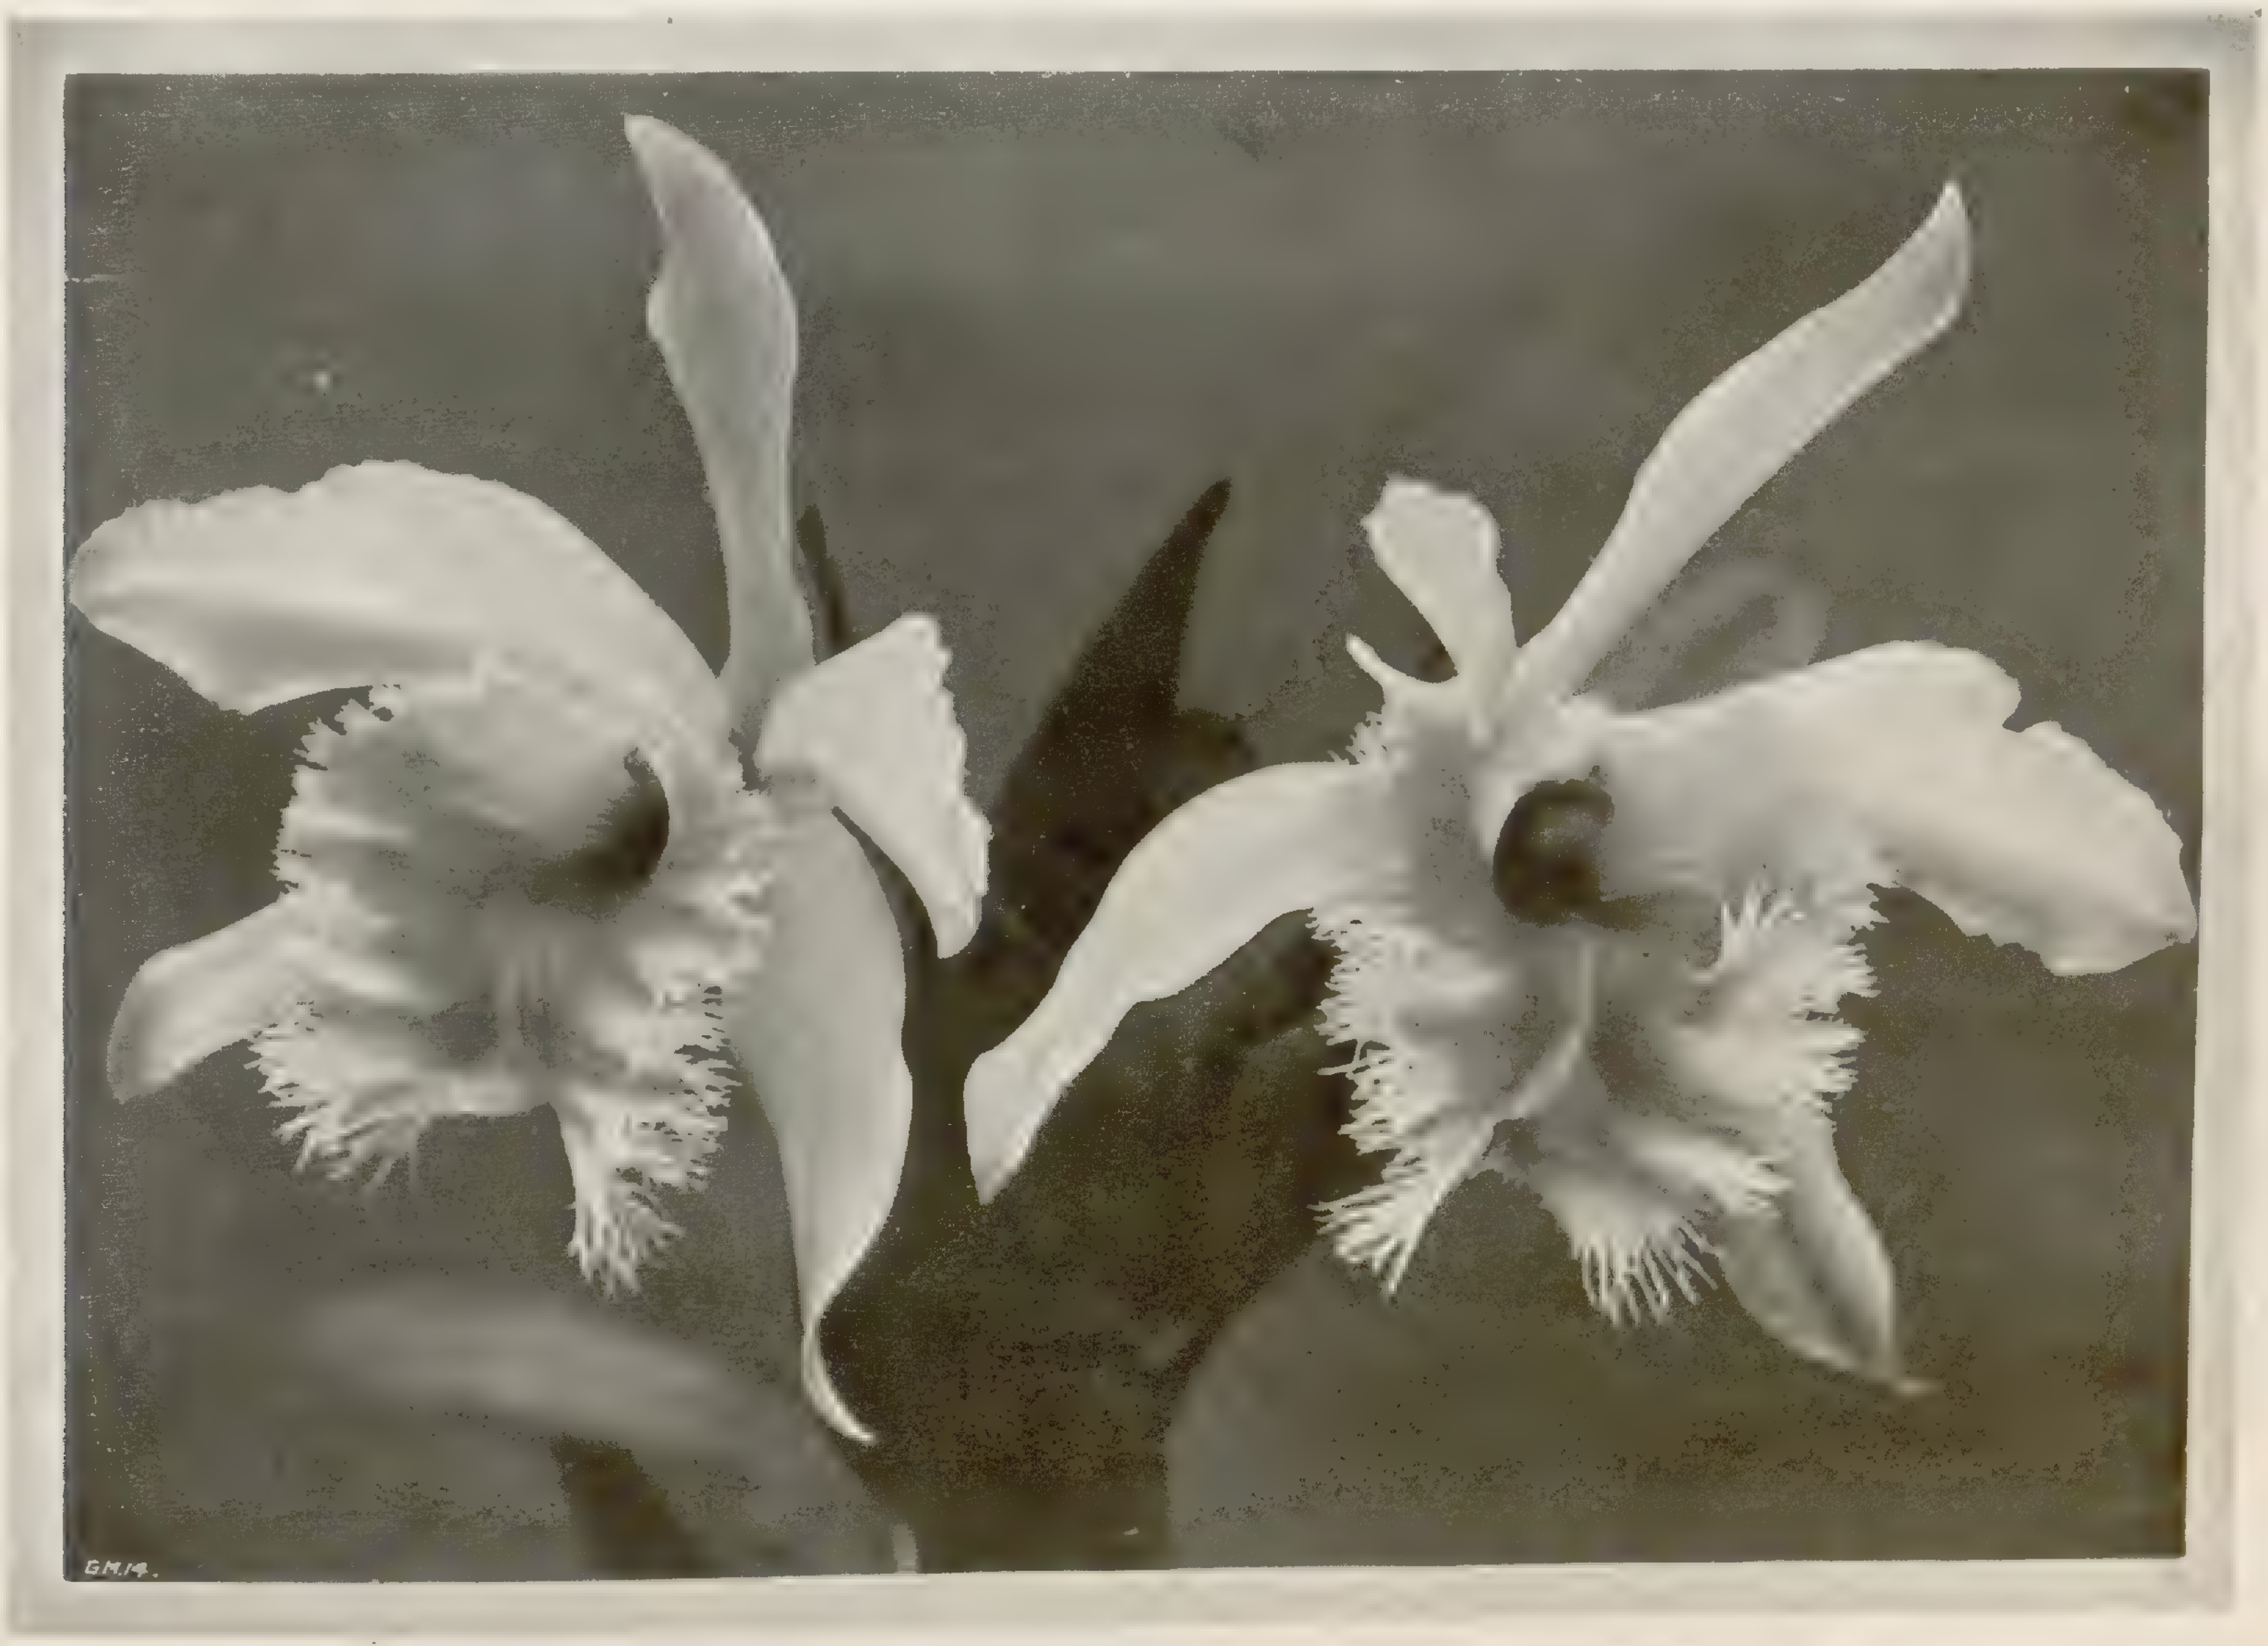
J. Gardner.

Batsford Park Gardens.

NEW PLANTS, ETC.

BRASSO-CATTLEYA DIGBYANO-MOSSIÆ HOLFORD'S VAR.

Brasso-cattleya Digbyano-Mossiæ was the first of the crosses between Brassavola and Cattleya, and it flowered at the Chelsea Nursery nearly twenty-five years ago. The hybrid is frequently known under the much better title of B.-c. Veitchi. Holford's variety is remarkable for the large size of its flowers, its white sepals and petals, and the pale greenish-yellow area at the base of the pink-tinged and beautifully-fringed lip. This variety was obtained by using the Reineckiana variety of Cattleya Mossiæ as one parent. F.C.C., R.H.S., November 21. Lieut.-Colonel Sir G. Holford, Westonbirt.



BRASSO-CATTLEYA DIGBYANO-MOSSIÆ HOLFORD'S VAR.
Flowers white, with a greenish-yellow throat to the pink-tinged lip. F.C.C., R.H.S., November 21. Lieut.-Colonel Sir G. Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester.

CYPRIPEDIUM CHAPMANI WESTONBIRT VAR.

This variety has very large flowers, and is probably the darkest and deepest-coloured form of the hybrid between C. bellatulum and C. Curtisi. The flower is heavily shaded with deep red-purple over a creamy ground. F.C.C., R.H.S., November 21. Lieut.-Colonel Sir G. Holford.

LÆLIO-CATTLEYA PRINCE OF ORANGE.

This is a further addition to the group of brightly-hued orchids that flower in autumn and winter, and for which thanks are due to the owner and grower of the Westonbirt collection. The parents of L.-c. Prince of Orange are L.-c. Hippolyta and C. Dowiana aurea. The plant is a strong grower, and, as shown, carried an erect spike of seven handsome flowers, these latter having deep and bright yellow sepals and petals, with a wavy, brilliant ruby-crimson apex to the yellow lip. F.C.C., R.H.S., November 21. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander) ,Westonbirt, Tetbury.

LÆLIO-CATTLEYA DENGANI.

A very showy hybrid from L.-c. Cappei and Cattleya Dowiana. The yellow sepals and petals are suffused with copper colour, while the large lip is vivid crimson. A.M., R.H.S., November 21. Francis Wellesley, Esq. (gardener, Mr. Hopkins), Westfield, Woking.

ODONTOGLOSSUM THAIS.

A large-flowered, strong-growing hybrid of unknown parentage. It bore a long, arching spike of broad blush-coloured flowers, heavily spotted with light rosy-purple. F.C.C., R.H.S., November 21. W. R. Lee, Esq. (gardener, Mr. Woodhouse), Plumpton Hall, Manchester.

ODONTOGLOSSUM CHIONE.

A very interesting and handsome hybrid of unknown parentage, but probably belonging to the eximium or illustre groups. It has flowers of moderate size, closely set on the spike. The sepals and petals are deep brownish-purple, with white tip and base. The spreading lip is white, with purple and gold markings, and show evidence of the plant's descent from O. Harryanum. F.C.C., R.H.S., November 21. W. R. Lee, Esq., Plumpton Hall.

CYPRIPEDIUM ELATIOR SHRUBBERY VAR.

A neat and pretty form of the hybrid between C. Leeanum and C. Baron Schröder. The white, flattish dorsal sepal is brightly marked with purple, while petals and lip are bright brown and purple. A.M., R.H.S., November 21. F. M. Ogilvie, Esq. (gardener, Mr. Balmforth), The Shrubbery, Oxford.

BRASSO-CATTLEYA LEUCOTHŒA.

A small but pretty hybrid from Brassavola nodosa and Cattleya Schröderæ. The flowers are of medium size and pure white, save for a yellow mark in the throat. A.M., R.H.S., November 21. Messrs. J. and A. McBean, Cooksbridge, Sussex.

LÆLIO-CATTLEYA W. J. BIGGS.

An attractive hybrid of unknown parentage; the sepal and petals are tawny-yellow, and the lip dark purple. A.M., R.H.S., November 21. Mr. W. J. Biggs, Browning Road, Enfield.

CÆSALPINIA PULCHERRIMA.

An old but rarely-seen plant, and one that needs considerable space in a stove house. The large pinnate leaves are elegant, and the big clusters of bright orange-red flowers are very attractive. C. pulcherrima, also known as Poinciana pulcherrima, is a native of the West Indies. A.M., R.H.S., November 21. Mr. G. Evans, Baldock.

CÆSALPINIA PULCHERRIMA.

Godfrey's Perfection.—A beautiful free-flowering anemone variety that opens creamy white, but quickly becomes pure white. This is a particularly fine decorative chrysanthemum either disbudded or grown to produce sprays. A.M., R.H.S., November 21. Mr. W. J. Godfrey, Exmouth.

Mrs. Walter Hemus.—A large and graceful single variety, ruby-crimson, with a yellow disc. A.M., R.H.S., November 21. Mr. W. H. Page, Tangley Nursery, Hampton.

Thomas Page. — A reflexing Japanese variety of decorative size and value; it has bright mauve-pink florets, and is very attractive. A.M., R.H.S., November 21. Mr. W. H. Page, Hampton.

Josephine.—A very fine single variety with more than one row of florets; these latter are broad, and neatly arranged to form a showy substantial bloom. The colour is clear yellow. A.M., R.H.S., November 21. Messrs. W. Wells and Co., Merstham.

Marjorie Lloyd.—A pretty single variety, the colour being soft apricot-orange. A.M., R.H.S., November 21. Messrs. W. Wells and Co., Merstham.

Merstham Gem.—An orange-coloured single variety with a yellow zone round the disc. A.M., R.H.S., November 21. Messrs. W. Wells and Co., Merstham.

Miss Margaret Gray.—A big single variety, bright tawny yellow, with a pretty flushing of rosy-pink. A.M., R.H.S., November 21. Mr. P. Ladds, Swanley.

Miss Phyllis Bryant.—Another large single variety that might well be called a Japanese single, seeing that the florets droop gracefully at the tips. The colour is soft yellow. A.M. R.H.S., November 21. Mr. P. Ladds, Swanley.

Primrose Girl. A useful decorative single variety, producing large elegant flowers of a very attractive shade of bright yellow. A.M., R.H.S., November 21. Messrs. James Veitch and Sons, Chelsea.

Norbury Yellow.—A medium-sized decorative variety of very rich bright yellow colour. A.M., R.H.S., November 21. Mr. George Kent, Norbury.

Yellow Cap.—This fine yellow form of the old Caprice du Printemps was described in our issue of November 25, p. 878; and reference to the splendidly decorative bush plants of this variety, grown and exhibited by Messrs. James Veitch and Sons, Chelsea, was made in our issue of November 11, p. 833. We now have pleasure in illustrating a fine specimen of this variety as grown and exhibited by the Chelsea firm.

BEGONIA FASCINATOR.

Next to B. Mrs. Heal, this new comer must be accounted the finest of the series of winter-flowering begonias raised at Chelsea. It is a most attractive variety, flowering freely and bearing large orange-buff, or salmon-orange coloured flowers. The colouring is quite distinct in this section of begonias, and should materially help to popularise these winter bloomers. A.M., R.H.S., November 21. Messrs. James Veitch and Sons, Chelsea.

PLUM PRESIDENT.

A large late culinary variety; deep purple with a blue bloom on the fruits. The fruits illustrated were grown by Mr. W. Messenger, Woolverstone Park Gardens, Ipswich.

PLUM PRESIDENT.

Plums are so numerous and the majority are so useful that to emphasise the good qualities of any one would seem to imply that it was quite superior to all others. But this is not necessarily the case, because plums ripen over a fairly long period, and are by no means the short season crop that the market or the greengrocer's shop often suggests. In the case of culinary plums, that is, those which are not useful at any time for dessert purposes, there are some ready for use in July, like Early Rivers, while others are at their best in October. These quite late plums are most valuable in private gardens, where a regular supply over a long period is needed, and one of the best is President, raised by Messrs. T. Rivers and Son, of Sawbridgeworth. This variety has large oval fruits of deep purple colour, thickly overlaid with blue bloom; it is a free stone variety, rich and sweet in flavour, and it is a very free bearer. The dish of fruits illustrated represents one exhibited at Westminster at the Royal Horticultural Society's Fruit Show, a few weeks ago, by Mr. W. Messenger, gardener to C. H. Berners, Esq., Woolverstone Park, Ipswich. Readers of the Gardeners' Magazine will remember that Mr. Messenger, and Mr J. Vert, of Audley End Gardens, Saffron Walden, are two of the most successful growers and exhibitors of plums nowadays.

Roses.—It is rather early to refer to the planting of roses, but it is advisable to suggest that the time has arrived for preparing the soil, so that all will be in readiness when the time arrives. The preparation of the beds is an important point in the successful cultivation of roses, and there should be no hesitation in carrying out the work in a thorough manner. Undoubtedly a good stiff loam is the most suitable, but almost any soil may be worked into such a condition that will adapt it to the requirements of roses. For instance, if the natural soil is light and poor, a liberal quantity of heavy loam should be thoroughly worked in with it when trenching. If the bottom spit is stony remove it altogether. Add also a small quantity of well-decayed cow manure. Where the soil is a strong wet clay, remove it, and place drainage in the bottom of the bed to prevent it becoming sour through stagnant moisture. Heavy soils will be improved by adding a liberal quantity of sharp road grit and a little wood ashes.—E. C. Pooley.

ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.

The following is the text of the paper read at the meeting of the Royal Horticultural Society, on November 21, by Mr. Edward White, hon. managing director:

The council of this society has courteously placed the lecture hall this afternoon at the disposition of the directors of the Royal International Horticultural Exhibition, and so enabled them to call attention to the great event of next year. Perhaps one may go so far as to call it the great horticultural event of this generation.

Many of the flower shows held throughout the country have developed into important affairs, but not one has approached, in the British Isles, the great International Horticultural Exhibition of 1866. Although at first sight it seems surprising that no attempt has been made to repeat the great success of that show, those who have taken a part, however modest, in the organisation of such an event can appreciate tolerably well the reason for such a long interval,

International Horticultural Exhibitions Abroad.

There have, moreover, been some special international displays during recent years at Paris, Ghent, Berlin, Haarlem, Florence, Lyons, Turin, and elsewhere, and one will also take place in Russia in 1913.

Naturally each of these important affairs has presented some separate and valuable lessons in horticulture, and English visitors have quitted them with a persistent feeling that the time has arrived for British gardeners once more to assert their supremacy, and show the world the utmost of which they are capable.

The Flemish town of Ghent claims an important place in the history of horticultural exhibitions. It is there that the Royal Society of Agriculture and Botany holds every five years great shows, which date back intermittently for some 300 years. Visitors to the last show, held in 1908, will remember particularly the magnificent display of azaleas, camellias, and orchids, and the charmingly artistic effect of the arrangement of the exhibition with roomy walks and panoramic backgrounds. It may be claimed that English exhibitions scored a great triumph in the orchid class by the marvellous display made by Sir George Holford.

The relations between leading French and English horticulturists are of a very happy nature, and many of the latter make a point of attending the periodical shows at Paris, which always add to one's admiration for the artistic and decorative ability of our neighbours.

The completeness of the Berlin Exhibition in 1909, which was held as early as April, was a revelation to English visitors. The show of fruit for such a time of the year was surprisingly good.

A wonderful show of tulips was seen at last year's Jubilee Exhibition at Haarlem, where the great bulb gardens, for which the town is famous, were to be seen in masses, displaying a galaxy of beauty in form and colour.

The Chief Characteristic of the International.

The chief characteristic of our own exhibition of 1912, at the end of May, will probably be the all-round quality of the exhibits rather than the supremacy of any one class, except perhaps orchids. Some few objections, by the way, may be raised to the date of the show, but these would be possible whatever season was fixed, and the days decided upon after the most careful consideration by the directors are undoubtedly the most convenient generally, and offer the best all-round opportunities for the display of British horticulture in all its branches. It has also been proved by experience on many occasions that the public are more eager to attend spring shows than those held later in the summer.

The dear old phrase, "horticulture in all its branches," falls very easily from one's lips. This is not to be wondered at, considering the amount of oratory for which it has been responsible since the days of Gerard and Parkinson. It would be useful sometimes to consider what it really means, instead of using it in the automatic fashion to which we have become accustomed. As the exhibition is designed to serve horticulture in all its branches, it will be legitimate to give a moment's consideration to some of the branches, and see how broadly they spread.

Many of us are too busy clinging to our own particular limb to realise of what a giant tree it forms part, and the great economic importance of that tree in our country.

Economic Importance of Horticulture.

We ought to be in an exceptional position to appreciate these facts when we have before us the statistics of the census of production with regard to the horticultural industry which will very shortly be published, and should be well worth the study of all who are interested in the progress of the art.

Taking first that branch of chief interest to the members of this society, we should look for particulars of the great nursery, florist, bulb, and seed trades; incidentally we might hope to learn the extent of the acreage of the most highly or intensively-cultivated land to be found in the country, and we might estimate roughly therefrom the number of employés occupied and maintained in the handling of these great industries.

Well organised though they may be, thanks in a great measure to the Royal Horticultural Society, these trades represent in volume, however, but a small proportion of the horticultural industry in full, or even of that part concerned with the management of gardens.

To realise this, we need only picture the comparatively few gardens we know personally, and think of the quantity and value of the other materials used in their construction and maintenance, the architectural features and adornments in conservatories, horticultural buildings, garden ornaments, fencing and gates, the varied machinery, implements, tools, manures, fertilisers, and all other details which represent some branch or other of the craft.

Among other points of information we might glean some idea of the number of owners of private gardens of a considerable area and how many million acres of land in this country are devoted altogether to gardens and parks, both public and private, or the area of glass-covered land now existing in the country with that of fruit and market gardens.

In these days of small holdings, innumerable market gardens, and fruit farms, it is difficult to say exactly where horticulture begins and agriculture ends, and it is not unlikely that the latter industry will be credited in the census returns with a large share of these, the most extended branches of the tree of horticulture. This point will be noted by those anxious to assert on behalf of the art all the importance that rightly belongs to it.

The Place of Exhibition and General Arrangements.

One of the greatest assets that horticulture possesses is the uncreasing sympathy shown by the Royal Family in its welfare. This sympathy is reciprocal, and the pleasure with which the directors received King George's gracious promise to open the exhibition on May 22 next, at twelve o'clock, will be shared by all who are interested in the success of the exhibition.

The considerable difficulty in securing a suitable site was eventually overcome by an arrangement to occupy twenty-one acres of the grounds of the Royal Hospital at Chelsea, which include the Ranelagh Gardens. The position is ideal in many respects, among its advantages being two ample entrances from Queen's Road and the Chelsea Embankment respectively, within a few minutes' walk from Sloane Square station. There is open space for tents covering nearly five acres, and there are, in addition, several broad, shaded avenues, and the sheltered and mature gardens, which offer a good sample of Middle Victorian landscape gardening, and will make a perfect background for outdoor exhibits and the rock and water gardens, which are expected to be of particular interest.

It is proposed to illuminate the grounds and engage the best military bands available, so that, given fine weather, a series of delightful floral fêtes will be feasible. A provisional plan of arrangement has been issued, and it is the determination of the directors that there shall be no avoidable cause of complaint in the matter of ventilation and space in the gangways. In this respect I may mention that the largest tent, which will cover nearly three and a-half acres, is divided into five spans, 45ft. in height, with special ventilation for the whole length of each ridge, the total length of the tent being about 220 yards. The gangways are from 15 ft. to 20ft. wide. The show space in this tent amounts to nearly 75,000 square feet, and will provide, if necessary, table run of nearly half a mile.

It is necessary to state that the tenancy of the premises will be too short to enable the production of an artistic scheme to compete on equal terms with the permanent sites of some Continental exhibitions, but at salient points striking effects will be produced from views of the great expanse of flowers, and the general arrangements will be much less complicated than are usually found at such exhibitions. It may be mentioned that the 1866 exhibition was held on the site now occupied by the Natural History Museum at South Kensington, adjoining the then existing premises of the Royal Horticultural Society.

Financial Aspects.

Experience has proved — fortunately in realms other than of horticulture—the folly of entering upon such an enterprise without ample financial guarantees. We are happy to state that the support already accorded, both in the matter of guarantees and subscriptions, has been more than encouraging, so that with a continuation of existing experiences the anxiety of the directors with regard to finances should be reduced to vanishing point. This is not to say that guarantees and subscriptions are no longer earnestly invited. They are still wanted, and may be confidently expected in view of the substantial privileges which are offered in return. A subscriber is in effect the prudent person who buys a ticket or tickets beforehand at a cheap rate, and at the same time is entitled to the happy feeling that he is becoming the patron of a most worthy cause. This would, of course, be an ungracious way of describing the liberality of many donations, among which may be mentioned that of your own great society to the amount of £1,000, with a further guarantee of £4,000. From all appearances there is little need to worry about the guarantee.

It is worth noting that £1,000 represents the contribution of a trifle over 1s. for each guinea member of the society. In return for this the reductions of the charges to Fellows are about 25 per cent. on the first day, which may be looked upon partly as a subscriber's day, and of 50 per cent. on all days other than the 1s. days; so that the Fellows may congratulate their council on having achieved another of those strokes of business which do so much to popularise their Society.

The published lists respectively of guarantees and subscriptions are £4,000 and £16,000.

The directors have recognised the desirability of encouraging the attendance of professional gardeners, and have therefore reduced the charges of entry very considerably to this class of visitor.

The directors have been assisted immensely in all of their work of organisation by the systematically kept records of the 1866 exhibition, and the balance-sheet has also been a continual source of reference. We find that the expenses of this exhibition amounted to something over £12,000, the final profit being about £3,500. This substantial sum was exhausted in making a donation to the Gardeners' Royal Benevolent Institution and in the purchase of the valuable Lindley library, which is such a cherished possession of the Royal Horticultural Society. Needless to say, the expenses of 1912 must be considerably greater. Putting aside other considerations, this would be easily understood in examining the respective schedules for 1866 and 1912.

Schedule of Prizes.

In order that I might have an authoritative statement on this subject, I asked Mr. Harry J. Veitch (who, as is well known, is the only surviving member of the committee of the 1866 exhibition) to be so kind as to supply me with a few notes in his capacity of chairman of the Schedule Committee for 1912. Mr. Veitch says it is not easy to compare the two schedules. There were 220 classes in 1866, as against 428 in 1912. Exhibitions in groups as such were practically unknown in 1866, all classes specified the number of plants to be staged.

For 1912 the applications for spaces for groups already number no less than 100.

In 1866 the largest class for stove and greenhouse plants comprised 16 plants. This is in striking contrast to the requirements for next year.

The orchid classes have grown from nine in 1866, the largest class being 50 plants, to 29 classes, with two groups of 500 square feet.

The prizes offered for roses tell the tale of the development of that favourite flower, for besides the novelty classes, there are 26 classes, as against 8 in 1866. In the last exhibition the largest class was for 20 roses in pots 8in. across. In 1912 prizes are offered for groups not exceeding 500 square feet. We have nine classes of cut roses, against one class in 1866; and so on throughout the schedule.

These figures tell in tabloid form of the development of horticulture since 1866, and of the advance particularly in the specialisation, which is such a great feature to-day.

It may be noted that rock and water gardens were not seen in 1866, nor many of the handsome florists' flowers as we know them to-day.

While on this subject we may mention that applications for space for collective exhibits have come in from several foreign countries, as well as from individual counties in Great Britain, and that the entries already exceed 400, irrespective of the exhibition of horticultural sundries. This section promises to be the most complete and interesting that has as yet been seen.

It is not incumbent upon me to give particulars of the exhibits entered, but I am at liberty to mention for one thing that a commission has been given by an American gentleman for a very remarkable piece of garden statuary on the express condition that it is shown at the exhibition.

It may be mentioned that no special prizes were offered in 1866, whereas already no less than 38 very fine cups and awards have been promised, in addition to the special cups given by many counties. It will not be invidious to inform Fellows of your Society that, in addition to the cup graciously promised by the King, and the one offered by the president of the exhibition, the Duke of Portland, others are being given by Sir Trevor Lawrence, Sir George Holford, Sir Jeremiah Colman, and Mr. Gurney Fowler, the last-named gentlemen being respectively the treasurer and chairman of the exhibition. The total prize list will probably exceed £4,000.

Horticultural Education and Science.

There are many more matters of interest to which there is no time to refer, but the work of the Science and Education Committee should be mentioned, because it is hoped that this will be one of the most efficient and permanently valuable features of the exhibition. It is only necessary to point out that the president of the committee is the Right Hon. A. H. Dyke-Acland, P.C., who is throwing the greatest energy into the work, and that the secretary is Mr. F. J. Chittenden. A glance through the list of distinguished men forming the committee will complete the feeling of assurance upon the question of the efficient work to be expected.

Their labours are divided into two parts, one dealing with horticultural education and the other with the scientific side of horticulture.

There will be no exhibits in connection with education, but a special building has been allotted to the scientific exhibts, and will contain some highly interesting specimens under the following sections:—

(1) Vegetable physiology.
(2) Genetics.
(3) Economic entomology.
(4) Economic mycology.

Several very valuable and interesting exhibits have been promised by gentlemen, to whom horticulturists have every reason to be grateful. It may be added that many of the leading investigators on the Continent and in America have also promised their assistance.

All scientific exhibits will have a bearing on practical horticulture, so that this department of the exhibition will be of popular interest, and not merely a happy hunting-ground for the scientic student or a place of refuge for those who are seeking a quiet part of the exhibition.

The conference, which will be held in the fine recreation hall at the hospital, will be devoted to two subjects only, since it has been determined by the committee, wisely, it will probably be agreed, that it is much better to thoroughly thrash out two subjects only than to rush frantically through hosts of lectures, which no one has time to listen to, much more criticise.

I may mention that there were something like forty or fifty papers presented at the congress of 1866 dealing with subjects, many trivial and uninteresting.

The first subject for consideration will be the broad question of horticultural education. In preparation for this discussion, the committee is making thorough inquiry into the system of education in horticulture in this country and the public and private facilities which are open to students.

It is hoped that an exhaustive report will be completed and ready for placing in the hands of those who attend the conference to serve as a basis for discussion. Many prominent educationists from the Continent and America have undertaken to assist in the discussion or to read papers dealing with special points on horticultural education in their own countries.

The second part of the conference will deal generally with legislation in connection with plant diseases. Information on this important subject is being obtained both in this country and abroad, and will serve as a basis for a report to be presented to the conference on lines similar to those proposed in connection with education. Many prominent people in this country and from abroad have undertaken to participate; and the Board of Agriculture have promised maps, showing the progress and distribution of certain plant diseases and pests which it has been deemed advisable to legislate against.

Social Functions.

One of the most pleasant, and at the same time the most onerous, duties in connection with the exhibition will be the entertainment of the many distinguished foreign guests who will undoubtedly visit this country next May. The reception committee is under the chairmanship of Sir Albert Rollit, and a programme is being drawn up for the entertainment of our visitors, which is being simplified by the hospitality already promised from private and other sources. The president of the exhibition, the Duke of Portland, has generously offered to hold a reception at his town house. Permission has been graciously given for a visit to the Royal Gardens at Windsor. The distinguished president of your society in his private capacity and Mr. Leopold de Rothschild, The Royal Horticultural Society and others have also intimated their hospitable intentions. If the history of 1866 were to repeat itself, there would be a great banquet at the Guildhall. There should be little fear that the British gardeners who have visited foreign exhibitions and enjoyed the hospitality offered them will feel any shame at the way their former hosts are treated on their arrival in this country.

Continental Opinions.

I cannot do better than conclude my remarks by quoting, by permission, some opinions with which I have been favoured by one or two foreign gentlemen intimately connected with the management of their own international horticultural exhibition.

Herr Siegfried Braun, the secretary of the Berlin Exhibition in 1909, writes:—

> Much could be said in a general way on this subject, but if you wish to know what tangible advantages for the horticultural industry of my country resulted from the International Horticultural Exhibition of 1909, I personally believe that one cannot value them too highly.
>
> An exhibition, such as the one which took place in Berlin, affords to the experts in their many-sided interests lasting inducements to further efforts. It shows clearly what has already been achieved, and what there is still to learn. This knowledge is in itself a powerful lever to progress in any profession. Besides, such an exhibition stirs up the gardening enthusiasm of both professionals and amateurs, and induces them to spend more money on plants and flowers, thus conferring an added blessing on the industry
>
> It is as instructive as it is interesting to follow up how far these results sometimes reach in isolated cases.
>
> I trust that your proposed exhibition for the year 1912 may be the means of bringing tangible profits to your country.

Monsieur Abel Chatenay, the capable general secretary of the French Agricultural and Horticultural Committee, says:—

> I have had the opportunity of noting personally how far International Exhibitions have had influence in business relations between the countries taking part. The small number of your English colleagues who have taken part in our exhibitions could testify sufficiently as to the results obtained by the growers of sweet peas and carnations and a few other specialities, by virtue of the excellence of their product, and through their exhibits, have obtained numerous orders from the Parisian public.
>
> I consider from another point of view that it is beneficial for horticulturists of various countries to be able to get into touch with their colleagues. It is impossible for questions of general interest to be limited by geographical frontiers, and professionals from the various countries should be able to exchange their views from time to time. It is only in a large exhibition where they can meet and know one another, either as jurors or as exhibitors. The interchange of ideas is of great interest to all.
>
> From this point of view Belgian horticulturists, who are excellent exporters, have realised fully the utility of such manifestations, of which their quinquennial show at Gand is a good example.

The present secretary of the Ghent Society, to which I have so frequently referred, is Monsieur Albert Ceuterick, and he has favoured me with the following views:—

> One cannot fully define the immediate effects of our exhibition on the horticulture of Belgium, but our society, which for a century has not relaxed its efforts to develop and improve these demonstrations of the horticulture industry, is convinced that the result is incalculable profit to the producers.
>
> With this view our society and our horticulturists impose heavy sacrifices upon themselves to make them succeed.
>
> Horticulture is a subject specially appropriate for exhibitions, but these exhibitions by their importance and their fame attract to Ghent the chief botanists, the amateur and professional gardeners of Europe. Some come as judges, others to satisfy their curiosity, and to follow the progress of horticulture.
>
> Existing commercial relations are confirmed, and new connections are created. Firms which exhibit make the acquaintance of numerous foreigners and widen their outlook.
>
> In one word, it is an advertisement of extraordinary importance, and it is not necessary nowadays, to insist upon the value and advantage of advertisements, although its effects are not immediately apparent. Nevertheless, it is our profound conviction that the development and prosperity of our horticulture are intimately bound up with our quinquennial exhibitions.
>
> You are good enough to suggest that my efforts had something to do with the success of the exhibition in 1908. May I say that the success of all of our exhibitions of which our society is very proud is to be attributed not to the individual efforts of one member or another, but in the perfect union which has existed from time immemorial, first between all the members of the committee, and then between the committee and all the horticulturists in our country.

These last words of Monsieur Ceuterick deserves letters of gold, and present an ideal worthy of emulation by everyone connected with the Royal International Horticultural Exhibition.

It would be premature to boast, but there is every reason to believe that when the history of the great enterprise of 1912 is recorded, an epitaph equally creditable to British horticulture may be inscribed.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

THE COOL HOUSE.—Many plants will now be found with their flower scapes in different stages of development, and the bulk are just completing the growth of the new pseudo-bulb. It is just at this latter stage that the flower scapes make their appearance, and careful observation is necessary to protect the spike in its early development against the attacks of slugs and shell snails. A piece of cotton-wool carefully wrapped around the base of the leaves, with the woolly side outwards, provides a barrier over which these pests have a difficulty in passing. Some pieces of lettuce leaves placed on the surface of the potting compost, and about the stages, or some bran or brewer's grains put on pieces of crocks, will provide traps, and, with the aid of a light during the evenings and early morning, the slugs will be found feeding, and are easily caught and destroyed. The protection of the flower scapes is by no means a light matter, for when we consider that the labour and care of a whole year's work may be destroyed in a single night by either of these pests, the time occupied in protection must be given.

RESTING.—If there is any period when the odontoglossums may be given a little rest it is just at that period when the growths are completed. Care should be observed not to overwater. See that the potting compost becomes dry between waterings. No hard and fast rule can be laid down as to how often plants require to be watered; the situations and conditions under which cool house orchids are cultivated are so exceedingly variable, that the quantity of water the plants may require, both at the roots and in the atmosphere, must be entirely governed by these conditions. In the treatment of the cool house orchids, one cannot avoid contrasting the successful treatment given now with the conditions that were considered necessary some twenty years ago. It was no uncommon thing to advocate a temperature of 40 to 45 degrees as suitable in the winter for odontoglossums and other cool house orchids. The result was that the plants presented a stunted appearance, and there was little, if any, advance in the size of the pseudo-bulbs from one year to another. There are few successful odontoglossum growers to-day who do not advocate ten degrees higher temperature for the winter than those mentioned above. After all, this is only reasonable, when we take into consideration that the most active season of growth for the bulk of the plants, and the strain of flowering, is from the month of September until the end of April. It is right, therefore, that we should afford the plants grown under artificial conditions that which Nature always provides at the time when every encouragement is necessary to meet their requirements. Where this is realised, and I believe it is generally so now, very little difficulty is experienced in growing the plants; or, where hybridisation is practiced, in successfully raising and developing the seedlings.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CHRYSANTHEMUMS.—Particular notice should be taken of the different varieties while they are in flower, so that none but the best shall be grown another season. Discarded varieties should be thrown out as soon as the flowering period is over, and those to be retained should be encouraged to make strong, sturdy cuttings by placing them in a position near the glass, where they will receive plenty of light and air. Thin out any weakly cuttings which have already shown themselves, to enable the remainder to become strong. Any varieties that are shy in producing cuttings will be the better for a top-dressing of fresh material to encourage new root action. A few cuttings may now be inserted to make large specimen plants.

PELARGONIUMS.—The zonal varieties are now making a fine show, and careful watering is necessary, especially in dull weather. Fog is very destructive to the beauty of the flowers, and must be excluded from the house in which they are growing. When cut, the flowers will last much longer if a little florists' gum is dropped into the centre of each bloom. The show varieties, which were cut back some time ago, are making good growth, and will require potting. The potting compost calls for care in its preparation. Too often the grower errs in adding a quantity of manure, which only tends to the production of long, sappy growth, which is practically useless for flowering purposes. Good turfy loam, with a little leaf-soil and sharp sand, forms an excellent material for pelargoniums, and, if potted firmly, strong, short-jointed growth will result. About a fortnight after potting, the points of the growths may be pinched out to make the plants branch.

CINERARIAS AND CALCEOLARIAS.—The plants still in frames must be encouraged by supplying an abundance of ventilation whenever the weather permits. Keep them close to the glass by standing them on inverted pots. An application of manure at intervals will greatly benefit them, diluted cow manure suiting each kind admirably; but care must be taken that it does not touch the foliage. It is necessary to fumigate periodically to keep greenfly in check. Take the precaution of having plenty of material handy for protection from frost.

SCHIZANTHUSES.—The several batches of schizanthuses must be kept continually growing; if they are allowed to become root-bound, premature flowering will be the result, and this renders the plants practically useless. Artificial heat is only necessary in very severe weather. Overwatering and excessive heat account for more failures with these useful plants than any other causes.

BULBS.—Relays of bulbs, etc., should be brought into gentle heat at regular intervals to maintain the supply of flowers for decoration.—A. GRUBB, Porters Park Gardens.

HARDY FRUITS.

PEARS.—The free-flowering habit of some pears in certain seasons must of necessity absorb a great deal of vitality, and no doubt if the latter could be preserved the trees would be more capable of setting and ripening a crop of fruit than would otherwise be the case. There is such an abundant show of blossom buds on pears this year that the present favourable occasion should be taken advantage of to put all old trees in order. This may be done by shortening each spur growth to two or three fruit buds, and other growths that have been regularly stopped throughout the summer may be shortened with a view of producing fruit spurs for the following season. When pruning pears it will be found necessary to give more freedom to some varieties to get them to fruit successfully than is necessary with others. Beurre Giffard, Jargonelle, and Durondeau, for instance, will produce most of their fruits on wood of the previous year's growth that is several inches long.

YOUNG PEAR TREES.—Young cordon trees should need but little winter pruning if the summer stopping has been fully carried out. Encourage the trees to furnish their allotted space as soon as possible. If they are healthy and strong, they may have the leads cut back to two or three eyes to ensure a stronger lead next year; those that are stunted through overcropping may also be severely pruned to encourage new growth. Horizontally-trained trees will need to have their leaders shortened back to where the next pair of branches is wanted, taking care that the buds are pointing in the direction required; the regulation of these trees is best carried out during the summer, by stopping, the aim being to keep all leads of equal strength.

PLUMS ON WALLS.—Provision should be made during the summer for laying in young growth for refurnishing plum trees that may be getting old. By this means trees may be renovated and brought to a more fruitful state. This young wood, being an outlet for the energy of the trees, will usually bear more and finer fruit than the older spur growth, and should thus be encouraged where possible. Allow plenty of space when nailing, so that all light possible may penetrate to thoroughly ripen the wood.

FIG TREES.—Fig trees, in all except the most favourable positions, will now need some protection to ward off severe frost, because, in very hard weather, the embryo fruits are likel yto be damaged, and next year's crop cnsequently lost. If the trees are tied loosely in bundles and enveloped in archangel mats, this will usually be found sufficient protection during the most severe winter.—J. WHITTLE, Cheveney Gardens.

THE KITCHEN GARDEN.

EARLY CARROTS.—Young roots are always in demand in large private establishments; to secure the first crop a beginning should be made by making up a hotbed with sweetened manure and leaves, making the whole thoroughly firm by treading. A heated pit is very handy for the first sowing or two, as during severe weather the frost can be kept out and the crop more easily managed. Failing this the ordinary wooden frame with good waterproof lights will meet the case, but much time is often taken up with necessary coverings as well as lining the hotbed, to keep up the required heat. Use sweet rich, sandy soil, about nine inches in depth, and when the young plants are up admit air to them whenever the weather will allow, avoiding cold cutting winds. A variety of French Short Horn is the most suitable for the sowing.

TOMATOES.—If a sowing of seed is made early this month it will supply plants to come into bearing after the winter ones have completed their crop. Sow the seeds in small pots filled with sweet open soil. Grow the plants near the roof glass in a temperature of about 60 degrees. As they develop put them into slightly larger pots. I find Sunrise is a reliable and satisfactory variety in every way for early fruiting, especially for pot culture.

LETTUCE.—Where there is a shortage of lettuce plants, owing to the seed not germinating properly, make a sowing now in boxes or pans. Grow the plants sturdily in a light position in a greenhouse until large enough for pricking off. If planted out over a mild hotbed in wooden frames, at about six inches apart, and liberally attended to, they will soon grow into useful material. All the Year Round is one of the varieties that readily yield to this mode of culture.

RHUBARB.—A successional and larger quantity of crowns should be lifted now, and exposed for a week or so; afterwards, if planted in the mushroom house or a warm situation in a hot-house, they will give produce in quantity when apples are getting scarcer. Water the crowns with warm water, and keep a moist atmosphere by syringing their surroundings. In small gardens, where proper appliances do not exist for forcing this vegetable, old crates or tubs may be placed over the crowns and warm manure and leaves mixed can be arranged round them to give off a mild heat. Produce from this kind of forcing is often tainted in flavour. Therefore it is necessary to allow a little air to reach the young growths when the weather is suitable, to permit of the escape of ammonia.

GENERAL REMARKS.—Owing to the clearance of autumn cauliflowers and some other crops from the larger quarters of the garden, manuring, trenching, and digging should be actively carried on. Select some strong tubers of early potatoes and place them in boxes, in a light position in preparation for the first plantation in pots or pits. Remove all growths but two of the strongest on each set. Frequently examine and pick over the stock of endive and lettuce that are planted in frames, to prevent damping and decay from spreading as much as possible.—C. FLACK, Cholmondely Castle Gardens.

EXHIBITIONS AND MEETINGS.

Northern Fruit Congress.

A lengthy programme was arranged in connection with the Newcastle Flower and Fruit Show, on Wednesday and Thursday, November 15 and 16, by the North of England Horticultural Society, and those who were associated with the Rev. Bernard Hall, at the Hexham Congress in 1910.

On the first day the meetings were held in the Mining Institute, Newcastle, a short distance from the Town Hall where the show was held, and the meetings suffered as a consequence. Although one might have expected the Congress to deal only with fruit culture and relative subjects, the lectures extended from these to horticultural education, soil bacteria, and soil sterilisation, and even to early-flowering chrysanthemums.

On the second day the attendance was so small on the occasion of Mr. Chisholm's demonstration and lecture on fruit bottling, an effort was made to secure a room at the Town Hall for Mr. Little's demonstration on pruning. This was successful, and the rather small room secured was crowded out. The last session, held Thursday evening, was for the best in point of comfort and attendance, as it was held in the splendid Council Chamber at the Town Hall.

FRUIT CULTURE IN THE NORTH.

The first session was presided over by Captain Cuthbert, D.S.O. It was held in the Mining Institute, some little distance from the Town Hall, and, including Press men, there were thirty-seven persons present.

Mr. J. S. Chisholm, Horticultural Instructor to the Northumberland County Council, in his opening remarks, referred to the importation of 3,242,582 cwts. of apples in 1910, to the value of £2,189,309, while the imports of fresh fruits of all kinds reached the total value of £10,606,906. This, he said, suggested a big standing order for fresh fruits, and opened up the questions of fruit culture, available land, and facilities for marketing. There was a movement in the right direction, but even now Herefordshire had only 6 per cent. of her land under fruit culture, and Kent a little more, while in Northumberland there were only 284 acres of orchards and 268 acres of small fruits; Durham had 227 and 301 acres respectively; and Westmoreland 407 and 52 acres.

This restriction of area was due chiefly to climate, but also to limited markets and difficulty of securing good land for fruit culture. It has been proved, however, in spite of difficulties, that good crops of fine hardy fruit can be grown in the four northern counties, and he believed the business could be made an increasing and a profitable one. At present in many orchards there were too many varieties, and the fruits of inferior quality, consequently it was not surprising that such fruits did not find a ready market. Mr. Chisholm advocated the selection of suitable varieties, dwarf trees, the right stocks, and early fruiting varieties. He objected to young, frequently transplanted trees, covered with fruit spurs, for planting purposes, and advocated young trees in full vigorous growth.

The markets, he said, must determine the varieties to grow. A market orchard must produce good fruits in abundance, and those of fine colour, shape, size, and flavour. Planting a large number of varieties was not the best method, unless a merely local trade was catered for. Low-headed trees were the best, he said, because of their convenience for all matters of cultivation—pruning, spraying, picking, etc. The English Paradise stock was advocated for apples and the quince stock for pears, as these encouraged early fruiting. Deep planting was to be avoided.

Varieties of apples advocated were early sorts to be sold straight from the trees, and good late sorts to be stored for late use. A fruit room should, the lecturer considered, be part of the equipment of a market garden orchard. He said that certain varieties liked certain soils, and were failures even in a limited area, if soil conditions were unsuitable.

In most fertile soils he had found that good sorts for the Northern counties were Beauty of Bath, Mr. Gladstone, Ben's Red, Summer Golden Pippin, Irish Peach, and Worcester Pearmain, for early use; James Grieve, Devonshire Quarrenden, Allington Pippin, and King of the Pippins were suggested for later use.

For early culinary apples he advised Early Victoria, Grenadier, Domino, Lord Grosvenor, and Golden Spire; with Bismarck, Lane's Prince Albert, Newton Wonder, Northern Dumpling, and Bramley's Seedling, for late use.

Good pears were William's Bon Chretien, Doyenne du Comice, and Durondeau.

For compact growing apples Mr. Chisholm advocated planting 8ft. apart in rows 10ft. apart. Young trees being built up needed more nitrogen than trees in full-bearing condition, with reduced quantities of phosphoric acid and potash, the reverse holding good in the case of older and bearing trees. The use of lime was advocated to contract the acidity of most freely-manured market soils; this making the use of manures at a later date possible.

Mr. W. B. Little, Horticultural Instructor to Cumberland and Westmoreland, who followed, covered very much the same ground as Mr. Chisholm. He believed there was room for a great expansion of fruit culture, especially apple culture. At present, judging from the retail prices asked, someone got a good profit, although the grower frequently said he was losing money. Mr. Little said anyone entering on fruit culture for profit should have had experience. The site selected should be well drained; the soil well prepared by ploughing and sub-soil ploughing, or bastard trenching, and he said planting after a corn crop was usually successful. He urged planting Lane's Prince Albert on the crab stock to secure free growth, as the variety always formed fruit spurs abundantly. In a general way, however, he advocated the paradise stock for general use, and emphasised the need of firm planting. Canker was a trouble in Cumberland and Westmoreland, though American Blight was not so, therefore varieties not addicted to canker should be selected.

Early dessert varieties he advocated were Beauty of Bath, Mr. Gladstone for the north, with Worcester Pearmain; James Grieve he was not so satisfied with. Early Victoria, Domino, and Golden Spire were his selection for early culinary varieties. Lord Grosvenor was good on light soils. He thought the small experimental plots under the County Councils did not provide sufficiently exhaustive trials, and so he was careful not to condemn certain varieties. Allington Pippin and Fearn's Pippin he advocated for late dessert use, with King of the Pippins on light soils. Cox's Orange Pippin he did not speak highly of for general planting in the north, except as single cordons. Bramley's Seedling, Newton Wonder, and Lane's Prince Albert were Mr. Little's choice for late culinary varieties.

Mr. Little advocated the intermingling of trees, instead of planting in blocks, so as to secure cross pollination, so many apples, etc., being unfertile to their own pollen. If young trees were planted in October they might be pruned back the following February or March; if planted later pruning should be deferred for a year. Mr. Little followed with advice on spraying, and the need of keen investigation into insect pests and fungus diseases. Pears, he said, were hardly worth cultivation in the north for market purposes, but he strongly advocated the extended cultivation of damsons and plums in the northern counties. Black currants and gooseberries he thought should be more grown, especially in connection with fruit bottling.

Mr. W. Lawrensen, who opened the discussion, spoke of the fine quality of the hardy fruits cultivated along the Tyneside district. There was great need for shelter, and he strongly advocated beech hedges for this purpose. He also referred to the use of the Siberian Crab as a parent for varieties of apples suitable for the north, and said how finely coloured were fruits from seedlings of this crab, resulting from pollination by garden sorts,

Mr. J. Robson referred to the fact that there came into Newcastle each year at least 62,185 cwts. of apples, so that there was a ready demand for good fruits. He had grown many varieties, but considered only fifteen or eighteen were really suitable, commercially, for the northern counties. He emphasised Mr. Lawrensen's remarks as to the ability of Tyneside to grow apples, but added that sites chosen for planting should be 200ft. above sea-level, and then, with some shelter from the north and east, fine samples could be grown, and the business be a remunerative one.

HORTICULTURAL EDUCATION.

At the second afternoon session, commencing at 5.30 on Wednesday, November 15, the subject for consideration was "Horticultural Education," with special reference to certificates, diplomas, and degrees. Dr. W. H. Hadow, Principal of Armstrong College, presided.

Mr. F. J. Chittenden, Director of the Laboratory, Royal Horticultural Society's Gardens, Wisley, opened the proceedings, and said that horticultural education was now exciting a great deal of interest, and this was evidenced by the work done under the County Councils, and at the instance of various colleges. It was a matter discussed at meetings of gardening societies, and was exercising the minds of those conducting the British Gardeners' Association and the North of England Horticultural Society. At Wisley, Kew, Glasnevin, and Edinburgh young men were being trained for the horticultural profession. The North of England Horticultural Society was taking a very keen interest in the matter, as evidenced by the present conference. He found that horticulture was often swamped by her sister, Agriculture, but horticulture was now the greatest of the minor industries. The term "Gardener" should include all those who gained their livelihood from horticulture and its practice, and not merely one employed in a private garden. An agriculturist had, he said, about a dozen kinds of plants, and half a dozen kinds of animals, but a gardener had enormous numbers of plants, fruits, and vegetables to deal with. A sound elementary education must be the foundation. A young man must be skilled in mind and hand. Mere technical skill would make a good practical man, and he would work well under regular conditions, but yet be something of a machine, and would often fail when new conditions obtained. The scientific training gives this "something more," and ensures to the skilled technical man a greater success in his profession. If technical skill alone was likely to result in failure, a scientifically skilled man would be even more likely to fail, if he possessed that skill alone. Most clever gardeners possessed both scientific training and technical skill, but often disclaim the former unwittingly.

A young man should have an early training at a nursery, to understand that hard work is necessary, and here he would be well grounded in practical work. Next should come a two-years' course at an establishment where he could be scientifically trained, and also be trained in technical work, at the same time; the two kinds of training must run concurrently.

In place of a college course a good deal could be done by attendance at evening classes, where scientific matters relating to horticulture were taught by skilled teachers.

With relation to certificates of proficiency Mr. Chittenden felt unable to speak authoritatively. At present about the only certificate granted was the one issued by the Royal Horticultural Society to those who passed its examinations. A national diploma would be a grand advance, and this seemed to be in view. It would mean the formation of an Institute by a limited number of skilled horticulturists, and the entrance by means of examinations open only to those who had spent a given number of years in practical work and scientific training.

Mr. P. P. Walker, lecturer in agriculture at the Armstrong College, said a college course of training should not be such as to place a man above his work. No amount of education in sciences would do away with the necessity of hard practical work. If all agriculturists could be raised to the level of the most successful farmer then the nation would gain materially. All successful men were men of education (in the broadest sense), though they often disclaimed educational advantages. Such a successful man was one who concentrated attention upon effect of season, soil, etc., a keen observer, and a man always well ahead with his work.

A careful study of, and training in, the scientific rules underlying the practice of horticulture and agriculture was necessary if a man was to become highly successful, but to show that a college course of study was a great advantage it was necessary to show that a man so trained could produce greater returns on the farm or in the garden on his return to the business of life. The college course should be the means to an end; not an end in itself. College education should also shorten the time needed to gain the highest practical experience. In the case of gardening, he said, wages depended upon efficiency, and in private gardening there was no need for capital other than brains He urged that young gardeners should attend gardening associations and combine to obtain educational facilities from the constituted authorities. The experimental farm or garden was not, however, in his opinion, the best place for gaining technical education.

At present most instructors in horticulture were successful head gardeners, and they did excellent work, but they needed a sounder basis of scientific instruction. A man knowing nothing of chemistry could not properly appreciate the value of chemical fertilisers. An instructor should not disregard proper educational methods. He considered the first duty of gardening societies or other interested bodies to see that their instructors obtained diplomas, and these could only be obtained as a result of a college course, and be of value when the examining body was composed of specially trained men. He believed that if courses of training could be arranged and diplomas or degrees granted, that the successful men would be able to command a far better wage than at present.

Mr. G. P. Berry, Horticultural Instructor to the Edinburgh Agricultural College, outlined the courses of instruction laid down in Scotland for the education of gardeners, and we understood him to say that already eight head gardeners had entered for a two-years' college course. They hoped very soon to secure a garden wherein all practical work could be done in conjunction with the teaching in the class-room. But Mr. Berry pleaded strongly for Governmental assistance, so that selected men might, by means of examinations and scholarships, be able to take a two-years' college course, for, as he rightly pointed out, at present it was only the son of a very successful private gardener, nurseryman, or market grower who could afford to take advantage of such skilled training.

Mr. Hosking, Horticultural Instructor to the Glasgow Agricultural College, said that what was needed was that gardeners should be educated, not that educationalists should be turned into quasi-gardeners. He had hoped Mr. Chittenden would have placed before them a plan whereby a gardener could be properly trained so as to secure a certificate or diploma that would be a mark of his ability; he was disappointed, and yet he thought the Royal Horticultural Society or the Board of Education might find a way out of the difficulty. At present he thought the Institute of Gardeners, as suggested, seemed to be the best method of hall-marking the capable men.

EARLY CHRYSANTHEMUMS.

Mr. W. R. Armstrong presided at the evening session on the opening day, and there was a moderate attendance to hear a lecture on "Early-Flowering Chrysanthemums" by Mr. J. Smith, Horticultural Instructor to the Durham County Council, who took this subject in the unavoidable absence of Mr. J. F. Donoghue, of Leeds.

FRUIT BOTTLING.

During the afternoon of November 16, at three o'clock, or thereabouts, Dr. Stewart presided, and, in a brief, interesting, and humorous little address, commending fruit bottling and the increased consumption of fruits, introduced Mr. Chisholm, who gave a very lucid lecture on "Fruit Bottling," which we hope shortly to publish in extenso. Mr. Chisholm had a cooker and bottles present, and showed how these were used.

SOIL BACTERIA AND SOIL STERILISATION.

Professor Gilchrist, of Armstrong College, presided over a capital meeting held in the Council Chamber at the Town Hall, at five o'clock on November 16. This was a very successful session.

The subject of "Soil Bacteria" was taken by Mr. F. J. Chittenden, of Wisley, who pointed out that soil was not only a combination "of stones and dirt," but material densely populated with living things, many of them, the bacteria especially, being present in enormous numbers, and among the smallest of living things. Bacteria were chiefly present a few inches below the surface, and individuals measured about the twenty-thousandth of an inch across. In a gramme of soil there would be upwards of fifteen millions of bacteria; the larger the amount of decayed animal and vegetable matter in the soil, the greater the numbers of bacteria. Bacteria were not all harmful—that was a common fallacy. The rate of bacterial increase was wonderful, and it took place by division, and two would be formed from one in a half-hour, and each new bacterium could again increase at a like rate. A little arithmetic would serve to show the enormous multiplication from one bacterium in twelve hours.

Organic matter in the soil, and a temperature of 75 degrees were conducive to rapid multiplication. Some kinds of bacteria would grow without air, and these were not useful in soils, but those needing air were useful from the cultivator's point of view. Over-multiplication of bacteria tended to check a great excess, because of the waste products and their consequent reaction upon bacterial life.

Bacteria were able to break down the complex materials in the soil. We live, he said, at the bottom of an ocean of nitrogen (four-fifths of the air is nitrogen), and yet are unable to use it directly. Plants can only take in nitrogen by means of nitrates and compounds of ammonia. In the soil one set of bacteria might be called "ammonifiers" as they produce ammonia. Nitrification, or the formation of nitrates, takes place by means of the "ammonifiers" first producing ammonia; another set of bacteria will produce nitrites from this ammonia; while yet a third set of bacteria takes the nitrites and converts them into nitrates, for the benefit of the plants growing in the soil.

The soil must contain nitrifiable matter, such as farmyard manure, and green manures; it must also be sufficiently moist and contain an abundant supply of air or the useful bacteria could not work: the temperature must be from 75 to 80 degrees; there must also be a base, such as lime, to work on. The better a soil is worked, said Mr. Chittenden, the more fertile it usually is, and this was due to aeration, and the consequent increase of useful bacteria. In well-worked soil useful bacteria were seventy times more numerous than in unmoved soil. In waterlogged soils a set of harmful bacteria lived practically without air, but these could not live in freely-worked aerated soil.

The nodules on roots of leguminous plants are, he pointed out, the homes of bacteria that are in partnership with the green plant and pass on to it the nitrogen they extract from the air, in a condition in which the plant can use it. It is due to this fact that leguminous crops always leave a soil richer in nitrogen than it was previously.

STERILISATION OF SOILS.

This subject was dealt with by Mr. S. H. Collins, M.Sc., of Armstrong College. He briefly referred to bacterial multiplication, and showed that "sterile" as referred to soils meant a soil incapable of reproducing its bacterial content. It was well nigh impossible, however, to absolutely sterilise a soil. Excess of water, and also lack of water both tended to soil sterility, and therefore to poor, or absence of, plant crops. Lime, he said, was necessary to bacterial production, and to the reduction of certain objectionable substances in the soil. Gaslime would destroy many harmful bacteria as well as other larger and harmful living bodies. He referred to soil amoebæ, which, he said, ate up bacteria, good or bad, but if the former were destroyed then also many useful bacteria would be destroyed at the same time, but the useful bacteria could multiply quicker and so get ahead of the few remaining amoebæ.

Steam heating of soils encouraged crop fertility because it destroyed a vast number of the minute soil inhabitants, and gave those strong and helpful bacteria that remained a fine chance, as so many amoebæ (their natural enemies) were destroyed in the process.

Mr. Collins said: Frost has something of the same action as considerable heat, but it was more severe upon the larger forms of minute life, the amoebæ, for instance, than on the useful bacteria. There was, he said, nothing better than heat to produce great chemical changes, and the effect of heating soils by steam was to set free soluble plant foods. "Sick" soils, if steam-heated, may often be made fruitful, because of the destruction of amoebæ, and toxic substances. Mr. Collins said he hoped the theoretical knowledge already obtained in connection with soil bacteria and sterilisation might be used with practical effect, so that "sick" soils, such as occur in commercial horticulture all too frequently, might be made clean and fruitful for a succeeding crop.

AMERICAN BLIGHT AND BIG BUD MITE.

Mr. R. A. H. Gray, M.A., of the Armstrong College, had a subject, or subjects, of great economic importance in the fruit-growing industry to deal with, and we hope to reproduce his notes on these pests in an early issue.

In the discussion that followed, Mr. H. Britten, of Penrith, showed the great need of special care and some oversight in efforts made to check woolly aphis, because of the presence of the pest on innumerable crab apple trees in the hedgerows in many parts of the country. He said that the woolly aphis found on lettuce roots was not American blight, and not harmful to apples.

Mr. Harris wanted a cure for eelworm; he had little faith in the talk about sterilisation, the steam heating of soils, and the like, as the few methods at various times suggested were all too expensive. Mr. Harris evidently wanted someone to wave a magic wand over his eelworm-infested soil and make it clean. He said he had had but half a crop of tomatoes owing to "sick" soil—it would surely pay him to sterilise his soil by heating, rather than continue to obtain half crops or import new soil. Mr. Harris had evidently little faith in "science," and left the room, apparently a very disappointed man.

Soil fumigants and insecticides were referred to by several speakers. One gentleman said that a certain grower who obtained the best prices in Newcastle Market for black currants, kept big bud at bay by very hard pruning and good feeding, so that he continually obtained new strong growth right from the base of the plants, and so reduced infestation to a minimum, and secured splendid fruits.

Mr. Chittenden said he regretted Mr. Harris had left, because he could have told him that heating the soil to boiling point would kill all the eelworms. Mr. Chittenden was emphatic in his belief that legislation was of no real use in dealing with insect pests: education and proof that certain measures meant increased crop production were the only proper means.

THE GREAT WINTER SHOW
will be held in
THE ROYAL BOTANIC GARDENS,
on
DECEMBER 5 and 6, 1911.
Admission 1s.
Schedules and particulars from
E. F. HAWES,
Imperial School of British Horticulture, West Hampstead, N.W.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C

Mr. Collins replied to one or two points raised, and Mr. Gray expressed his belief in legislative measures for the suppression of insect pests, and to protection against the importation of insect and fungoid pests by means of imported plants.

Professor Gilchrist brought the proceedings to a close by moving a vote of thanks to the lecturers, and observing that it was not possible to properly deal with any pest until its life history was known. He expressed the pleasure it gave him to be present, and he hoped that other congresses of similar character would be held in the near future.

Mr. H. J. Chapman referred to the forthcoming International Horticultural Exhibition, and said he hoped the local committee would, at the close of that great exhibition, combine to form a horticultural society of real worth in the Newcastle district.

National Dahlia Society.

At the annual general meeting of this society, held at the Hotel Windsor, Victoria Street, Westminster, on November 28, there was not a large attendance, but the officers and committee were strongly represented.

Mr. George Gordon, V.M.H., was voted to the chair. The formal business having been disposed of, a letter was read from Mr. Edward Mawley, V.M.H., who, because of illness, withdrew from nomination for the presidency of the society. The Chairman, in a few appropriate words, moved that a record of appreciation of Mr. Mawley's great services to the society, over many years, be entered on the minutes, and that a suitable letter be sent to Mr. Mawley.

The Chairman then moved the adoption of the report and financial statement, and, in doing so, reviewed the year's work, and said that under all the peculiar circumstances of the year, the members had every reason to congratulate themselves upon the position of the society. He pointed out that the society should not exist for the advancement of any one section of dahlias, but it should cater for all sections, both for exhibition and for garden decoration, and so secure the interest of the great flower-loving community, and thereby add to the membership of the society, and place it in a higher position among floriculture societies devoted to a special flower. He hoped the time would soon come when these would again be held with suitable prizes.

REPORT OF THE COMMITTEE FOR 1911.

Your committee have pleasure in submitting their annual report of the work of the society for the year 1911.

Following the precedent of last year, a Conference was held at Carr's Restaurant, Strand, London, W.C., on Friday, March 17, 1911, when Mr. Edward Mawley, V.M.H., president of the society, occupied the chair. Two excellent papers were read on "Single Dahlias: Their Cultivation and Use," by Mr. Joseph Cheal, and "Decorative Dahlias, with Special Reference to Their Early and Abundant Production of Bloom," by Mr. George Gordon, V.M.H. The papers were followed by a brisk discussion, and subsequently published in the horticultural Press, and the year book of the society.

Your committee arranged for two exhibitions to be held during the year, at the Crystal Palace, on September 7 and 8, and at the Royal Botanic Gardens, on September 20 and 21. The dry season had considerable influence upon the early production of bloom, and under these circumstances the exhibitors were not so numerous as in the preceding year, but the quality of the blooms shown was of a high order.

An extensive series of trials was carried out by Messrs. H. Cannell and Sons, at the Home Nurseries, Swanley, and on the committee's visit, which was postponed until October, the flowers were in excellent condition. The trials brought into prominence the best varieties for garden decoration, and the report thereon by the Committee of Inspection will be published in due course.

After the luncheon, which was held in the Fellows' Rooms, at the Royal Botanic Gardens, on September 20, the medals and cups which had previously been won at the Crystal Palace, were presented by the President, Mr. Edward Mawley, V.M.H., who occupied the chair; this function proved a most enjoyable one.

In order to assist the society in its work, members of the trade most generously decided to forego their prizes in the nurserymen's classes for the present year. By this means the society has been able to carry out its work during the year, and now has a balance on the credit side.

Over twenty new members joined the society during the year, and the majority took part in the exhibitions. Many still regard the society in a purely exhibition sense, and only become members in order to exhibit. Your committee would again urge the importance of securing new members, who will continue as annual subscribers, whether exhibiting or not, as such members form the real strength of a society.

Your committee, fully recognising the quality and importance of all types of the dahlia, still continue to give attention to the decorative aspect of the flower, and several certificates have been awarded to decorative dahlias during the year.

Your committee have offered a gold, a silver-gilt, and a silver medal to be awarded to dahlias at the Royal International Horticultural Exhibition of 1912. Your committee recommend that only one exhibition shall be held during the coming year.

The hearty thanks of the society are accorded to all those who have so ably and readily assisted the committee, either as donors of special prizes, by reading papers at the conference, judging at the exhibitions, to the Crystal Palace Company, the Royal Botanic Society, Messrs, H. Cannell and Sons for conducting the trials, and to the Horticultural Press for their kind and willing assistance on all occasions.

The financial statement showed an income of £128 14s. 3d., including £73 1s. 4d. from subscriptions. The cash balance remaining was £8 6s. 6d. The balance-sheet showed a balance of £18 1s. 7d. in favour of assets.

The motion was seconded by Mr. S. Mortimer, and adopted unanimously.

A slight alteration of the rule relating to the Annual Meeting was made, permitting the committee to fix the date on any day that seems desirable in November. A vote of thanks to all retiring officers was then carried. On the motion of Mr. S. Mortimer, seconded by Mr. J. Cheal, Mr. George Gordon, V.M.H., was unanimously elected president for the ensuing year. Mr. E. Mawley was added to the list of vice-presidents, and all other holders of such office were reelected. Mr. John Green was again elected treasurer, and Mr. E. F. Hawes was again appointed hon. secretary, and he was voted an honorarium of £8 as a small appreciation of services rendered. Mr. W. Stephens was re-elected auditor, and the committee was also largely re-elected.

Mr. Joseph Cheal was unanimously elected chairman of committee for the ensuing year, and a vote of thanks to Mr. Gordon for presiding concluded the proceedings.

Winchester.

NOVEMBER 14 and 15.

The twenty-ninth annual autumn display was held in the Guildhall—a capital site—and if not quite so extensive as in some past seasons, it was quite equal in point of quality. No finer cut blooms of chrysanthemums have been seen anywhere this season, especially the incurved. Plants are here a feature, especially those grown for conservatory decoration, which were remarkable for the high quality of their blooms rather than the number. Fruit and vegetables were noteworthy features of the show.

PLANTS.

For a collection of chrysanthemums, arranged in a space eight feet by seven feet, with an edging of foliage plants, there were but two contestants. Mr. A. J. Marsh, gardener to M. Hodgson, Esq., Martyn Worthy, Winchester, was distinctly first with rather tall plants carrying excellent blooms, effectively arranged. Mr. W. Pearce, gardener to H. Johnson, Esq., Northgate Place, Winchester, second, with dwarf plants, more freely flowered than the premier exhibit. For nine specimens, each to carry not less than five blossoms, there were four contestants, producing quite a fine display. Mr. E. Cousens, gardener to J. A. Fort, Esq., The College, Winchester, was first with dwarf examples, carrying really fine blooms, of F. S. Vallis, W. Mease, Mdme. R. Oberthur, Mrs. Judson, and Bessie Godfrey; Mr. G. Adams, gardener to Colonel Dickins, Edge Hill, Winchester, second. In a class for nine plants of any white or yellow variety, Mr. Cousens again led with capital examples of Embleme Poitevine, Mrs. Judson, F. S. Vallis, and Mdme. Orberthur being the most noteworthy; Mr. C. White, gardener to Captain Clayton Mitchell, West Highlands, Winchester, second. Mr. A. J. Marsh had the best six decorative plants, any colour, showing Caprice du Printemps, Kathleen Thompson, and Mdme. R. Orberthur as the best. Mr. F. W. Stone, gardener to the Rev. A. G. Bather, Sunnyside, Winchester, second.

Amateurs showed well in several classes. Mr. A. E. Taylor, Hillside Terrace, Winchester, won for three decorative plants with freely-flowered specimens. The best group of miscellaneous subjects, arranged for effect, came from Mr. J. Hayes, gardener to Mrs. Arbuthnot, St. Phillip's, Sleepers Hill, Winchester.

CUT BLOOMS.

The leading class was for twenty-four Japanese, in not less than eighteen varieties. Mr. C. Moore, gardener to Mrs. G. Clarke, Frensham Place, won with full, solid, highly-coloured, fresh specimens of well-known varieties. Five competed for a dozen Japanese, and Mr. C. Moore again secured the premier award; Mr. F. Neville, gardener to Admiral the Hon. W. G. Stopford, Ashe House, Overton, a close second. For six Japanese, three blooms of each, in vases, Mr. A. J. Marsh won easily with huge specimens; Mr. Moore second. The best five blooms, any white variety, came from Mr. A. J. Marsh, amongst six competitors, handsome examples of Evangeline; Mr. F. Rowe, gardener to J. Ridley Shield, Esq., Carden, Alresford, second.

Incurved were, as usual, of fine quality, the late date suiting this section. For twenty-four, in not less than eighteen varieties, Mr. Marsh was distinctly ahead with bold, handsome blooms; Mr. C. Moore second with blooms a trifle smaller. Mr. Marsh won the premier place for twelve with a set of clean, smart flowers; Mr. D. Edwards, gardener to W. Garton, Esq., Salisbury Court, Southampton, second.

Single-flowered varieties, undisbudded, formed a delightful feature. For six, distinct, Mr. A. J. Marsh had the best of six sets; Mr. G. Grant, gardener to G. H. Kitchin, Esq., Compton, Winchester, second. For the same number of any undisbudded decorative variety, except singles, Mr. A. E. Taylor was easily first with handsome bunches; Mr. G. Barnes, gardener to T. C. Wilson, Esq., The Thickets, Bishop's Waltham, second, with good blooms very poorly arranged.

FRUIT.

For two bunches black grapes, Mr. Ellwood, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, was first with Alnwick Seedling, good in bunch, berry, and colour. In a similar class for any white grape, Mr. T. Hall, gardener to Ellen Lady Swaythling, South Stoneham House, Southampton, was first with Mrs. Pearson in good order.

Dessert apples in four dishes were a grand display, fourteen taking part. Mr. W. West, gardener to Mrs. Knox, Holt Hatch, Alton, was first with remarkable specimens of Cox's Orange Pippin, Ribston Pippin, Blenheim Pippin, and Allington Pippin; Mr. Barnes second. Mr. Learmouth, gardener to J. Liddell, Esq., Sherfield Manor, Basingstoke, won the coveted award for the same number of dishes, kitchen varieties, with huge Peasgood's Nonsuch, Bramley's Seedling, Newton Wonder, and Annie Elizabeth.

Mr. Ellwood easily won the leading position in the three trade classes for vegetables in six dishes with exceptionally fine leeks, onions, celery, tomatoes, cauliflowers, and potatoes; Mr. Barnes was second, in a stiff competition.

Blackburn.

The annual exhibition of this society was held in the Town Hall, Blackburn, and the entries were good. As usual, orchids were the most important section of the show, the classes being well filled with beautiful and interesting forms.

In the class for a table of orchids and foliage plants, covering a space about 10ft. by 6ft., two collections were staged, very similar in outline, and about ten feet in height; the premier lot was set up by Mr. H. H. Tindall, gardener to W. Duckworth, Esq., and included many fine cattleyas, cypripediums, odontoglossums, etc., these being surrounded by a bold group of Oncidium varicosum Rogersi, its spreading sprays of golden blooms producing a beautiful picture. Mr. J. Lupton, gardener to Colonel J. Rutherford, M.P., Blackburn, was second, the fine spikes of his odontoglossums showing good cultural skill. Mr. Charles Parker, Preston, staged a table of cypripediums, using small plants of good varieties, and these gave him the leading position ;Mr. J. Walmsley was second with a highly creditable selection.

For three cypripediums, Mr. J. Pimlott, gardener to T. Mitchell Eccles, Esq., J.P., led the way, having good examples of C. insigne Harefield Hall, and C. i. Sanderæ. For three hybrid orchids, Mr. S. Hardy, gardener to Harry Bell, Esq., J.P., was first; and Mr. J. Pimlott excelled with four plants. Mr. C. Parker had the best single specimen cypripedium, and Mr. H. H. Tindall for the best orchid with Cypripedium Spicerianum.

Mr. H. Shutt was successful for his table of flowering begonias, and Mr. H. Bradburn, gardener to J. Wilcock, Esq., J.P., scored for six table plants in a large entry; Mr. K. McCullock, gardener to Mrs. Astley, led for six primulas with good plants of P. obconica. Mr. H. Bradburn occupied a fine position with his group of chrysanthemums arranged for effect, which included a number of fine Japanese varieties. The arrangement was large and effective. On either side of this exhibit was a group of singles, and here Mr. C. Samways, gardener to J. Thompson, Esq., the silver champion vase which he so well deserved; Mr. J. Pimlott was a worthy second; and for the group of miscellaneous plants he succeeded in taking the first prize.

In the classes for chrysanthemums in pots, Mr. H. Bradburn came out in strong form, winning for six singles, four large-flowering, and one Japanese, showing moderate plants throughout. Mr. Pimlott had the best incurved, and Mr. Samways the leading single variety. Mr. J. Bartlett, gardener to H. Smith, Esq., contributed a fine half-dozen well-berried solanums; Mr. H. Bradburn led for four bouvardias; and Mr. Samways scored with six cyclamen and four amaryllis.

Vegetables were well represented, Mr. I. Parker, gardener to Mrs. Stones, staging the winning collection of eight kinds.

Cut blooms were generally moderate in size, but fresh, and good in colour. Mr. H. Bradburn won in the premier class for twenty-four Japanese blooms; Mr. J. Mundell, gardener to H. Smalley, Esq.; and Mr. H. Boyd, gardener to Captain Fielden, coming second and third. For twenty-four blooms, twelve Japanese and twelve incurved, the prizemen were Messrs. H. Boyd, J. Pimlott, and H. Jones. Mr. J. Pimoltt scored for the best dozen Japanese, and Mr. Jones for a like number of incurved varieties; this exhibitor also secured the two N.C.S. Certificates for the best Japanese bloom with Frances Jolliffe, and the best incurved bloom with Buttercup.

The ladies' section was well filled, Mrs.Pimlott having the best basket of chrysanthemums, and the best basket of autumnal foliage, berries, etc. Mrs. Arthur was successful for a centrepiece suitable for a dinner table.

Fruit was not very extensively shown, but of good quality, Mr. C. Samways having the two best black bunches of grapes, with good Alicante; and Mr. J. Wright, gardener to E. Lord, Esq., the two best white bunches, with Muscat of Alexandria. Tomatoes were fine for the season, Mr. Thomas Smith being the foremost competitor.

Bedford.

The eighth annual chrysanthemum show held in the town of Bedford took place in the Corn Exchange. The building is a excellent one for a show, being capitally lighted and well designed. The exhibition was not a very big one, but it was very pretty and of great interest. Cut flowers were fairly good, the singles, in vases, being especially fine; groups and plants added to the effectiveness of the display, while splendid apples in large numbers and a capital lot of vegetables were fine features. Messrs. Laxton Brothers contributed a collection of splendid apples; Mr. Garner showed a number of new chrysanthemums, and Messrs. Cooper and Sons put up an excellent collection of vegetables; so the local nurserymen did their share in providing a display.

GROUPS AND PLANTS.

In the leading class for a group of chrysanthemums displayed on 50 sq. ft., the premier award went to Mr. R. Day, gardener to T. E. Hurst Hodgson, Esq., St. Mary's Abbey, who displayed Japanese and incurved varieties in the orthodox style, and finished off his group neatly. The second prize was awarded to Mr. W. Wilsher, gardener to W. L. Fitzpatrick, Esq., J.P., for a charming exhibit, composed entirely of single varieties, and his group could not have been far behind the premier award.

Mr. Wilsher scored for a specimen plant with a huge example of Caprice du Printemps; Mr. R. Day coming second with a big Mary Richardson. Mr. R. Day led for six specimens, with large well-flowered bushes of single and decorative varieties, and he was followed by Mr. W. Wilsher, who had several plants not then at their best. In the cottagers' section Mr. Allen led for one specimen with a big bush of Edith Pagram.

In the amateur's division Mr. P. Wilsher, gardener to J. W. Wright, Esq., Burnaby Road, was the only exhibitor of a group of chrysanthemums, and he was worthily awarded the first prize for a very well-arranged set of well-grown Japanese varieties. Mr. W. Wilsher was the only exhibitor in the class for six specimens of Begonia Gloire de Lorraine; he was awarded the first prize for splendid plants.

CUT BLOOMS.

The best dozen Japanese blooms were from Mr. Thomas Tiddesley, Goldington, and his leading examples were Miss F. C. Stoop, Mrs. Charles Penford, Mrs. A. T. Miller, and Master David; Mr. F. Taylor, gardener to R. W. Allen, Esq., J.P., Blunham Grange, came second. Mr. W. Wilsher led for a dozen incurved blooms, and showed Clara Wells, Romance, Buttercup, and Embleme Poitevine in good style; Mr. P. Wilsher second. Mr. Thomas Tildesley was easily first in the amateurs', and single-handed gardeners' section for a dozen Japanese blooms, and here he had Miss F. C. Stoop, Master David, J. H. Silsbury, and Bessie Godfrey, in good form; Mr. P. Wilsher came second, and Mr. R. Mason, gardener to H. G. Hipwell, Esq., third.

The best half dozen Japanese blooms were from Mr. Thomas Tildesley, who also scored for three vases of Japanese blooms distinct, three blooms in each, his varieties being Master David, Bessie Godfrey, and Master James. Mr. C. Allen and Mr. C. Myers scored in the cottagers' classes for single flower vases, while in the open class for five vases of singles, six sprays in each, Mr. R. Day led with a splendid lot of Metta, Mary Anderson, Altrincham Yellow, Sylvia Slade, and Fair Rosamond; Mr. W. Wilsher came second, and Mr. J. Bates third.

The open class for three vases of Japanese blooms found Mr. F. Taylor to the front, with Mr. R. Day second. For one vase of five white Japanese blooms, Mr. H. Blakeney, gardener to W. H. Allen, Esq., J.P., Bromham House, won the chief honours with a superb set of glorious examples of Mrs. A. T. Miller, Mr. Taylor following for second place, and Mr. P. Wilsher coming third. Mr. Taylor and Mr. P. Wilsher were first and second respectively for a vase of five flowers of a yellow Japanese variety.

A class for a vase of five Japanese blooms and ten sprays of singles, arranged with appropriate foliage, was scarcely so attractive as it might have been, as sufficient care was not shown in the disposition of the flowers; Mr. T. E. Sinfield, gardener to Reginald Carter, Esq., was first, Mr. W. Wilsher second, and Mr. F. Taylor third. In a special class for a large vase of single varieties, Mr. W. Wilsher just managed to beat Mr. Day; both showed well, and a good competition in such a class would prove a great attraction at any show.

FRUITS AND VEGETABLES

There was a good competition in the grape classes, Mr. W. Wilsher coming first and Mr. P. Wilsher second for white varieties, two bunches, with Muscat of Alexandria. Out of five competitors for black grapes, two bunches, Mr. R. Day led with Alicante, nicely coloured; Mr. C. Cousins, gardener to G. D. Newton, Esq., Croxted Park, St. Neots, second, and Mr. W. Wilsher third with very big clusters of Lady Downes.

Apples were splendidly shown, and the premier set of four dishes of culinary varieties, from Mr. Cousins were beautiful examples of Peasgood's Nonsuch, Bismarck, Warner's King, and Gascoigne's Scarlet; Major Carpenter, J.P., Bidenham Close, second, and Mr. R. Day third. For dessert apples Mr. R. Day led with King of the Pippins, Mother, Ribston Pippin, and Cox's Orange Pippin; Mr. Cousins second, and Mr. R. Mason third. Mr. P. Wilsher, Mr. R. Day, and Major Carpenter secured the leading awards for pears.

Vegetables were finely shown and staged in large numbers. For Messrs. Sutton and Sons' prize Mr. F. Taylor was first, and Mr. C. Cousins second. Mr. R. Gardener, Mr. R. Day, and Mr. J. B. Robinson scored as placed in the society's class for six kinds of vegetables, while for nine kinds Mr. F. Taylor had matters all his own way. For Messrs. Laxton Brothers' prizes the winners in order were Mr. F. Taylor and Mr. R. Day, while for Messrs. Webb and Sons' prizes the awards fell to Mr. J. B. Robinson and Mr. R. Mason. Altogether in the several classes there were about two dozen collections of vegetables staged.

Single dish classes for vegetables were numerous, and parsnips, potatoes, beet, cauliflowers, leeks, onions, and celery were famously shown, but carrots were below the usual mark.

GRAPE CULTURE.—An illustrated guide to the culture and management of vines in greenhouses and in the open air is published at Gardeners' Magazine Office, 148, Aldersgate Street, London, price 1s. net (by post 1s. 2d.), or bound in cloth 1s. 6d. (by post 1s. 8d.). Full particulars are also given as to renovating old vines, and the best varieties to grow.

OBITUARY.

MR. JAMES DOUGLAS, V.M.H.

It is with the deepest regret that we have to record the death, at the age of 74, of Mr. James Douglas, V.M.H., which occurred at St. Nicholas' Hill, Leatherhead, on the 26th ult., after his having undergone an operation.

Mr. Douglas was throughout his long and active life so steadfast in his devotion to floricultural and horticultural pursuits, and, moreover, did such splendid work as to obtain for himself a commanding position in the world of horticulture and the esteem of all, and they are many, who have had the pleasure of his acquaintance. Hence it is that the announcement of his death will be received with profound regret by a large section of the flower-loving community. Mr. Douglas had of late years become best known as a florist, but it should be remembered that, although he has been chiefly concerned with florists' flowers during the past twenty years or so, he achieved in the course of his career success of a high order in every department of gardening. Mr. Douglas especially distinguished himself in the cultivation of fruits under glass, and many are the awards that were made at the leading exhibitions to the products of his skill. He especially excelled as a grape-grower, and was successful in the cultivation of pine apples, and it may be mentioned that the first prize he won was for a pineapple shown at Regent's Park in 1866. Mr. Douglas also took a keen interest in orchids, and achieved much success with them, both as a cultivator and exhibitor, during the long period he had charge of the gardens of Great Gearies, the residence of F. Whitbourn, Esq.

For upwards of forty years he was one of the leading cultivators of auriculas, and won prizes well nigh innumerable with them, and he was highly successful in the raising of new varieties, a considerable proportion of these occupying a high position in their respective classes. Mr. Douglas was not less successful in the raising, cultivation, and exhibition of carnations and picotees, and contributed largely to bringing the yellow-ground flowers to the high position they have attained within recent years.

While devoting close attention to the cultivation and improvement of his favourite flowers, Mr. Douglas found time to render valuable services in the cause of horticulture and to assist in the management of the gardening charities. In 1888 Mr. Douglas was appointed a member of the Council of the Royal Horticultural Society, and during the nine years that he retained his seat on that body he had the satisfaction of seeing the society reinstated in public favour, and entering on prosperous times. Mr. Douglas served for long periods on the Fruit, Floral, and Scientific Committees of the Royal Horticultural Society, and was a member of the two last-named committees at the time of his death.

THE LATE MR. JAMES DOUGLAS, V.M.H.

Mr. Douglas also served as a member of the Committee of the Royal Gardeners' Orphan Fund, and of the Gardeners' Royal Benevolent Institution. In recognition of the services Mr. Douglas had rendered to horticulture, he was awarded the Victoria Medal of Honour in Horticulture on its foundation in 1897. Those of our many readers who knew Mr. Douglas and his work will, we feel sure, join with us in offering our sympathy to Mrs. Douglas and family in their great loss.

TRADE NOTE.

Messrs. Richard Sankey and Son, Lim., Buiwell, Nottingham, have been appointed manufacturers of horticultural pottery to his Majesty King George. This long-established firm supplied Windsor gardens under Queen Victoria, and held the sole Warrant of Appointment to H.M. the late King Edward. We understand this is the only appointment of garden pottery manufacturers to King George.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

HEATER FOR PROPAGATING FRAME. A. F., Northumberland: Your suggestion is a very good one, and should be successful if you enclose the tank so that the heat is not wasted, but goes directly to warm the frame. There must be an escape pipe for steam to act as a safety valve, and over the tank a good layer of cocoanut fibre refuse must be placed on or in which the pots of seeds and cuttings will be placed. The great point will be to adjust your lamp so as to secure a steady and continuous heating, therefore everything should be ready some time before you commence propagating, so that, by means of a thermometer, you may discover the capacity of your heating apparatus, and know how to regulate the temperature.

DISQUALIFICATION AT WINNIPEG.—J. C., Winnipeg: We should have had the schedule before us before passing judgment, but, to save time, we give our opinion of the matter as set forth in your letter. A spruce fir may not be the sort of plant generally used in a class for "A group of foliage and other decorative plants," but the spruce is a foliage plant, and it is decorative in the garden, though scarcely handsome when grown for timber in forests. Moreover, who, among English-speaking peoples, ever questioned the decorative value of the spruce as a Christmas tree? We think you were wrong in disqualifying the exhibit that contained a spruce as centrepiece, and especially does it seem a pity you did so when you concede that the group containing it was the best in the show. The exhibitor must have been a clever man to be able to use such a plant successfully.

INFECTION IN TOMATO SEEDS.—S. A. S., Leeds: Bacteriosis in tomatoes and in potatoes is due to the work of an organism named Bacillus solanacearum. The disease is much more common in America than in the United Kingdom, but every effort should be made to keep it under. Not only are tomato stems infected by the disease, but bacteria have occurred abundantly in the substance of partly ripe tomatoes; hence, owing to the difficulty experienced in thoroughly removing the glairy coating from the seed, it is highly probable that bacteria would become locked up in this substance as it dried round the seed, and on being released during germination would endanger the crop. Seed obtained from fruit grown in an infected area should therefore not be used.

WORKMEN'S COMPENSATION ACT.—A. G. R., Monmouth: We cannot enter into the whole question involved, and we, therefore, urge you to obtain a copy of the Act and also Leaflet No. 255, issued by the Board of Agriculture, post free on application, to 4, Whitehall Place, London, S.W. But we may state briefly that the object of the

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price 10/6. Sole proprietors and manufacturers Robinson Bros., Ltd. West Bromwich.

PINE SPRAY SYRINGE patent

Workmen's Compensation Act, 1906, is to make some provision for employees who, through accidents arising out of and in the course of their employment, are disabled from earning their ordinary wages, or if the accident results in death, for any persons who are dependent upon the deceased. To effect this object, the Act makes the employer liable to pay compensation for such accidents. If the accident causes permanent or temporary disablement, the compensation will be in the form of weekly payments to the injured person while the disablement lasts; if the accident results in death, the compensation will be a lump sum to be applied for the benefit of such members of the family of the deceased as were dependent upon his earnings at the time of his death. The Act does not require employers to insure against these liabilities, but it is advisable that any employer who would find it difficult to meet the heavy charge which might be entailed upon him by a serious accident, should protect himself by insurance with a sound insurance company. There are two classes of injury for which compensation is payable under the Act: (1) Injury by accident; (2) injury to health from industrial disease. As regards injuries by accident the Act lays down the following conditions: (a) The accident must arise out of the employment, i.e., it must be directly due to the injured person's employment, and it must also happen in the course of the employment. (b) The injury must disable the injured person for a period of at least one week from earning full wages at the work at which he was employed. (c) If the injury is proved to be due to serious and wilful misconduct on his part, no claim to compensation is to be allowed unless the injury results in death or serious and permanent disablement. The word "accident" has been interpreted by the Courts in a wide sense, the House of Lords defining it in a case under the Act of 1897 as "an unlooked-for mishap or untoward event which is not expected or designed" (Fenton v. Thorley, 1903, A.C. 443).

INSECTS ON CYPRIPEDIUM LEAVES.—T. S. P., Bolton: The spotting on the undersides of the leaves is due to the presence of yellow thrips, and several of these pests were found in a very lively condition. You should lose no time in cleaning the plants thoroughly, because once thrips become numerous in a plant house they are not easily exterminated. Sponge the leaves with warm soapy water, to which some approved insecticide has been added. Fumigate the house by means of a vaporiser, and do this once a week until thrips cease from troubling. We may add that the presence of thrips suggests a rather dry atmosphere, as the pests flourish more in a dry atmosphere than in a moist one.

NAMES OF PLANTS.

F. E. G., Weymouth.—Arbutus Menziesi.

O. S., Shrewsbury.—1, Cattleya Fabia; 2, Odontoglossum ardentissimum.

E. J., Exeter.—1, Selaginella Mertensi; 2, S. apoda; 3, S. cæsia; 4, S. Kraussiana aurea; 5, S. Emileana; 6, probably S. hæmatodes.

L. B. C., Corbridge.—1, not recognised, send when in flower; 2, Calceolaria Burbidgei; 3, Hepenthes Morganiæ; 4, Euphorbia splendens.

M. W., Salisbury.—1, Pernettya mucronata; 2, Leycesteria formosa; 3, Solanum melongena; 4, Plumbago rosea; 5, Cypripedium Leeanum; 6, C. Arthurianum.

NAMES OF FRUITS.

P., Wimbledon.—Worcester Pearmain.

F. B. R., Royston.—Yorkshire Beauty.

R. T., Rhoden.—Lady Henniker. Name and address should always be sent as evidence of good faith, but not necessarily for publication.

J. T., Chilworth.—1, Claygate Pearmain; 2, Fearn's Pippin; 3, not recognised; 4, Margil; 5, not recognised; 6, Lemon Pippin; 7, Lord Grosvenor.

T. L., Byfleet.—1, Adam's Pearmain; 2, not recognised; 3, Kentish Fillbasket; 4, Damelow's Seedling; 5, Fearn's Pippin; 6, probably French Crab; 7, Beurre Rance.

CATALOGUES RECEIVED.

T. H. DIPNALL, HADLEIGH, SUFFOLK.—Mr. Dipnall issues a neat and handy list of sweet peas, together with classification and cultural notes, and list of too-much-alike varieties.

WILLIAM FELL AND CO., HEXHAM.—A very useful and comprehensive catalogue of forest trees, covert plants, avenue and specimen trees, flowering trees and shrubs, fruit trees, and roses.

H. HEMUS, HOLDFAST, UPTON-ON-SEVERN.—Miss Hemus's catalogue of sweet peas includes coloured illustrations of Orange Paradise, Paradise Celestial, Marjory Hemus, and Lavender Paradise. The catalogue is specially interesting because of the careful descriptions of varieties, and because of the offer of several stocks of a number of varieties raised at Holdfast Hall.

C. F. A. VAN DER SLUYS, RAMEE, GUERNSEY.—A concise and freely illustrated catalogue of select varieties of perpetual carnations. Many useful cultural hints are included.

FORTHCOMING ENGAGEMENTS.

MONDAY, December 4.—National Chrysanthemum
Society's Floral Committee at Essex Hall,
Strand; Chrysanthemum Conference at Carr's
Restaurant, Strand, W.C., at 7 p.m.
TUESDAY, December 5.—Royal Horticultural So-
ciety; committees meet at 12 o'clock; lecture at
3 p.m. on "Climbing Plants as a Biological
Study," by Professor J. B. Farmer, F.R.S
Scientific Committee at 4 p.m.
Horticultural Club House Dinner at Hotel Windsor,
Victoria Street, at [illegible], followed by a lecture
by Mr. Arthur W. Sutton, J.P., V.M.H., entitled
"Four Hundred Miles on Horseback East and
West of the Jordan.
Perpetual Carnation Society; exhibition at Royal
Botanic Society's Gardens, Regents' Park (two
days).
Scottish Horticultural Association meeting.
THURSDAY, December 7.—Linnean Society.
FRIDAY, December 8.—National Sweet Pea Society
annual meeting at Hotel Windsor, Victoria
Street, Westminster, at 2 p.m.; dinner at 6
o'clock; Sweet Pea Conference at 7 o'clock.
MONDAY, December 11.—United Horticultural Bene
fit and Provident Society, committee meeting.
WEDNESDAY, December 13.—North of England Hor-
ticultural Society, meeting at Leeds.
National Rose Society, annual meeting at the West-
minster Palace Hotel, Westminster, at 3 o'clock;
conversazione at 4.30.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Morphology.

The study of morphology, dealing as it does with the changes in organic life which have led up to adaptation to an infinite variety of environmental conditions, is of intense interest both to students of vegetable and animal life. In the plant world, complex as it is, there is a much greater simplicity than in the animal one, its method of growth, assimilation of nutrition, and general conditions of existence being on very different lines. Primarily it is beyond all doubt that the organisms of both kinds, animal and vegetable, were extremely simple in form—single cells or cell aggregations on simple lines—but in these simple organisms there was implanted a power to vary and become more and more complex in structure, until in process of time we arrive at the marvellous diversity which now occupies, and almost pervades, the earth's surface to a comparatively shallow depth, while doing the same in the ocean to a far greater one. These changes it is the province of the morphologist to follow up or retrace, and it is by virtue of such research that we have discovered that practically all organic life consists of one vast network of ramifying system, starting, in all probability, from a single vital stem, which originated, we know not how, in an inconceivably distant past. This stem we must assume to have been vegetative, and not animal, since it is the vegetable alone which is capable of assimilating inorganic matter, and of thus providing a starting point. Naturally, in tracing evolution backwards, the morphologist is immensely handicapped by having to deal with the very fragmentary and imperfect material which in the various strata of the earth's crust have been accidentally preserved. Such remains, however, scanty as they are, have afforded much evidence of gradual changes, and revealed innumerable links and gradations between the organic forms of one period and another, so that with many animals and some plants we have been able to trace back their ancestry to, at first sight, most unlikely sources. Thus the soled-hoofed horse has been proved to have descended from five-toed progenitors by an unbroken series of linking types showing the gradual disappearance of the separate toes as such. The morphologist, however, goes deeper than the mere outside. The term embraces many scientific branches, and the anatomist or osteologist among them who, analysing, as it were, the present horse's hoof and leg, will find rudiments still left of the suppressed toes. It is, however, another allied branch of science—that of the embryologist, or student of the first stages of reproduction—who has discovered, perhaps, the most striking morphological fact—viz., that all the higher animals, including man himself, passes through all the prior evolutional grades, and assumes seriatim the successive phases until at birth the immediate parental type is reached. In the plant, of course, few such successive phases can be noted; but here and there, as in the spiny gorse, where the pea relationship is disguised in the foliage by transformation of leaves into spines, though obvious enough in the flower, the first leaves produced by the seed show the relationship clearly; and the botanist can tell us of many other cases. No one ignorant of botany, and the morphological evidence it embraces, could credit that, despite the utter dissimilarity in most plants between the foliage and the flower, yet the latter is built up of modified leaves in all cases. Teratology is the term applied to that branch of morphology dealing with this phase of plant evolution, particularly in relation to reversions and other abnormalities, which often give the evolutional clue. In green roses and similar cases we see reversion to the floral type; and still more so in the many cases which crop up of leafy forms of stamens and stigmas, and transformations of very irregular forms of flowers, such as the antirrhinum and foxglove, into symmetrical corollas of what may be termed the standard type. Here it is beyond doubt that the extraordinary forms of flowers have been gradually evolved by response to some elective faculties on the part of the insect world, since the more attractive the flower the more convenient the access to the nectaries or pollen, the more likely was the plant so constituted to benefit by insectorial visits, and in this way constant progress resulted. Coincidently the insects themselves became modified, since those best able to obtain nutrition from the flowers possessed an advantage over less gifted ones; and so the law of survival of the fittest worked on both sides towards greater and greater morphological changes.

MR. HERBERT TATE.

Mr. Herbert Tate, whose portrait we have the pleasure of giving herewith, has done such excellent work as chief of the parks and open spaces of Halifax as to have greatly enhanced the rural amenities of this populous centre, and to have afforded conclusive evidence of his remarkable taste and judgment. Mr. Tate was appointed superintendent of the Halifax parks, recreation grounds, and cemetery in 1899, and was the first superintendent who had been appointed by the Parks Committee. At that time there were eight parks and recreation grounds, and one cemetery, and now there are twenty open spaces, these and the cemetery costing less than did the nine open spaces in 1899. The Halifax parks are practically flower gardens, and in the People's Park, which has an area of thirteen acres, 100,000 bedding plants are annually employed in beautifying the park during the summer months; and 20,000 bulbs, mostly tulips, are planted for the production of the spring display. In Scroggs Park, with an area of twenty-four acres, is embellished with 50,000 bedding plants during the summer months; and in Akroyd Park, of which the area is ten acres, some 40,000 plants are annually bedded out. Other parks are freely embellished with summer flowers, but these figures will suffice to show how large is the stock of plants annually raised for the production of summer displays of flowers and foliage. Halifax, as so well known, is a manufacturing town, and the smoke from the array of long chimneys has so destructive an effect on shrubs that it is not possible to keep evergreens, such as rhododendrons, aucubas, and hollies, in good condition for more than one season. To enable him to raise stocks of bedding plants under favourable conditions, and to grow on stocks of trees and shrubs for filling up blanks in the parks, Mr. Tate has established a nursery of two acres five miles distant from the town, and beyond the influence of the smoke, which, it need hardly be said, has proved a valuable adjunct. Mr. Tate has done good service in afforestation ; and four years since, when the Corporation found it necessary to provide work for the unemployed, he planted eighty acres of land on the moors with suitable trees, which are now making good progress.

Amateur Gardening Christmas Number. The issue of "Amateur Gardening" that is specially associated with the Christmas season is, as in previous years bright, interesting, and entertaining. A special feature of the 1911 issue is a fine art supplement, in which are numerous illustrations of flowers photographed in their natural colours, and reproduced by the three-colour process. These illustrations include borders of hardy flowers, bowers of rambling roses, rockeries, a pool of water-lilies, and beds of zonal pelargoniums and scarlet salvias, all remarkable for their interest and charm and as examples of high-class colour printing. There are also numerous illustrations in black and white. The contents are varied, interesting, and useful, and will be much appreciated by amateur gardeners.

National Rose Society.—The National Rose Society will hold its annual meeting at the Westminster Palace Hotel, Victoria Street, S.W., on Thursday next, at 3 p.m. The election of officers and members will proceed on somewhat different lines to those which have been followed in previous years. At the annual meeting in 1910 it was suggested by several of the members present that a change should be made in the method of procedure for the purpose of facilitating the addition of new members to the Council each year, and a promise was made that the matter should have attention. In accordance with this promise a special meeting of the members was held in the course of the summer, and new rules governing the election unanimously passed. Under these rules, all nominations to the various offices and membership of Council had to reach the hon. secretary not later than November 1, and all the names so received be entered on a list, and the list be sent out to the members and used by them as a balloting paper. It was further enacted that there should be two classes of vice-presidents—one, the honorary vice-presidents, to include those who had rendered good service in the cause of the rose, but for various reasons are unable to attend the Council meetings ; and the other the acting vice-presidents, to include those who are able to take part in the management of the society. We are pleased to observe that Mr .H. R. Darlington, Mr. E. J. Holland, and Dr. A. H. Williams are nominated as acting vice-presidents, for they have done such splendid service to the society as to fully deserve that honour. As the nominations are not in excess of the vacancies, it may be assumed that the members have not taken advantage of the greater opportunities they now have for effecting changes in the executive. The annual meeting will be followed at 4.30 p.m. by a conversazione, at which the Rev. J. H. Pemberton, president of the society, will give a short address, and there will be music.

The Gardeners' Company.—A short time since the Gardeners' Company presented a petition to the Court of Aldermen of the City of London in favour of an increase of forty in the number of Liverymen, and the latter body have agreed to the desired increase.

Wart Disease in Potatoes. A large number of cases of wart disease, or black scab, have been reported to the Board of Agriculture during the past season. In nearly every instance the outbreaks have occurred in districts in which the disease has been present for years, and the majority of cases are on allotments and in small gardens. Several places in which disease was recorded in previous years have been ascertained to be free from disease this year. The high temperature of the past summer does not appear to have had much, if any, effect in checking the disease, but it has in numerous instances appeared in a different form. The warty outgrowths which are characteristic of the attack have appeared in the stem and leaves, as well as on the tubers, and cases have been reported where the whole of the disease has appeared on the parts of the plants above the ground, while the tubers remained free. An illustration of a portion of the haulm affected by the fungus is given in the current issue of the "Journal" of the Board, and this has much the appearance of a leaf of a good type of Scotch kale.

Mutation in Œnothera.—To a recent meeting of the Linnean Society Dr. R. R. Gates contributed a paper in which he dealt with certain aspects of the mutation problem in Œnothera. At the outset he directed attention to the fact that work with the œnotheras has developed in several directions, and that a concerted attack upon the behaviour of the œnotheras in heredity and variation from several points of view gives a broader basis for the interpretation of the evolutionary significance of these phenomena than has hitherto been possible in most other genera. The cytological evidence has shown that in most of the mutants from Œnothera Lamarckiana the chromosome number is unchanged, but in the mutant Œ. gigas it is doubled. Hence mutants originate in various ways, and evidence goes to show that the chromosome doubling in Œ. gigas probably occurred either in the fertilised egg or in a megaspore mother-cell, which afterwards developed apogamously. On the other hand, in certain cases the mutational change probably occurred during the reduction divisions. Thus Œ. rubricalyx is a mutant from Œ. rubrinervis, which produces an extreme amount of pigment ; and when crossed with the parent type the new character behaves as a Mendelian dominant, and in such a way as to show that the original mutant individual was heterozygous, and probably originated from a cross between a germ-cell in which the new dominant character appeared, and one in which it was lacking. From this and much other evidence mutation in Œnothera appears to Dr. Gates to be due to a general condition of germinal instability, which in turn is probably connected with crossing in the ancestry. This, however, by no means deprives it of evolutionary significance, for all open-pollinated species of plants are hybrids in the sense that various races have participated in their immediate ancestry.

Staffs of Botanical Establishments.—A list of the staffs of the Royal Botanic Gardens, Kew, and of Botanical Departments, Establishments and Officers at home and in India and the Colonies in correspondence with Kew, has been issued as an appendix to the "Kew Bulletin." The list will be found useful to those who are desirous of corresponding with the botanical establishments in various departments of the British Empire, and also of much interest to those who make a point of keeping themselves informed as to the constitution of the several staffs.

Education of Small Holders.—In presenting prizes at the Cambridge County School, Mr. Rider Haggard referred to the importance of small holders being fully acquainted with the management of their holdings, and suggested that in Cambridgeshire there should be established an institution for the education of small holders, as nearly as possible on the model of that at Ringstead. In such an institution no one, male or female, should be admitted until they were at least sixteen years of age; personally he should prefer eighteen. There should be a summer and winter course of five or six months. The pupils should be asked to pay some sum in return for the great advantages which they would receive, but there should be no examination, a discretionary power being given to those in charge to ask any who were idle or worthless to retire. Small holders lacked knowledge, and he asked that they should be given the opportunity of acquiring knowledge, not by means of examinations, from which most of them would flee, but by means of the practical instruction of practical teachers, freely offered to those who wish to avail themselves thereof.

Mr. C. O. Farquharson, B.Sc., of the University of Aberdeen, has been appointed by the Secretary of State for the Colonies, on the recommendation of Kew, mycologist in Southern Nigeria.

Indian Species of Impatiens.—In the current issue of the "Kew Bulletin," Sir Joseph Hooker describes six Indian species of Impatiens, that were found by Mr. Meebold in the course of his visit to the Nilgiri Hills, Cochin, and Travancore. The specimens submitted to Sir Joseph Hooker consisted of twenty-one species under forty-four numbers, and of these six were quite new. Their names are Impatiens herbicola, I. rivulicoli, I. pallidiflora, I. macrocarpa, I. cochinica, and I. verecunda. The first three species, all from Travancore, differ from the widely distributed I. chinensis, chiefly in the remarkably small flowers, capsules, and seeds.

CHRYSANTHEMUM CONFERENCE.

The Chrysanthemum Conference arranged by the National Chrysanthemum Society was held at Carr's Restaurant at 7 o'clock on Monday evening, December 4. Sir Albert Rollit being unable to be present owing to indisposition, the chair was taken by Mr. Thos. Bevan.

The attendance was excellent, over a hundred chrysanthemum growers, amateur and professional, being present. The room was capitally decorated by large vases of fine chrysanthemum flowers brought by Mr. Cragg to illustrate his lecture.

In our present issue we give the lecture delivered by Mr. Percy Cragg, of Heston, Hounslow, on "Soil Preparation," reserving Mr. Ladds' lecture for our next issue.

Soil Preparation for Chrysanthemums in Pots.

In placing before you this evening the conclusions arrived at as results of our experiments and observations in soil preparation as applied to chrysanthemums grown in pots, I am not claiming that my firm has originated entirely fresh ideas on the subject, but rather that an attempt has been made to replace the rule of thumb method by one more up-to-date and scientific, and on a larger scale than has perhaps hitherto been attempted.

During one wet season we found that our chrysanthemums had been considerably overfed with compound manures; an error very easily committed through carelessness or bad judgment, when 30,000-40,000 pots are grown. That meant a loss on the quality of the bloom, loss of the manure given, and the cost of the labour for applying it. To prevent a recurrence of this loss, which might easily be serious, we decided to try other methods of feeding. An obvious alternative was to enrich the soil. We therefore consulted a horticultural chemist, and, acting on his advice, decided to mix with the soil the greater portion of our chemical manures, and so put them into the soil in such forms as would give us a regular succession of foods suitable for the plants during the period of their growth.

Our first difficulty after this decision was arrived at was to know exactly how rich the compost should be. Ultimately we decided on the following analysis, or, rather, part analysis, for our working basis. It is the analysis of a good rich soil, which shows the following percentage of the four chief necessaries for plant life: Phosphoric acid .5, potash .25, nitrogen .45, lime .2. We did not think it necessary to worry about any other ingredients, as most of them are present in the majority of soils in sufficient quantities. Magnesia may have to be taken into account with some soils, but our soil contains plenty; and further, our water is magnesia hard.

Having settled on what seemed most adapted for our purpose, we proceeded to carry theory into practice. The portion of a field selected for the next season's crop was stripped, and to it was added one part of mushroom manure to six of soil. The whole was thoroughly mixed, and samples were then drawn from different parts of the heap; these were again mixed, and then a portion was sent to the analyst. His report showed the soil to be considerably poorer than we desired it to be. Sufficient potash was present, but the quantity of phosphoric acid, nitrogen, and lime was undoubtedly insufficient. The manures we decided to use eventually were as follows: Basic slag, containing lime and phosphates; bone-meal, containing nitrogen and phosphates; ground hoof, for nitrogen only; and ordinary gray burnt lime. The basic slag was the 38 per cent. brand passing through a sieve 10,000 meshes to the inch; the bone-meal showed 4.5 nitrogen and 45 phosphates, and was of ⅛in. grist; the hoof was also of ⅛in. grist, and showed 15 of nitrogen; while the lime was ordinary builder's gray lime, and showed 77 per cent. purity. We obtained by these manures nitrogen and phosphates of various degrees of solubility. As the nitrogen of the soil and mushroom manure were exhausted, that from the bone-meal would be available, and finally the hoof would give up its portion. For phosphates the order of solubility would be, first the soil and mushroom manure, then the bone-meal, and lastly the basic slag.

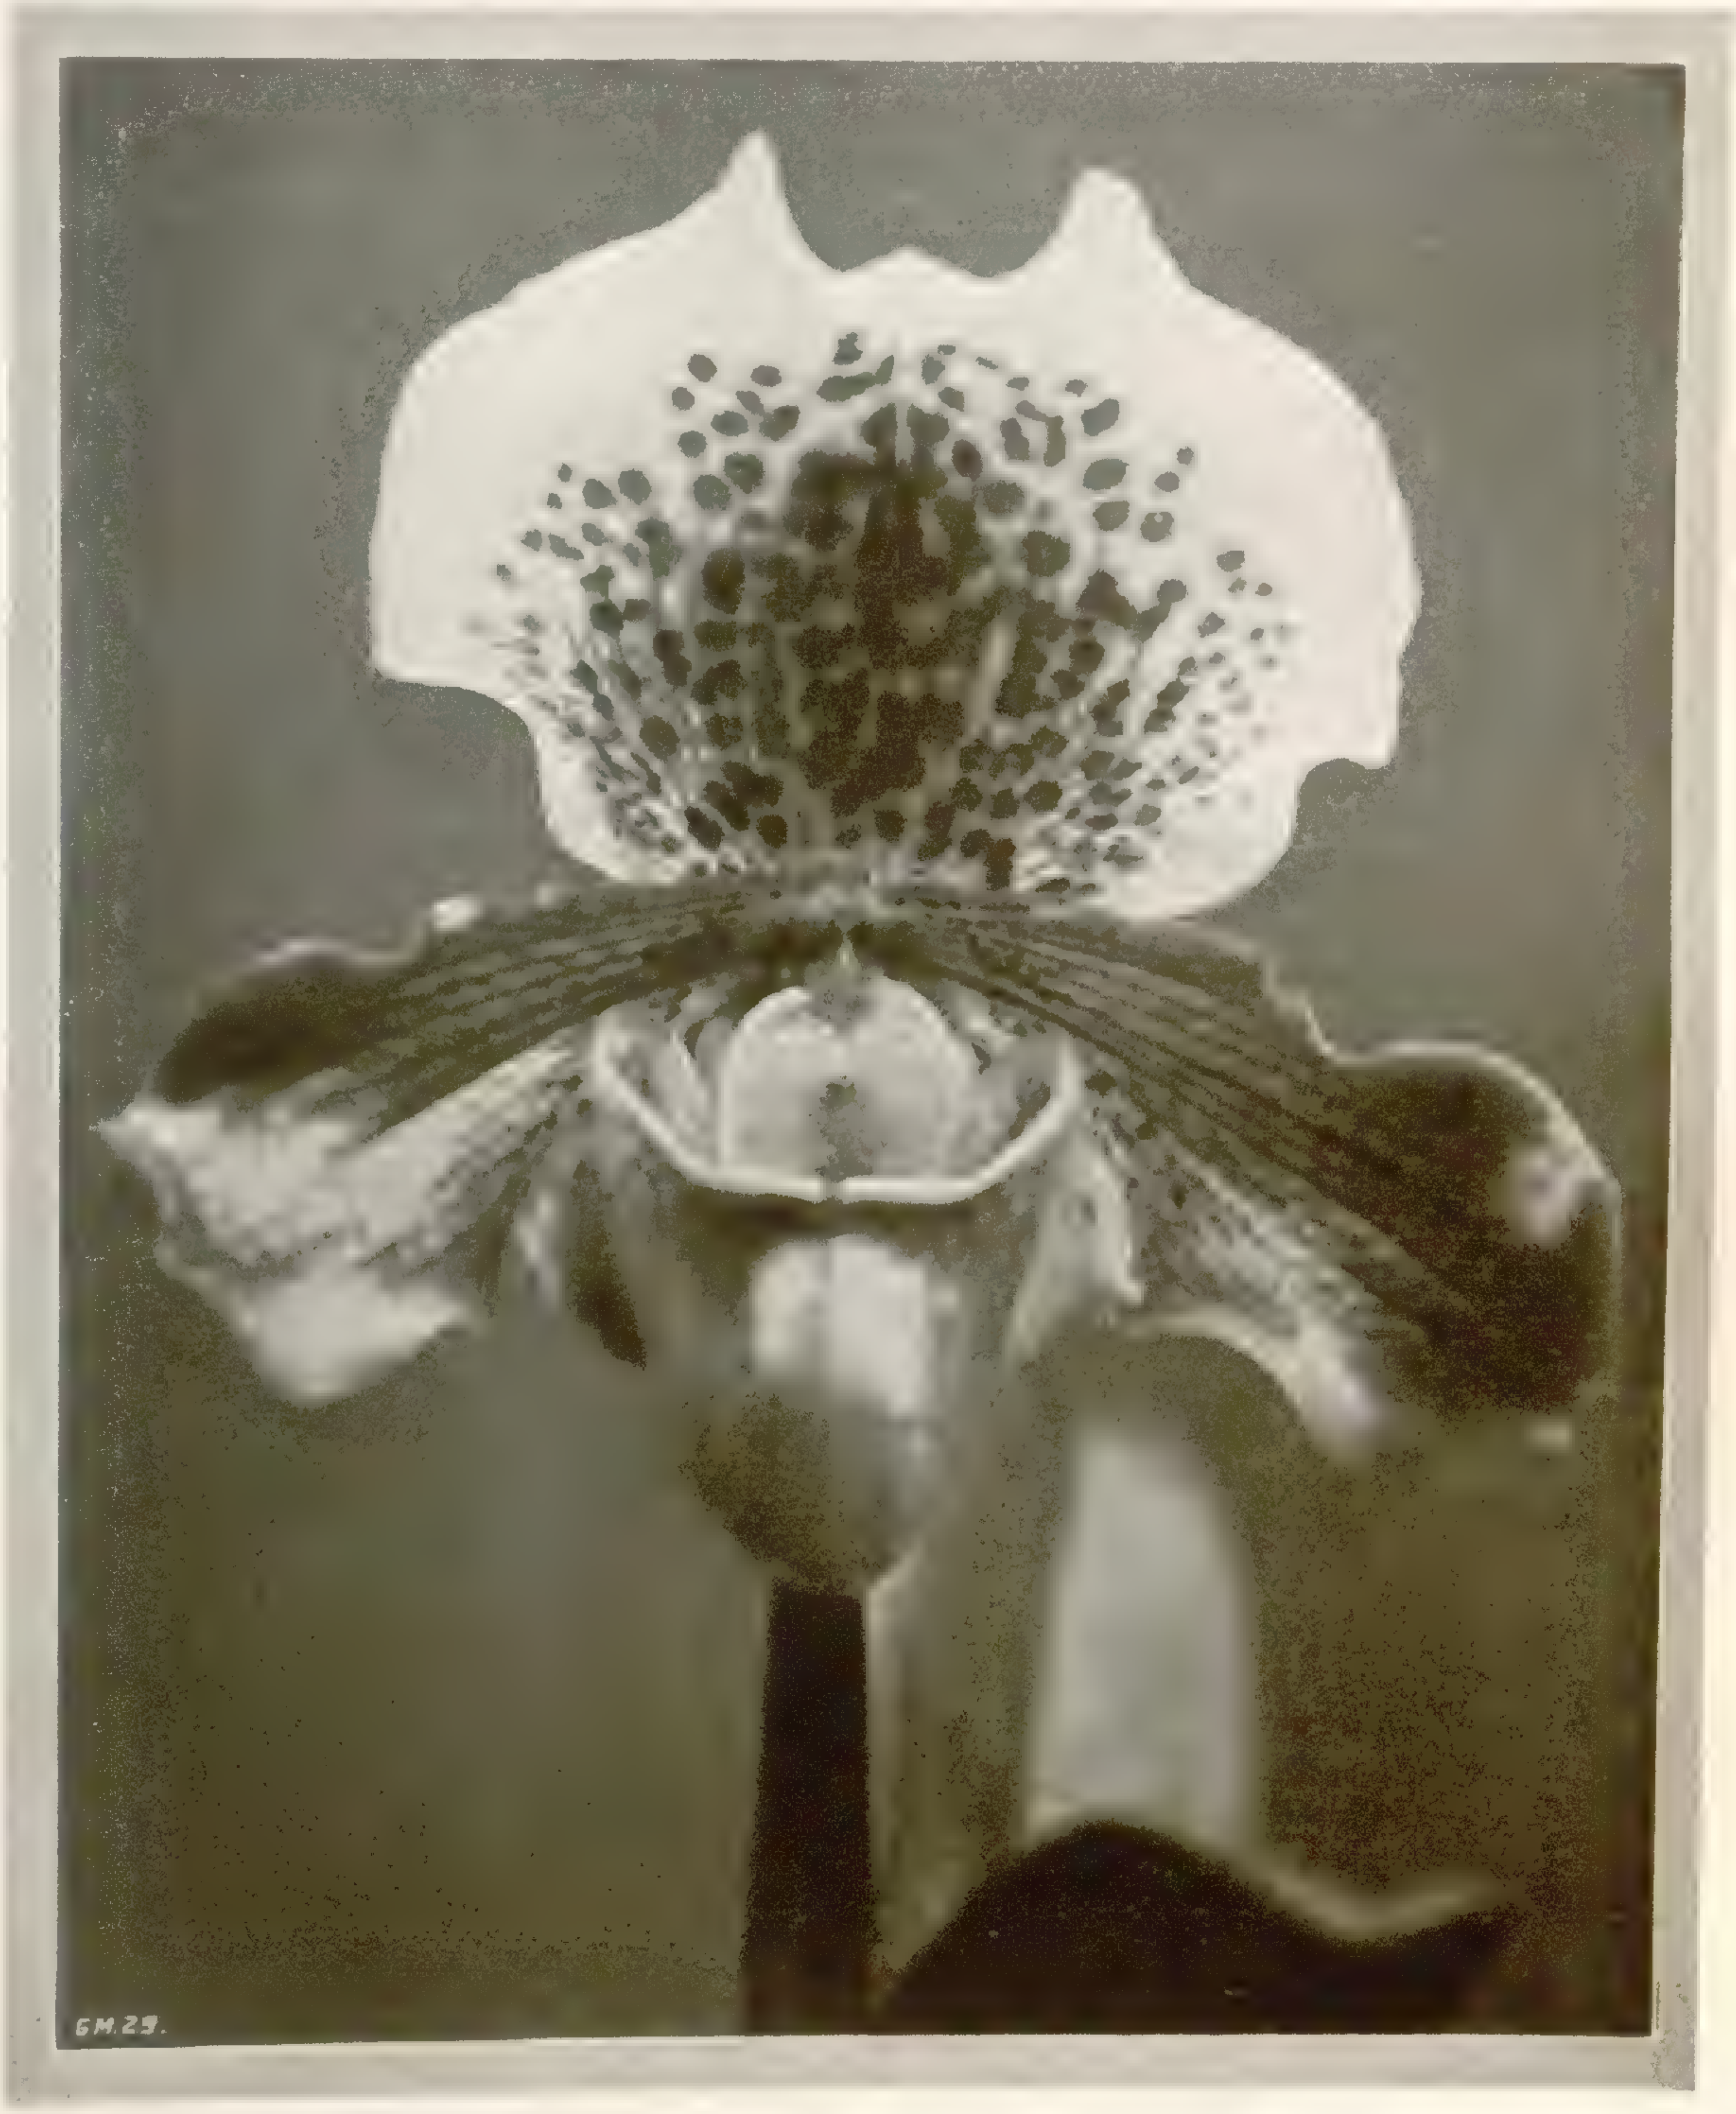
Our soil is alluvial, and is like most soils of that nature, deficient in lime. The majority of our analyses showed less than 1.0 of lime. We have been content to raise this to about 2., using 1½ tons of lime 77 per cent. purity to 100 tons of soil. To use more at a time would probably cause heating, and a portion of the nitrogen contained in the chemicals would be lost. Lime is very easily added during the growing season if required, by merely dusting the surface of the pots with it.

I have mentioned that we did not take potash into account, as we thought that the analysis showed it to be present in sufficient quantity. Further experience has caused us to reconsider this decision. Having constantly to battle against fungoid diseases, we came to the conclusion that something was lacking in our treatment. We found that where we used extra potash for tomatoes, we had less mildew, the deduction being that although potash was present in fair quantity, it could not be readily available. For our next year's crop, therefore, we shall add potash manures, and shall try to raise the percentage to .35. Kainit, and all the ashes from wood and refuse fires, will be applied to the field as a surface dressing, and sulphate of potash will be mixed with the soil at the final turning.

Mr. A. D. Hall, of Rothamstead, says there is abundant proof to show that potash makes plants more resistant to fungoid diseases. That is a hint worth following by those growers who suffer from rust. Potash also appears to delay maturity—another useful hint for a dry season. Last season we added soot to our compost, ten bags being mixed with 100 yards of soil. The result has proved beneficial both in colour and foliage. For the coming season we shall increase the soot to fifteen bags per hundred yards of soil.

The following are the particulars of the ingredients mixed with the soil for the 1911 crop: To each 100 cubic yards of soil (we take 1 yard to be equivalent to 1 ton as the soil is stacked), we added 1½ tons of lime (77 per cent. purity), ½ ton of basic slag (38 per cent.), ¾ ton bone-meal (4.5 N., 45.0 P.), 12 cwt. ground hoof (15.0 N.), and 10 bags of soot. This added to our original analysis gave the following percentages: Lime 2, nitrogen .417, phosphate .615, potash .32. The approximate cost per 100 yards was £15 for the manures and soot, excluding mushroom manure.

Such is, roughly outlined, the system we work upon, and since adopting it we have found an all-round improvement in the size.



CYPRIPEDIUM DRACO.

A very large and handsome hybrid, with white, green, and brownish colouring, and purple spots. The illustration shows the flower slightly reduced. A.M., R.H.S., December 5. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester.

lasting qualities, and the colour of our blooms. All soils will not respond to the same treatment, but the root idea will be found to be the same, viz., to raise the percentages of the different elements necessary to plant life until a well-balanced compost is obtained; and, further, to have them present in such forms that a constant succession of complete food is available.

Soils that have already present a fair proportion of lime, would probably take superphosphate better than basic slag. For those that are rich in nitrogen steamed bone flour would be more economical than bonemeal. I would advise that hoof be used if possible because of its lasting qualities. The size of the grist of the bonemeal and hoof is a factor of great importance when the rate of solubility is considered. Now that hoof is so dear and is difficult to obtain a larger grist of bonemeal might be made to take its place, using, perhaps, ⅛in. and ⅜in. grist together. Ground chalk would probably be more beneficial on light dry soils, or with those that already have a fair percentage of lime. On our rather heavy soil the amount of chalk that would be necessary would have a bad mechanical effect. These are, of course, questions that would have to be discussed with a competent horticultural chemist by those who have not the necessary knowledge of horticultural chemistry.

Before leaving this part of my paper, I would emphasise the necessity for great care in the mixing, if manures in quantity are used. Lime in all cases ought to be put on the ground in the autumn, and allowed to lie for a month or two in order to become well slaked by the atmosphere. The soil should be stacked for three months, mixing in the chemicals just before the compost is required. Two or three turns are required to ensure equal distribution. It is preferable to have the soil in small heaps, rather than in one large one, to allow the air to circulate through the heaps, and to minimise the risk of heating.

In ordinary seasons we have found weak feeds of stable liquid and of soot water, with an occasional feed of compound manure mixed with a large bulk of soil, quite sufficient to carry the blooms to perfection. A season like 1911, however, upsets calculations considerably, owing to the enormous quantities of water required by the plants, and consequent loss by drainage from the soil.

The method I have outlined in reality denotes only the one stage commencement for those who wish to work on scientific and economical lines. As the soil is the starting point of all our work, the pasture should be taken in hand some years before it is required. Nitrogen is the dearest food we have to buy, but it can be obtained at a trifling cost from the atmosphere by the aid of leguminous plants. Our mode of procedure is as follows. We have a field of about four acres of turf, which we hope to make last for the next 25 years. It is stripped in sections to a depth of about 6in. The stripped portion is then dug about 2ft. deep, plenty of mushroom manure worked in, rolled down firmly, and sown with a mixture of seeds containing a fair proportion of deep-rooting grasses and of clover. Lime, basic slag, and, perhaps, potash are to be applied in yearly dressings.

We hope to have formed a turf richer in all essentials than the original in from five to six years. Then the process will be repeated as turf is wanted. Having a light brick earth to work on we estimate to lower in time the original level by 2ft., and still leave a decent turf.

The work of seeding is expensive, but the increased crops of hay or green feed will often repay the cost. We obtained in 1910 five cuts of grass from a piece sown that year, and three even in a dry season like the past.

Light sowings of clover, together with dressings of a complete manure, will improve a poor pasture out of recognition. A. D. Hall makes a point of the increase of clovers and other leguminous plants as the result of dressings of manures containing potash. He gives an instance where leguminous plants increased from 20 per cent. to 50 per cent. as the result of complete feeding. Before I close there are one or two manures we use, in addition to those already mentioned, that I should like to speak about.

I have said that lime may be sprinkled on the tops of the pots during the growing season. Its effect is often magical. Its action is to render the insoluble forms of food available. On one occasion we used plain soil and a sprinkling of lime as a top-dressing, and the plants shot up at such a rate that they had to be checked by a stiff dose of superphosphate. Superphosphate we use largely in quantities of ¼ to ½oz. per 10-inch pot, mixed with three times its bulk of soil. Its action is to stiffen the stems, check the growth of the foliage, and improve the colour of the blooms. Nitrate of potash and phosphate of potash are expensive manures to buy, but prove fairly cheap to use. Mixed together in equal quantities, and used at the rate of ½oz. to 1oz. per gallon of water, they form a complete food. By altering the mixture either nitrogen or phosphate may be increased or decreased.

The last item I have to talk about is sulphate of iron. We find chrysanthemums, especially some varieties, in cold, wet seasons, are apt to turn a bit yellow, the uncongenial conditions upset them; they, in fact, suffer from what may be termed anæmia, and require iron. A dose of sulphate of iron, ½oz. to the gallon, will quickly restore a healthy colour to the foliage. It should be mixed in wooden vessels, and be applied from well-painted cans.

I think I have laid before you the main principles we apply in our nurseries, and I hope I have been successful in presenting them clearly. My aim has been to put before you concisely what little knowledge we have acquired of a difficult subject. I would advise those who wish to adopt the same methods to go into the matter thoroughly and carefully under competent advice. The methods outlined are, of course, as useful for other crops as they are for chrysanthemums. I have necessarily only been able to touch my subject very slightly in the time at my disposal; it really requires hours to do it justice. If I have not made myself clear, I offer you my apologies, and can only say that I shall be only too pleased to answer any questions as far as I am able.

Mr. Norman Davis spoke very highly of Mr. Cragg's lecture, and again emphasised the great value of sulphate of potash in correcting many evils to which plant life is prone. He urged that lime should be used with great care, and said that it would force flowers into usefulness quickly, but such flowers would not have great lasting properties. Sulphate of iron had the effect, he said, of quickly liberating plant foods in the soil, and its use should be followed by liberal feeding. Mr. Godber, Bedford, said he found sulphate of potash more useful than kainit, and he preferred chalk to free lime in mixing compost for chrysanthemums. Mr. Cragg said that well-slaked lime should be used, and not fresh lime, which was caustic; lime was itself of no use to plants, but was the key to unlock the nitrogen, potash and phosphates in the compost.

Mr. Godfrey pointed out that sulphate of ammonia, formerly used so largely in chrysanthemum growing, was now seldom used, and nitrate of soda was used in the production of dwarf plants in small pots, given twice a year. Several speakers said that sulphate of ammonia was far too forcing a manure for chrysanthemums.

In conclusion, Mr. Cragg strongly emphasised the need of analysis to begin with, adding manures under competent advice, and then progressing as experience was gained, but on scientific principles.

Very hearty votes of thanks were accorded to Mr. Ladds and Mr. Cragg, moved by the Chairman, and ably seconded by Mr. W. J. Godfrey, and supported by Mr. D. B. Crane. The lecturers suitably responded, and the meeting closed about nine o'clock with votes of thanks to the chairman and secretary. Altogether this was a capital conference, and should lead to others.

NEW PLANTS, ETC.

CHRYSANTHEMUMS.

Edith Mileham. — A very showy single variety of fine form and substance. The colour is very deep and rich rosy pink, with a well-defined narrow white zone around the disk. Commendation, N.C.S., December 4. Mr. G. Mileham, Emlyn Park Gardens, Leatherhead.

Isabel Gray.—A single variety of great distinctness, and of fair size and good substance. The colour is very difficult to describe, but pale crushed strawberry, shaded with buff about fits it. F.C.C., N.C.S., December 4. Mr. Phillip Ladds, Swanley Gardens.

Golden Cullingfordi.—A charming decorative variety of rich golden-yellow, capital for sprays, and quite elegant. It is a counterpart of the old crimson Cullingfordi in all save colour. Commendation, N.C.S., December 4. Mr. G. Prickett, Enfield Highway.

Mrs. David Symes.—A very fine Japanese decorative variety, of charming form, and extremely graceful. It is of the purest possible white, and quite glistening. F.C.C., N.C.S., December 4. Messrs. W. Wells and Co., Merstham.

Mrs. Harry Turner.—This handsome decorative Japanese variety gives large blooms of excellent substance, and on long stout stems. The colour is vividly rich velvety crimson, grand under artificial light. F.C.C., N.C.S., December 4. Messrs. W. Wells and Co., Merstham.

Ada Brooker. — A handsome decorative variety of loosely incurving form; the flowers are of good size, deep chestnut-red with bronze reverse. Commendation, N.C.S., December 4. Messrs. W. Wells and Co., Merstham.

Ruby Beauty.—A grand variety with splendid colour. It is a big Japanese single of brilliant rich ruby-red colouring, with dark yellow centre. Commendation, N.C.S., December 4. Messrs. W. Wells and Co., Merstham.

Pentas carnea.—It is just about 70 years since this pretty, free-flowering subject was introduced from tropical Africa, and a generation ago it was, I think, more popular than it is to-day. It is of rather soft growth, being, in fact, what is usually referred to as a sub-shrub, while the leaves and stems are hairy. The blossoms, which are borne in neat rounded clusters, are of a pretty pink tint, and freely borne over a lengthened period. As it is of easy culture, this pentas might well have more consideration paid it as it is very pretty. A deeper coloured species, Pentas kermesina, is rather less vigorous than the other, and is not so frequently met with.—W. T.

Hibiscus rosea sinensis.—This tropical shrub represented in our gardens by many varieties would appear to have found the last summer to its liking, for indoors and out it bloomed with unwonted freedom. In sub-tropical gardening large specimens are often used, disposed, either in some of the mixed beds, or sunk singly in the turf. In this way the typical crimson, single-flowered form is as good as any, but still there is a wide range of colour both amongst single and double varieties. As a rule, Hibiscus rosea sinensis does not bloom freely in a small state, but some forms have been more than once seen blooming most profusely in the shape of small, bushy specimens. One in particular, Hibiscus sub-violaceus, with double flowers of a deep violet-rose colour, was unusually showy. Being of free growth, many of the varieties are seen to considerable advantage when trained to the sides or end of a lofty greenhouse or conservatory. Apart from this, they may be grown as bushes in large pots or tubs, and stood outside during the summer months. These hibiscuses are readily propagated by cuttings, and the young plants quickly attain an effective size.—W.

AN AMATEUR'S VINERY.

As an amateur I have grown Black Hamburgh grapes for quite twenty years, but did not exhibit until 1905, when I won a modest third prize at Norwich. My next venture in the show room was in 1908, and I then obtained a first prize, in 1909 and also in 1910 I secured second prize, but this year was once more successful in securing the premier award for three bunches of Black Hamburghs. I enclose a photograph of the interior of my vinery, and though this represents the crop in 1905, it gives an excellent idea of the general appearance of my little vinery every fruiting season. The house is 22ft. by 11ft., and the crop is usually about 150 bunches. Large, strong, healthy leaves have always been a feature, some of them measuring a foot across.

The vinery is an entirely cold one, and after a fairly early date in December it is left open as fully as possible until the time comes round for restarting the vines—about Lady Day. Doubtless you will not be surprised to hear that I have read the Gardeners' Magazine regularly for many years, and have gathered much valuable information concerning grape culture from its pages.

J. M. Fitzpatrick.

Dereham Road, Norwich.

A FINE CROP OF BLACK HAMBURGH GRAPES.

This illustration represents an entirely unheated vinery, wherein Mr. J. M. Fitzpatrick, Norwich, annually produces about 150 bunches, some of which secured high honours in keen competition at the Norwich Autumn Show.

AMERICAN PERPETUAL CARNATION NOVELTIES.

It is still too early in the present season to definitely decide upon the merits and shortcomings of the perpetual carnation novelties. Yet the season is sufficiently advanced for a really good variety to have proved its merits, and a really bad one to have exhibited its failings.

Taking the new varieties disseminated by the American raisers last season, it is safe to say that White Wonder is head and shoulders over all others. This I predicted in the Gardeners' Magazine last spring. That, however, was hardly a prophecy, because at the time of writing my brother had some plants, which he had received in advance for trial, flowering at Haywards Heath, and we could see then that White Wonder was the finest white perpetual carnation in the world. Pure in colour, rich in perfume, its large shapely flower is carried in a stately manner on long and erect stems of a free vigorous growth. This variety has yet to develop a fault.

Gloriosa comes second, in point of merit. In this we have that delightful shade of true pink, devoid of any magenta shade, which was found in that grand old variety Floriana. For that charm alone Floriana lived on with many far beyond its allotted span, and after all other varieties had surpassed it in productiveness. Not until the advent of Gloriosa did a pink variety replace Floriana in colour. The habit of growth is rather thin, but very quick. Every growth produces a flower. The stem and calyx are always strong and reliable. The flower itself is large, with good outer petals, and heavily fringed. Gloriosa will undoubtedly become very popular, and, from a grower's point of view, should have been recognised by the R.H.S., but this may come later.

Washington was boomed in America as a Lawson-coloured sport of Enchantress, but the man who described it as such had certainly his share of imaginative power, or perhaps he wished it to be what he said it was. However, Washington is quite good over here, and we must make allowances for difference of climate. It is in the way of Rose Pink Enchantress (or Dorothy Gordon, which is practically synonymous) in colour, but it has a cerise shade when the flower is young. The flower is also deeper in colour, and it will, I believe, supplant, Rose Pink Enchantress.

White House we all have seen and heard much about. Its large massive flowers and healthy foliage are attractive, but its slowness of growth, which compels you to wait rather long for the flowers, is its weakness.

Bright Spot, a cerise pink of the old Aristocrat shade, is prone to disease. It is undersized, and inferior to many varieties of a similar colour which have preceded it. Bonfire is certainly bright, but not superior to Scarlet Glow in this respect. Princess Charming was supposed by its raisers to be superior to Enchantress, but unless the Princess proves to be more charming we shall certainly continue to be enchanted with Enchantress.

Montagu C. Allwood.

Everyone interested in a garden should obtain a copy of the Alphabet of Gardening by T. W. Sanders. Thoroughly practical information is given as to soils, manures, seed sowing, planting, potting, budding, pruning, grafting, forcing, hybridising, etc., with explanatory diagrams. Price, bound in cloth, 1s. 6d. net, post 1s. 9d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

ORNAMENTAL GRASSES.

To the three good ornamental grasses mentioned by one of your correspondents in the issue for September 2, may be added several which are worthy of more general cultivation.

Sorghum halepense, although a native of sub-tropical regions, is perfectly hardy, and forms a fine clump in a year or two if planted in good garden soil. The leaves are long and an inch broad, with a silvery white midrib. It grows anything from four feet to eight feet in height (according to the quality of the soil), the plumose flower heads being of a reddish-purple colour, and in strong plants, over a foot in length. Spartina polystachya var. aurea-marginata is a very graceful subject, either for the herbaceous border or the waterside. This, when well established, grows to a height of four or five feet, producing long, narrow, gracefully arched leaves which are lined with yellow.

AIRA CÆSPITOSA.

A graceful and highly ornamental grass; perfectly hardy, and well suited for culture in the border or by the water side.

The miscanthus (eulalia) are all very ornamental, especially the variety of M. japonicus, known as zebrinus, with its transverse bands of yellow, an inch or two wide. Aira cæspitosa (Deschampsia) is one of our prettiest native grasses; it delights in a damp situation, but is quite a success in an ordinary border, where, in a year or two, it forms a huge tuft of very narrow deep green leaves, which, with the silvery-grey plumes rising to four feet, forms a very pleasing object, the flower heads being very useful for cutting.

Erianthus Ravennæ is another desirable grass, forming a stately clump from three to six feet high, terminated by spreading panicles of reddish-tinted flower heads. The stipas are fairly ornamental, the two which appeal to me most being S. gigantea, which grows three feet high, and the fairly well known Feather Grass (S. pennata), which grows to about two feet, with its long, whitish, bearded plumes, which are said by Gerarde to have been used by ladies as feathers. Phalaris arundinacea, with its variegated form known as Ribbon Grass, so much favoured by cottagers, may be put to good account, along with those plants which are more generally used as edgings, etc., to flower beds, rather than as isolated specimens.

If one includes the annual and biennial grasses which are useful, the list becomes a long one, a select half dozen might include Bromus brizæformis, Panicum capillare, Lagurus ovatus, Holcus mollis, and Aira caryophyllea. With the forms of Pampas grass and the bamboos these grasses are of great value from an ornamental standpoint. One of our native sedges is well worth mention here, namely, Carex pendula. It is one of the largest, but is not liable to spread beyond reasonable limits, being more tufted than most species. The flower spikes reach a height of three feet or more, and then gracefully arch over owing to the weight of the long catkinlike flower heads.

Merton, Surrey. E. J. Allard.

SANDY SOILS.

The advantages of a sandy soil in a wet season such as 1909 are known to everyone with any experience in working them, and in the normal spring they are equally to be desired as it enables one to sow seeds and put out plants earlier, while, owing to the lessened water contact, the soil is warmer than a heavy one, and things come on more quickly. The drawbacks of such a soil in a dry summer like 1911 are fresh enough in the minds of those who had to deal with them. The aim of a gardener should be to make a light soil heavier and a heavy one lighter, or, to speak more correctly, the one more retentive of moisture and the other more porous, as well as less tenacious.

Vegetable matter in various stages of decomposition is a great absorbent of water, and it is the relative lack of this in sandy soils, as much as their coarseness of texture, which causes them to have so little water-holding power. Humus can absorb two or three times its weight of water, while sand can only hold about a quarter. This same porosity of soil which lets water run through so quickly also lets air into it very easily, and so hastens the breaking down of vegetable and animal matter into humus. This—the intermediate stage in the reduction of organic matter into its simple elements of water, carbonic acid, ammonia, and ash—is, in its pure form, a rather greasy or waxy substance, which coats the fine particles of soil, and so assists the retention of moisture, and in clay soils, it remains in this condition a long time instead of being rapidly oxidized as in those of a sandy character.

The principal thing to do, then, is to accumulate as much organic matter in the soil as possible. Liberal and persistent additions of animal manure constitute the usual method of bringing this about, but it is so expensive by itself that it is well to supplement it when we can. The garden bonfire should not be made the opportunity of waste it so often is, and, as a general rule, nothing should be burned that will decay within a moderate time, unless diseased in any way. When a piece of ground is trenched in the autumn, as much garden rubbish should be buried in the trench as can be conveniently disposed of in this way, bearing in mind the crop which is to follow. A good deal more can be disposed of by burying it in the annual heap of leaves, when, if the whole heap is turned in the winter or early in spring, most of it will be reduced to a crumbling mass by the autumn following. For the kitchen refuse a hole should be dug in some convenient spot into which it can be thrown, a little earth being sprinkled over it occasionally to keep it from becoming offensive. This may be dug out after a year, when it will have become excellent material for enriching the soil and increasing its water-holding capacity.

With the same object in view green-manuring should be practised whenever possible—that is, catch crops should be grown solely for the purpose of being dug in to improve the condition of the soil. No piece of ground should be left vacant in August and September, but, if nothing else can be done with it, something should be sown upon it, say, mustard, cress, or vetches, and the growth turned in during the winter or early in spring, when it will add to the store of humus in the soil, while its nitrogenous content has been obtained from nitrates which would in all probability have been washed out of the soil by the winter rains, and, in the case of leguminous plants, from the nitrogen of the air as well.

Very light soils are often poor in lime in a state of nature, and, even when not so, tend to become rapidly so under the high manuring practice of gardeners owing to the rapid oxidation of organic material, the acids of which dissolve out the chalk so that it is lost in the drainage water. When this is the case, chalk, not lime, should be applied, chalk making soil sticky, and therefore less porous, this being the very opposite to the effect of lime upon clay. Everyone must have observed the stickiness of a chalky road or footpath in wet weather. It should be spread on the soil in as fine condition as possible, and dug in straight away before all the fine particles are dissolved by the rain and washed away. The finer the condition in which the chalk is applied the better, forty pounds to forty square yards being a fair dressing. Wood ashes have a similar effect upon the physical condition of the soil.

Lastly, the method of cultivation of the soil has a great deal to do with its water-holding capacity. If it is dug in the autumn, and then simply raked over and sown in the spring, the water channels formed during the winter will let the maximum amount of the spring rains run through into the subsoil; but if it is dry in the spring the broken-up channels impede the drainage, with the result that the soil stores up more water for the summer. The hoeing of the surface should go on all through the dry months, or at least after every rain, to lessen the loss from the surface by conduction from below.

Alger Petts.

POINSETTIAS.

These effective winter subjects are not loosing their popularity, but are still probably the most showy plants we have for winter decorations. When kept in an intermediate temperature they remain quite fresh for a number of weeks, and for associating with chrysanthemums or other white flowers in the conservatory they are very telling. Used in a cut state, unfortunately, they do not remain fresh for such a long period, but if their stems are inserted in quite hot water for a few minutes when first cut it has the effect of preventing their flagging for some time. Poinsettias are very appropriate when used for the decoration of the dinner table at Christmas time, and holly placed on the cloth beneath them helps to complete a very seasonable arrangement.

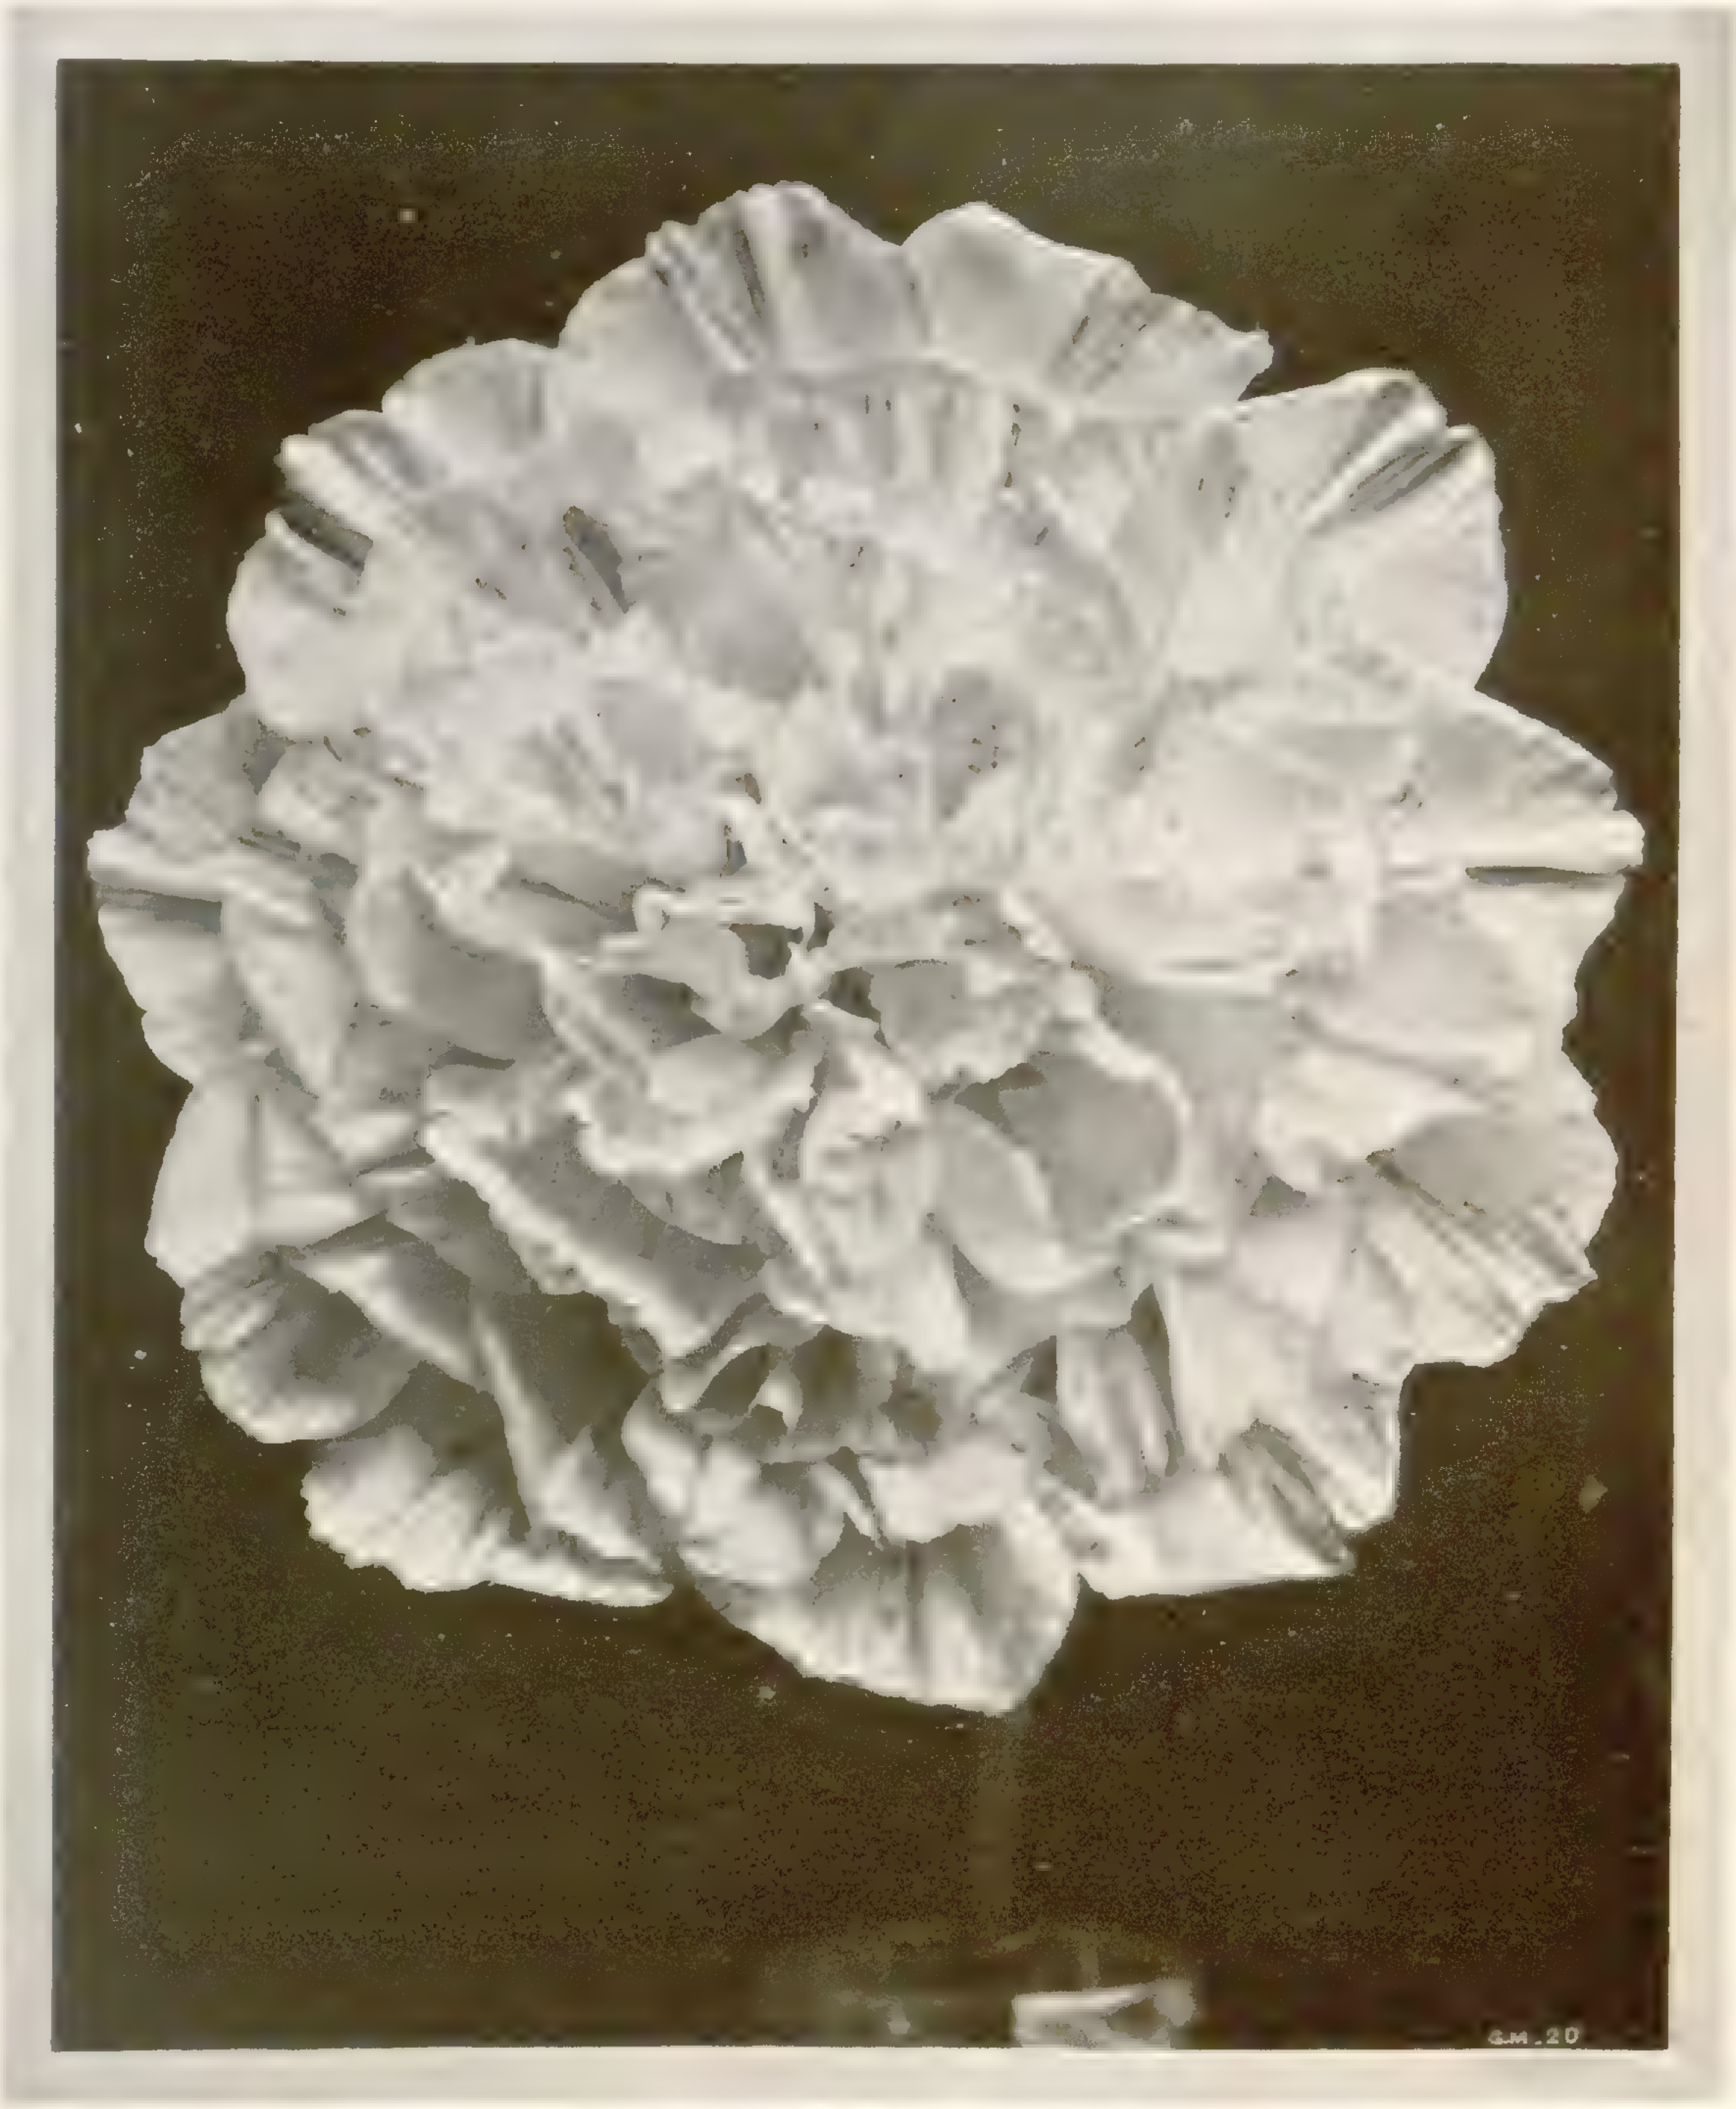
The cultivation of poinsettias presents few difficulties, but there are several points that it is important to pay attention to if one is to obtain the best results. Raised from cuttings inserted in spring, singly, in small pots, they should be grown in a house with a temperature of not less than 65 degrees, until established in six-inch pots, when they must be gradually accustomed to cooler conditions, finally placing them in a brick pit or frame for the summer months, and keeping them as near the glass as possible to prevent their becoming drawn. Give light shade from bright sunshine, but as the season advances gradually innure them to more sun, and remove them to a house with a temperature of 60 degrees early in September.

During the growing season regular applications of soot water are desirable, and when the pots are full of roots a little of some approved fertiliser can be given with advantage. I have found that Bentley's Carnation Manure suits poinsettias admirably, and develops that rich green foliage gardeners so love to see. As the bracts develop water must be given with especial care, and feeding be gradually discontinued. Carelessness in this direction soon results in loss of foliage, and a consequent diminution of the value of the plants.

J. Gardner.

A NEW BREAK IN WINTER-FLOWERING BEGONIAS.

The introduction of B. socotrana in the eighties of last century was taken advantage of by the hybridist, and numerous varieties have since then been raised therefrom. Of hybrids between Begonia socotrana and the tuberous-rooted section the first was John Heal, which flowered in 1883. According to "Hortus Veitchi" only a single plant of this particular cross was obtained, and from that all those now in cultivation were derived. This variety was distributed in 1885. After the advent of John Heal a number of other varieties were raised, some with single, and others with semi-double blossoms, many of which are now exceedingly popular. Practically all of these have flowers of a carmine, scarlet, or rosy-carmine tint. It was, therefore, somewhat of a surprise, at the meeting of the Royal Horticultural Society, on November 7, to see three distinct varieties shown by Messrs. J. Veitch and Son. These varieties were obtained by the intercrossing of B. socotrana with a yellow-flowered variety of the tuberous-rooted class. This latter colour was present to a greater or lesser extent in the flowers of each of those shown, while in addition the plants differed from the socotrana hybrids already in cultivation by their branching, sturdy habit, and particularly in the large size of the flowers. In this respect they were the equal of a good tuberous-rooted kind. The general appearance of the plants is well shown in the Gardeners' Magazine for November 11, where, on page 833, the variety Exquisite is depicted. The three varieties shown were Acquisition, pink, with an orange suffusion; Exquisite, deep pink, shaded with carmine towards the edges of the petals, and the centre of the flower lit up with orange; Her Majesty, warm orange, with a reddish tinge, especially at the edges. Such subtle tints are difficult to describe, and it is rare to find two who see eye to eye in such matters. There can, however, be no difference of opinion that these distinct and beautiful varieties are a decided acquisition for winter decorations.

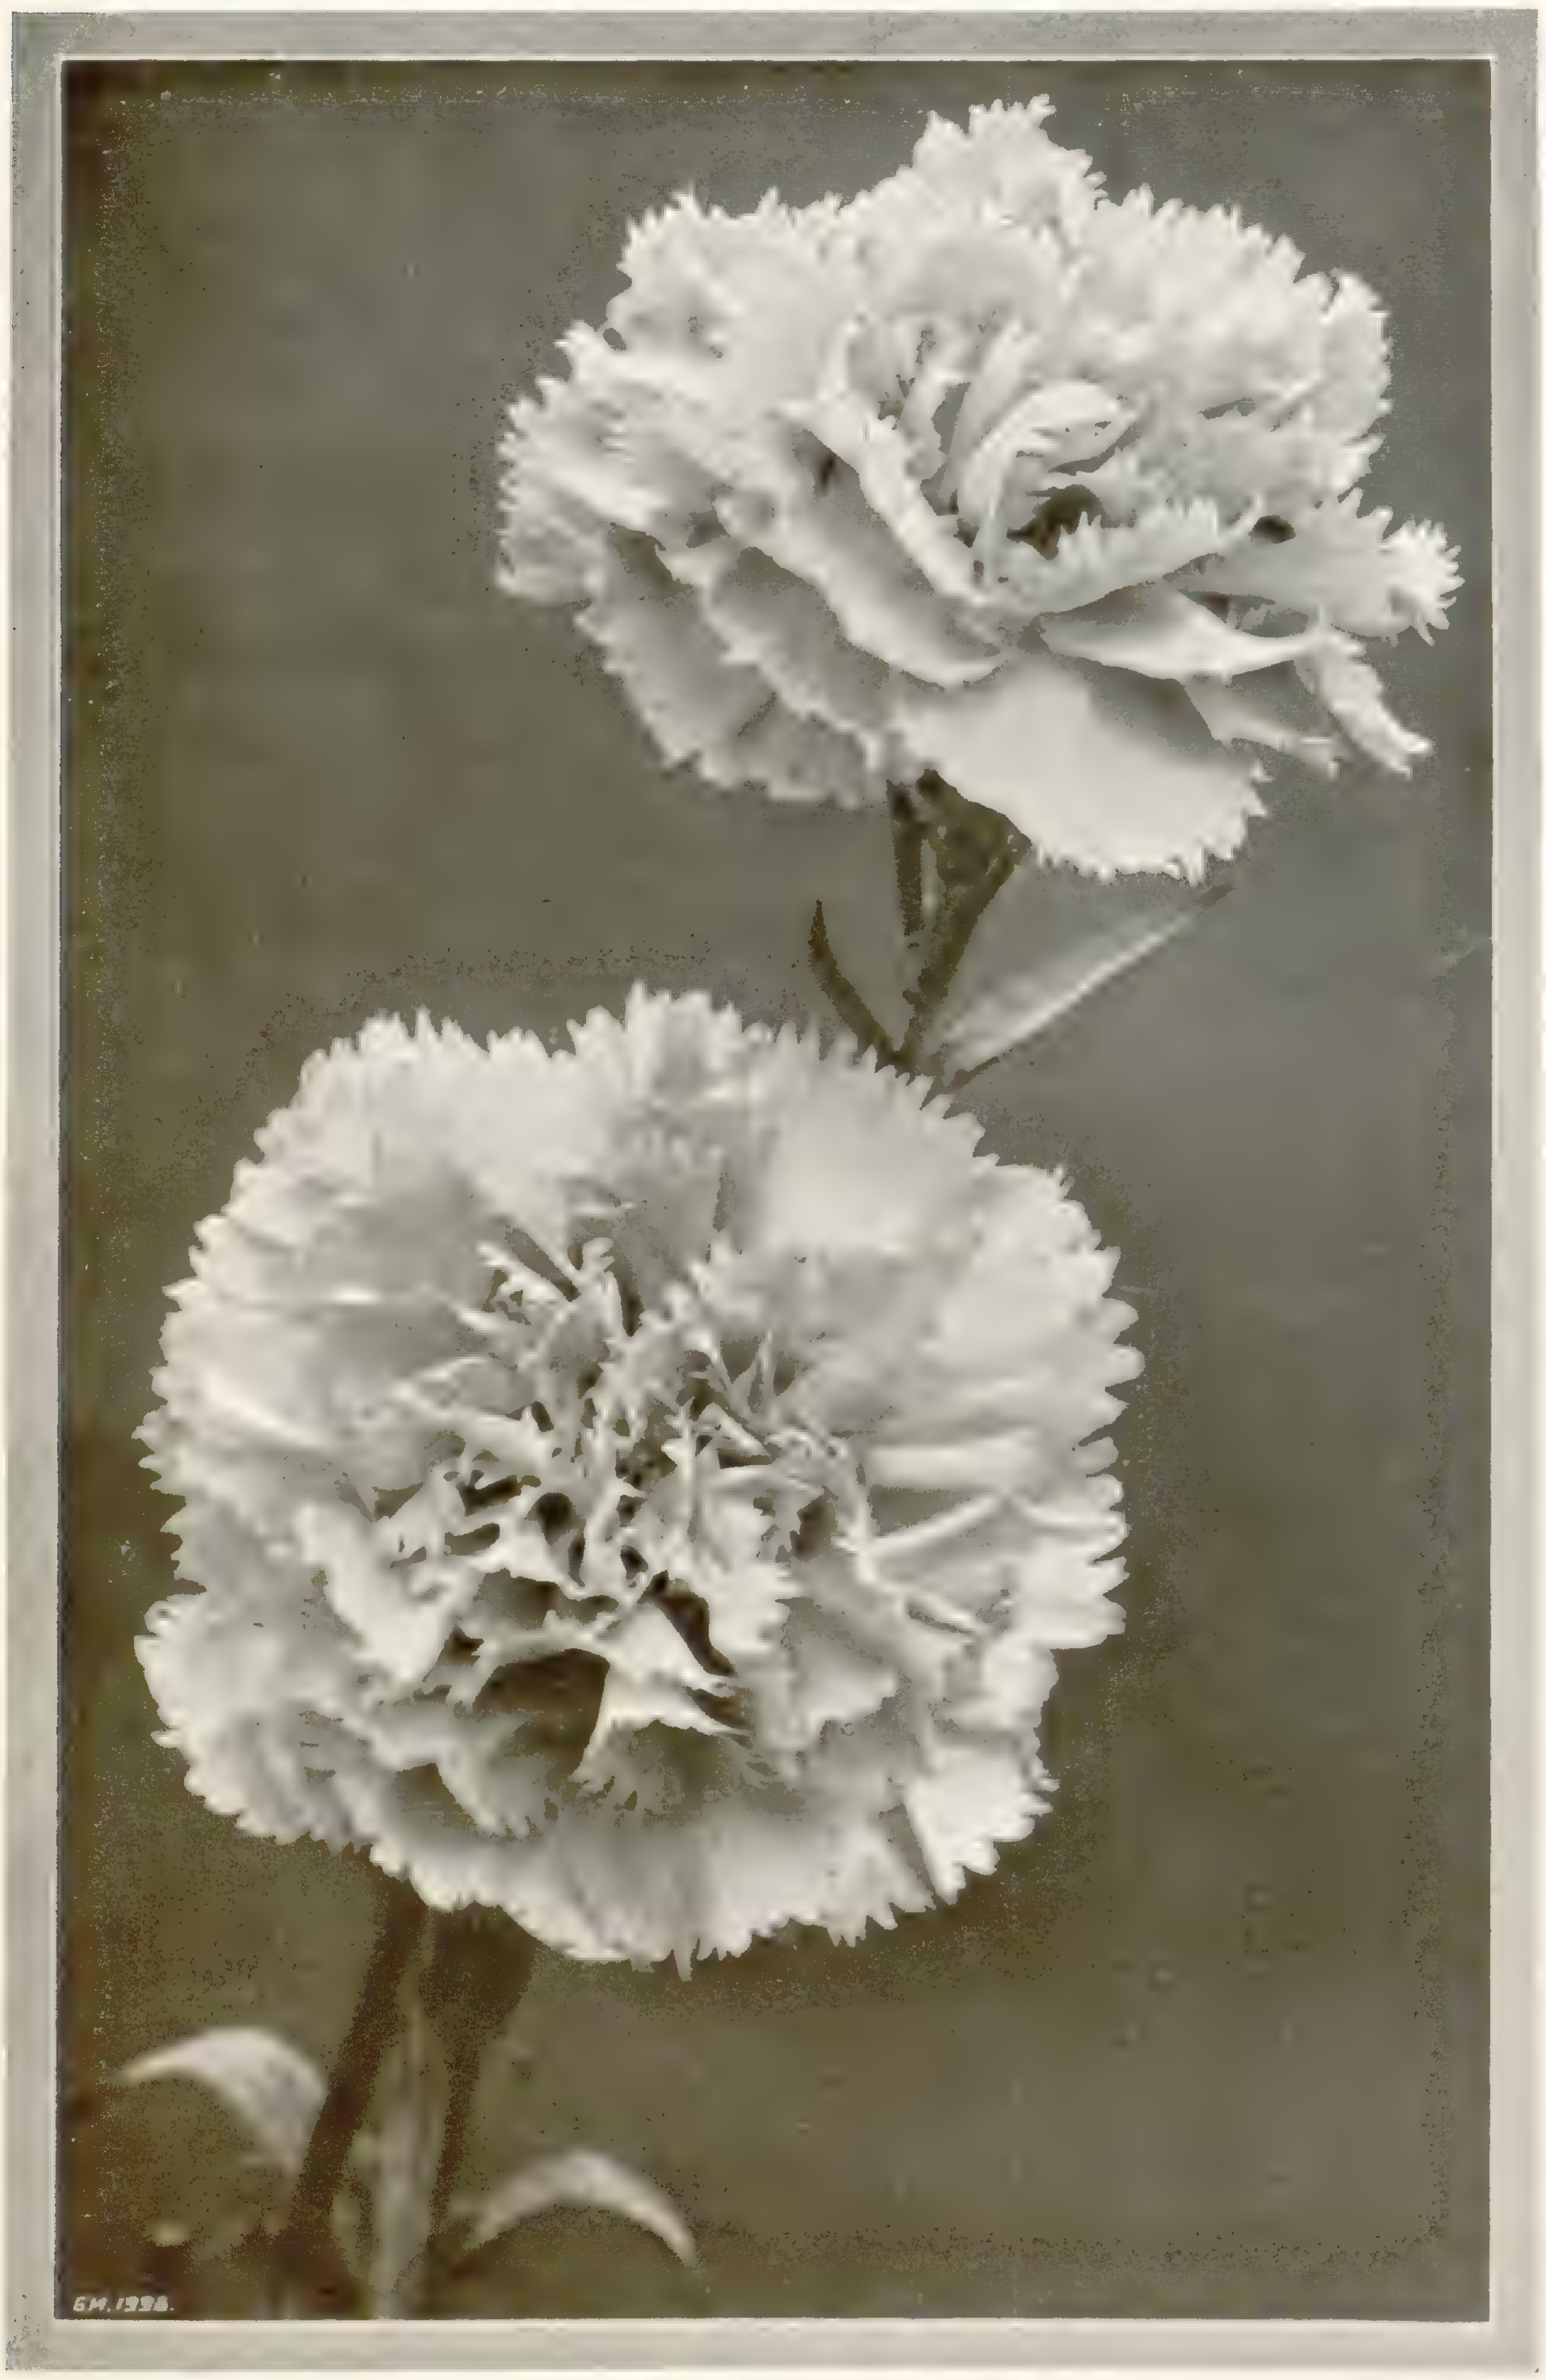


CARNATION WIVELSFIELD WONDER.

A new perpetual variety, white, with rose-pink flaking, introduced by Messrs. Allwood Brothers, Wivelsfield, Hayward's Heath.

TWO GOOD NEW CARNATIONS.

Among florists' flowers the perpetual carnations now figure largely, and, as in the case of all popular subjects, the number of new varieties that make a bid for favour is considerable. Two that have come under our notice of late we figure in the present issue.



CARNATION BARONESS DE BRIENEN.
A beautiful pink perpetual variety, introduced by Messrs. Stuart Low and Co., Enfield.

The variety Baroness de Brienen is one of Messrs. Stuart Low and Co.'s introductions, and is a lovely pink shade, the flowers are large, carried well on long stems, and have prettily fringed petals. The Enfield firm have exhibited this variety very freely during the present year, and, we understand, it bears the name of a Dutch lady who is a great horticulturist, and particularly fond of carnations.

Wivelsfield Wonder is being sent out by Messrs. Allwood Brothers, Wivelsfield, Hayward's Heath, and was well shown by them at the Carnation Show held at the Royal Botanic Gardens during the present week. This is a very large flower, with excellent calyx and stem, and it has very broad petals. The white ground colour is flaked over with a soft shade of rose-pink. Wivelsfield Wonder is a dainty carnation, and its habit of growth and freedom of flowering leave nothing to be desired. This newcomer is a seedling from that fine old American variety, "Bradt," which was one of the parents of Enchantress, as indeed, it has been of many other modern varieties.

"CARNATIONS, PICOTEES, AND PINKS" will tell you plainly how to propagate and grow these favourite flowers to perfection. The work is freely illustrated with plates of leading varieties, and explanatory diagrams as to layering, taking cuttings, fertilising blooms, etc. Price 2s. 6d. net, by post, in box, 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

CAMPANULA HENDERSONI.

A neat campanula that well deserves wider cultivation, and one that promises to obtain a larger measure of popular favour in the near future, is C. Hendersoni. It is generally understood that this foot-high plant is a hybrid between C. albiariæfolia and C. carpatica, and its heart-shaped leaves and pyramidal, racemose method of flowering suggest a combination of the two species indicated. The flowers are very attractive and of a rich mauve rather than a deep blue shade of colour. These are very freely produced over a long period, established plants commencing to bloom in July and continuing well into September. Either for the rock garden or the border, this campanula is a very useful subject, and it is particularly effective when grown in a colony rather than as a single specimen.

TILLANDSIA LINDEN.

Though the order Bromeliaceæ, to which this tillandsia belongs, is a very extensive one, and the blossoms of many of them are particularly showy, yet for some reason or other they are by no means popular in gardens. The species at the head of this note is, except the pineapple, which is cultivated for the sake of its fruit, grown perhaps to a greater extent than any other. It is certainly very attractive, as even when out of bloom it is decidedly pretty, the narrow, gracefully recurved leaves being so regularly disposed as to form a very symmetrical specimen, six inches or a little more in height.

From the centre of this crown of leaves the flower stem is pushed up. It is quite erect, and usually reaches a height of eight inches to one foot, or occasionally more, as individuals vary somewhat in this respect. This spike is on the upper portion for about half its length clothed with two opposite closely imbricated rows of bracts, which when fresh are of a rich bright pink colour, which tint they retain for a considerable time. The flowers do not last long, but a succession is kept up from one spike. They are of a beautiful rich purple colour. As a rule, this tillandsia flowers in late autumn and winter, at which time its bright-coloured blossoms are very welcome. It is a native of the Andes of Peru, and does best in the temperature of an intermediate house. A mixture of fibrous peat, sphagnum moss, and sand suits it well. It needs a liberal supply of water, especially during the growing season. W.T.

Prunus Pissardi.—I was much struck, while visiting a neighbour's garden not long since, with the beauty of this tree grown to form a screen in summer time. Usually, one sees green-leaved trees such as those of poplars planted for the same purpose. But as the screen in question is the only one I have as yet seen, it occurs to me that possibly these deciduous trees are not generally used in the way described. Behind the trees I am now referring to there was a background—at a little distance—of evergreen trees, and the latter served to enhance the beauty of the prunus. The deep crimson-purple leaves are very effective. The flowers are white and develop during March and April. A new form, Prunus Meseri flore pleno is an acquisition; the flowers are large, pink, and double, the leaves being a very bright purple. The last-named is very effective as dot plants in a shrubbery. A deep, loamy soil of a calcareous nature suits the trees very well, although those referred to were growing in a light, sandy medium with a gravelly sub-soil, and they appeared to be thriving extremely well in it.—G. B.

DAHLIAS IN AMERICA.

The dahlia appears to be by far the most popular autumn flower in the United States, if one can judge from the prominence given to it in the horticultural Press in that country. One large trade paper devoted practically the whole of two issues last month to the flower, and its growers. The writers were drawn from all parts of the States, thus showing the interest to be widespread. The reports of their exhibitions were pretty breezy, the cactus type being left almost entirely in the hands of amateur growers, while the trade seemed to devote their attention chiefly to the large decorative sorts, that are more or less neglected in this country. The pæony-flowered section, too, seem highly in favour, while the pompons and singles appear to be quite neglected; in fact, the whole sorts are more highly esteemed. The whole of the trend of the various correspondents clearly implies that the American nation require something large for decorative purposes and while the dahlia cannot be styled a popular flower in this country for this purpose, it is evident our cousins regard it otherwise.

One grower alone mentions growing two hundred and fifty thousand plants, surely a fine dahlia farm, while it is recorded that on October 14 one New York wholesaler handled sixty thousand flowers, two others fifty thousand each, and several ten thousand each. If these are the figures at one market, what must be the sales for the whole of the large markets? The prices, too, are rather astonishing to us, for they range from 75 cents. to three dollars per 100. There is surely money in the dahlia cut flower trade in the States. The best grades of flowers are packed just in the same way as we pack our chrysanthemums, in "bunches" for market; needless to add these are chiefly of the decorative type, because they pack better and keep fresh longer than the cactus forms.

One authority denounces the modern cactus varieties in no unmeasured terms. He is of opinion that the only way to judge the merits of any dahlia is to do so on the plant, and certainly not on the show boards, and that the stem and floriferousness of the plant should be taken into consideration as well as the actual flower. A statement that I think will be heartily endorsed by many on this side of the Atlantic. Our American cousins do not fear to criticise any variety that does not come up to their standard. For instance, a grower from Los Angelos cannot understand why the cactus variety Dreadnought ever saw the daylight; he describes it as a dull chestnut, quickly bleaching to a red, "yet more dull, and about as pleasing, as the colour of my old cow at shedding time." Evidently Dreadnought does not behave so well there as in the land of its birth. Again, he describes J. B. Riding as another candidate for the "junk pile" and oblivion. Well, as far as we are concerned, nobody in this country ever thought it would be a cut flower variety. Still, these breezy descriptions are interesting reading. Mr. G. H. Walker, of North Dighton, records the fact that hundreds of roots in his district did not flower at all owing to the drought, while they were disfigured by frost on September 13, and killed outright on the 28th inst. Another curious incident is recorded by a grower in Indiana, who mentions that they lift all their plants while still in flower to make sure the stock is true to name. Thank goodness we do not have to resort to such drastic measures here to keep our stocks true.

A peculiar planting freak, if I dare so describe it, is mentioned by a writer from Massachusetts, who started planting the first week in May, with, presumably, ground roots, putting out fifteen hundred weekly, the final planting of four thousand cactus varieties taking place the first week in August. Talk about "chancing your luck," what should we think of a dahlia grower planting four thousand dahlias in August? We should think him a candidate either for the nearest workhouse or county asylum. However, we have it that this grower's best results were obtained from the plantings made the last two weeks in June verb sap.

It is very pleasant to read the remarks of Mr. G. W. Kerr, at one time with Messrs. Dobbie and Co., and later with Messrs. Bakers, and a gentleman well known to all the London show habitues. He quotes his experiences with a very large collection in all sections, and mentions the fact that many really good varieties in Great Britain are useless to him in America. He gives lists of the best sorts which one notes are quite up-to-date, as far as European varieties are concerned, and also adds a note that he is raising new varieties in the pæony-flowered section that are superior to existing forms.

Mr. Maurice Field, an authority on the subject, gives the following as some of the best decorative dahlias: Perle de Lyon, Delice, Yellow Colosse, Jack Rose, Jeannie Charmet, Kaiserin Augusta Victoria, and Madame Van den Dael, while the best pæony-flowered are Codsall Gem, Mrs. A. McKellar, Mrs. W. E. Whineray, Mrs. T. G. Baker, Mrs. J. B. Riding, The Geisha, Paul Kruger, and Liberty. Our American cousins are very keen on raising seedlings, one writer remarking that it is quite time they could do without the annual importations from Europe, but I am afraid this is a question that will not trouble us in this country for some time, for they cannot afford to ignore our dahlia novelties any more than they can our roses or sweet peas. In conclusion, one can only marvel at the rapid development of the dahlia in America.

J. B. Riding.

Chingford.

CAMPANULA HENDERSONI.

This plant grows about a foot high, and bears deep mauve flowers.

THE SPECIES OF ARBUTUS.

Although the genus arbutus is not a very extensive one, it contains a number of species which are of considerable worth for decorative gardening, for not only are they handsome evergreens, but they are good flowering trees also, and in some instances the fruits are of a showy character. Unfortunately, they are not adapted for very cold districts, though one species, A. Unedo, may be grown successfully from the Midlands to the South of England, and in favoured places further north. Other kinds which are natives of warmer regions thrive satisfactorily in many parts of the country, while a few sorts may only be expected to succeed in places which are favoured by a particularly mild climate.

The arbutus, as a rule, are increased by means of seeds, though layering may be resorted to, and certain of the rarer kinds are sometimes grafted on to stocks of the commoner ones. They are more tender in a young state than in after life, therefore it is advisable to place young plants where they will receive some protection in the event of severe weather or bitter winds being experienced. This is particularly the case with the S. European, A. Andrachne and the Californian A. Menziesi. It is also necessary to place the plants in permanent quarters when quite small, for they transplant badly, and the removal of large specimens which have grown rapidly is attended with considerable risk. Supposing that lime is not prevalent in the soil to any great extent, there are few kinds of soil in which an arbutus will not thrive, while one or two kinds are known to grow in ground overlying limestone. Soil of a peaty character is well suited for the arbutus, and they revel in the disintegrated granite which is so prevalent in various parts of Cornwall. The common arbutus thrives in the neighbourhood of the sea, and in certain parts of the south and west counties grows to a large size when a wind screen occurs between them and the sea.

They are usually known by the common name of Strawberry Trees, on account of the ripe fruits of one or two kinds being thought to bear some resemblance to a ripe strawberry, but the likeness is more fancied than real. In the following notes attention is only directed to those kinds which are obtainable and are likely to grow out of doors in this country; there are, however, other species, some of which have been introduced and lost, and others which have probably never found their way into our gardens.

A. Andrachne is a native of the region about the Levant, where it is found as a large bush or small tree. Under favourable circumstances it attains a height of 40ft., with a trunk of moderate size. It has been grown in this country since 1724, at which date it was introduced from Smyrna. The leaves are oval or oblong, three to four inches, or sometimes up to six inches long, and a couple of inches wide, deep green above, pale below. The margins are entire, by which means the species is easily distinguished from others. The yellowish-white flowers are borne in erect panicles in spring, and they are succeeded by small fruits, about one-third of an inch in diameter, which, when ripe, are orange coloured, or orange suffused with red. It is said to grow well in soil containing lime. A fine tree is to be seen in the Botanic Gardens at Bath. A peculiarity of the species is noticed in the way the old bark is shed. Towards the middle of summer the bark becomes detached in long shreds or sometimes in patches, and continues to be cast during autumn and winter.

A. furiens is a very different plant from the last-mentioned species. A native of Chili, it grows into a somewhat loose-habited bush with coriaceous ovate leaves, the largest of which are not more than two inches long and an inch wide. The upper surface is deep green, and the under sides glaucous, thinly covered with dark brown hairs. The margins are slightly toothed, and the apex is terminated in a short, sharp point. White flowers appear in short, rather dense inflorescences from the leaf soils during late spring or early summer. At its best it forms a showy shrub, but it is only suitable for outdoor culture in the warmest parts of the country.

A. canariensis may only be grown successfully out-of doors in places like the south-west of Cornwall. It is distinguished by large leaves, which may be eight or nine inches long and two and a-half inches wide on vigorous plants. The inflorescences of yellowish-white flowers are produced in large terminal upright panicles. It is a native of the Canary Islands.

A. hybrida is of garden origin, though it has also, it is said, been found in a wild state in Greece. It is a hybrid between A. Andrachne and A. Unedo and is common in this country. Plants differ somewhat in character as they approach most closely one or other of the parents. The influence of A. Andrachne is usually seen by the way in which the old bark is shed, while the leaf margins are usually serrated as in A. Unedo, though it sometimes happens that the serration is confined to the upper half of the leaf. It blossoms in spring, and is showy when in bloom. An fine tree 39ft. high and 5ft. 10in. in girth at 5ft., and 7ft. 4in. at 3ft. above the ground is figured in Vol. III. of "The Trees of Great Britain and Ireland." This tree is growing at Sedbury Park near Chepstow, and it is said to be the finest known specimen.

A. Menziesi is the Madrona of California, and perhaps the largest-growing species in the genus. Examples are found up to 100ft. in height with a girth of 20ft. It occurs along the Pacific coast of North America, from southern Columbia through Washington and Oregon to California. Though introduced so long ago as 1827, good trees are rare: the few that exist are, however, widely scattered, for they are reported from places so wide apart as Castle Menzies in Scotland, Southampton, Kew, and Tortworth. Its oval leaves measure four to five inches in length, and two and a-half inches in width, though they may be larger on young vigorous plants. The yellowish flowers are borne in upright panicles in spring. During summer and early autumn practically the whole of the bark is cast off in small plates as is usual with the plane tree. Throughout this period the tree creates a most curious effect. In America the wood is used for furniture and for charcoal. For the latter purpose it is said to be specially valuable.

A. Unedo is the common Strawberry Tree, and is more frequently met with in our gardens than any other species. A native of Southern Europe, it is also found wild in some parts of Ireland, notably in the vicinity of Killarney. Fine bushes and small trees may be found in many places, particularly in the south-west counties of England, South Wales, and Ireland. Its dark green serrate leaves are familiar to most people, whilst its terminal heads of yellowish-white or sometimes reddish flowers are as well known as its pendulous, globular, rough fruits, which, when ripe, are bright scarlet or orange-scarlet in colour. A number of varieties are known which differ from the type, either in the colour of the flowers, habit, or in shape or size of leaves. Thus rubra, or Croomi, as it is sometimes called, has reddish flowers; quercifolia has somewhat lobed leaves; microphylla, very small foliage; compacta is of dwarf compact habit; and integerrima has rounded leaves, often with entire margins, and so on.

This completes the species which may be most easily obtained, and a collection of those mentioned would be well worth including in gardens where the more tender kinds would be likely to thrive.

W. Dallimore.

REHMANNIAS AND CELSIAS.

These are both very useful plants for spring flowering in the greenhouse, and they will succeed admirably under similar treatment. Rehmannia angulata is a native of Central China; its flowers are frequently three inches in diameter, they are of a rose-purple colour, and freely produced on tall, erect stems, very similar to a foxglove. The variety known as Pink Perfection is of a lovely clear pink shade, and quite an acquisition.

Of the celsias, C. cretica is the most handsome plant; it has rich yellow flowers closely set on a tall erect stem which frequently attains a height of fully five feet. C. arcturus is dwarfer in habit and less vigorous in growth, only attaining a height of about two and a-half feet. Its flowers are also yellow, and it looks well placed round the base of groups of more imposing subjects.

Seeds of these two classes of plants should be sown in the autumn in a cold frame to obtain specimens for spring flowering. Transfer the young plants from the seed pans to three-inch pots when large enough, and grow them on in a cold frame for the winter, taking care that they are not subject to frost at any time. When nicely rooted shift them into 32-sized pots,in which they will flower. Use a light open compost for the purpose, and make it moderately firm. Celsia Arcturus does not require more root room than a 48 pot affords, and charming specimens are frequently grown in 60 sized pots. Grow them in a cool house, and stake and tie as required. When the flower spikes develop weak liquid manure is a great assistance, and an occasional top-dressing of a fertiliser is very helpful. Water needs to be given sparingly during the winter, especially in the case of the rehmannias. When the blooms commence to expand remove the plants to the show house or conservatory, where they are usually much admired. J. G.

Gaillardias.—The continuous flowering qualities of the gaillardia claim for it at least a passing recognition. As a border plant its merits rank high, for even now, at the end of October, there are many fully expanded blossoms. The stout, firm stems stand it in good stead when the flowers are used in a cut state for indoor decoration.—W. T.

Apple Newtown Pippin.—In the southern counties bushes that are so pruned that the centre is kept open, and grown in a warm sheltered corner, will bear fruit satisfactorily. But in the northern counties the trees do best when grown so that the branches can be trained to a wall with a south aspect. I well remember a fine wall specimen in a sheltered corner near some vineries in a Lancashire garden not more than a mile distant from the sea. This tree was always early in blossom, and, being protected from frosts, the flowers set well, and the fruits were very large and highly flavoured. They kept good until the end of April.—G. B.

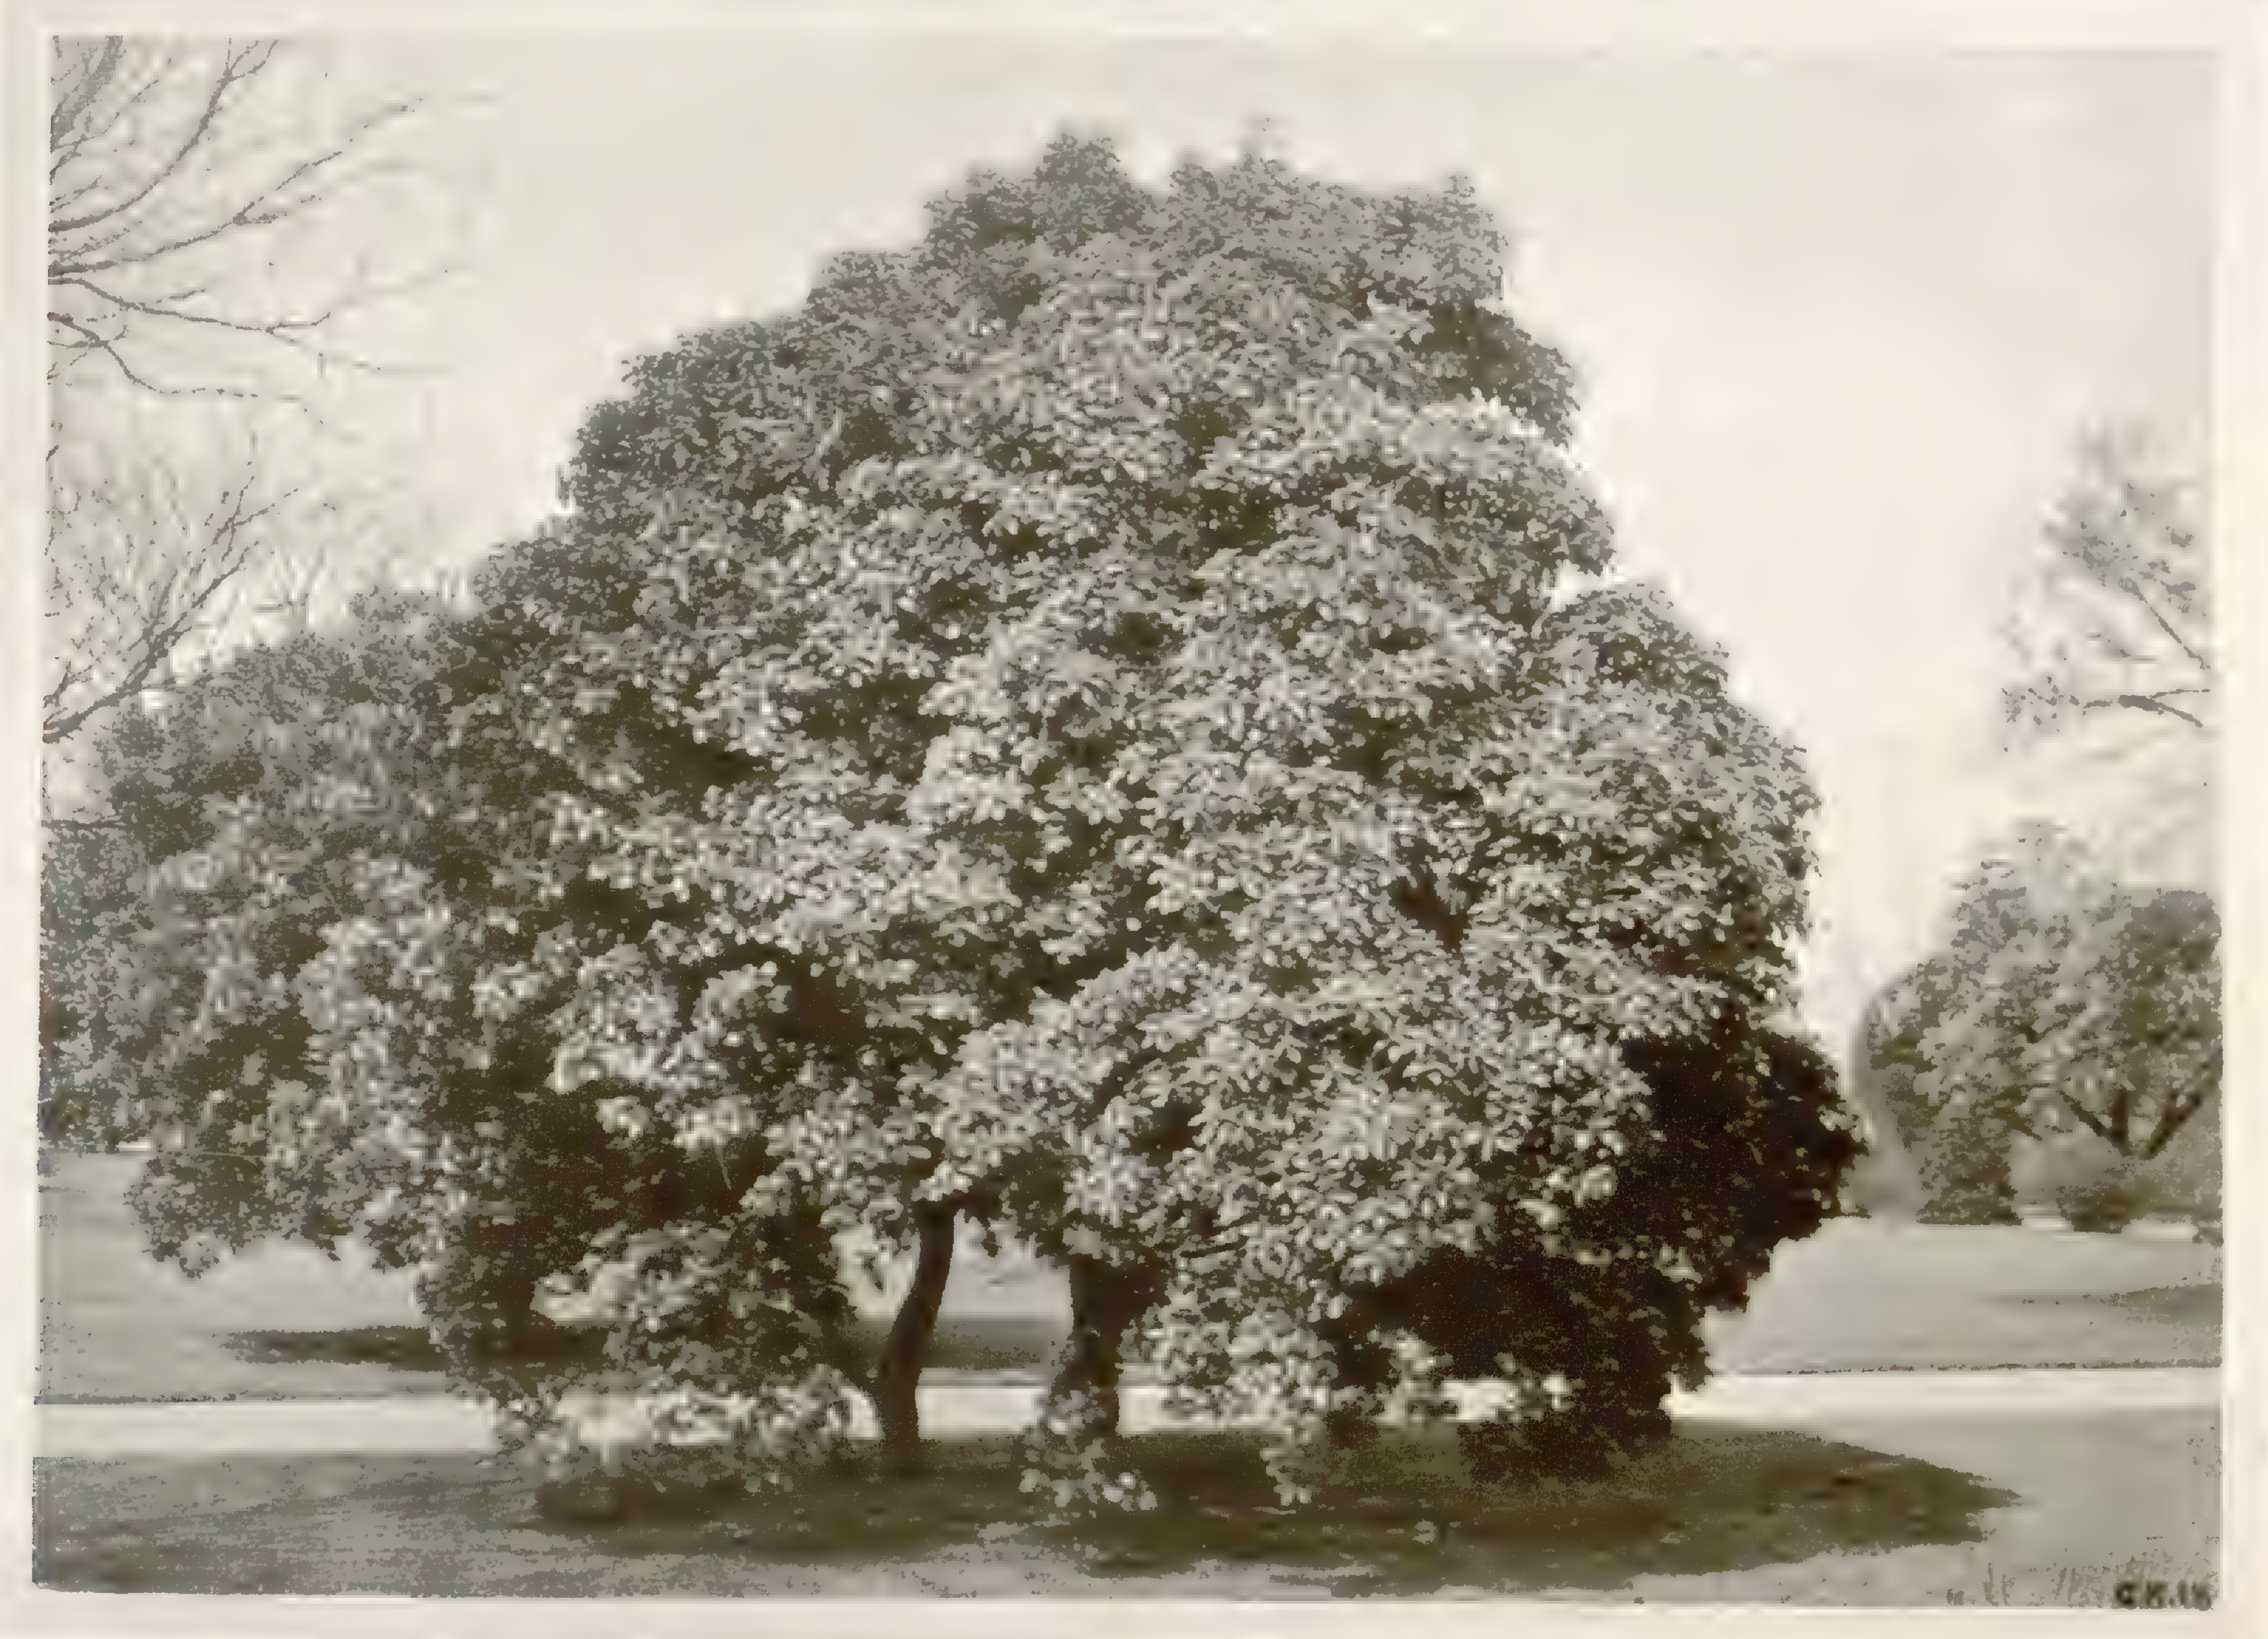
AUTUMN AND WINTER-FLOWERING EVERGREEN SHRUBS.

When the autumn tints have faded, and the leaves of the deciduous trees and shrubs have fallen, it is then we turn our attention to the evergreen species, and though the flowers of these, in many instances, are small and insignificant in themselves, they more than compensate for this lack of beauty by the delicate perfume they impart.

If we take Osmanthus ilicifolius as an example, we find the flowers are small, somewhat resembling those of the holly, clustering round the slender growths, and so inconspicuous that one would not notice them were it not for their delicious fragrance. Osmanthus ilicifolius is not unlike an holly in appearance, and many who are not familiar with shrubs would undoubtedly take the green form, when a small bush, for one, but as the plant grows larger it has a less rigid appearance, and, instead of flowering in the spring, produces its delicate little flowers in November. In addition to the green form, there are several variegated varieties, one having silver variegated foliage, and another golden. A third variety has purple leaves, but all flower alike. O. myrtifolius is another species that is well worthy of consideration. It is upright in habit, the shoots being much stronger than in O. ilicifolius; the leaves, being not quite so large and farther apart, enables one to see the flowers to better advantage. This species makes a neat specimen for the shrubbery border or rockgarden, but should not be grown under the shade of trees. O. rotundifolia is of like character, and should find a place in all gardens. These shrubs thrive best in a light rich turfy loam and decayed leaf-soil. They should be planted in an open situation, where they can be sheltered from the cold east and north-east winds. Though they usually bloom freely at this season of the year, I have never seen them so full of bloom as at the present time. Doubtless this is owing to the beautiful weather we experienced during the summer.

Those who have never seen a fine specimen of Desfontainia spinosa in bloom have no idea of its beauty. This somewhat resembles holly, but on closer inspection it will be found quite distinct. The long tubular flowers, which are produced in abundance all over the plant, are scarlet and yellow in colour, resembling those of a large trumpet honeysuckle. It thrives best in a rich fibrous peat and loam, and it should be given an open situation, sheltered from cold bleak winds. When grown to a height of from five to six feet, and covered with its attractive flowers, it is a fine sight.

I have not seen Elæagnus glabra variegata bloom so profusely as it has done this season. Though the flowers are small in themselves, they are produced in abundance, and, being sweet-scented, are sure to attract passers by. When not in bloom this makes a splendid bush for the shrubbery, its attractive foliage, which at all times of the year looks fresh, being very conspicuous. The plant thrives best in a mixture of light rich sandy loam and fibrous peat.



A TYPICAL SPECIMEN OF THE STRAWBERRY TREE (ARBUTUS UNEDO) AT KEW.

How seldom is it that we see the arbutus doing well, yet there is no reason, provided a suitable position is found, why it should not thrive. In some places, where one would least expect to find it flourishing there we see it in perfection. If there is one thing this shrub dislikes more than another it is the shade of overhanging trees. Grown in an open spot, where it can be sheltered from the cold north and east winds, it will grow and thrive most luxuriantly. It is fibrous-rooting, and on that account the soil used should be made firm when planting. Choose a sheltered position on a dry sunny bank, use light rich soil, well drained, and one will be well rewarded with an abundance of bloom, and clusters of bright red strawberry-like fruits throughout the winter months. The reason so many fail with this shrub is because they place it in a shady place, and plant in a stiff, cold soil. I was looking at some large specimens a day or two ago that are a picture of health, being loaded with clusters of both fruit and flowers. I have seen trees planted out in the open which have not failed to produce a crop of fruit for the last forty years. It is a peculiarity of this species that the flowers of one winter produce ripe fruit the next.

Though the usual time of flowering for the choisya is the summer, in some seasons it will bloom for the greater portion of the year, and this season it appears to be trying to see if it cannot outdo the summer crop of flowers. In sheltered spots it is now in full bloom, and the flowers are very attractive, standing well up above the shining foliage.

The cænothuses also seem to be flowering this season more profusely than I have ever seen them before. The walls are covered with their elegant spikes of pale blue flowers, and some of the kinds, Gloire de Versailles in particular, is quite as gay at the present time, November 8, as during any part of the summer.

There can be no doubt that, with judicious planting and a proper selection of kinds, most gardens may be made interesting during the whole year with these choice flowering shrubs. It is a pity that they are not more extensively planted in the place of the more common kinds, such as the laurel and rhododendron

H. C. Prinsep.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEED SOWING.—Some of the winter-flowering cypripediums and late-flowering cattleyas mature their seed pods about the present time and during the coming few weeks. In the case of cypripediums, the seeds are usually matured at the time of the ripening of the seed vessel, and such seeds may be sown immediately; indeed, I consider that the sooner cypripedium seeds are sown the better it germinates. It may be that, owing to the smaller amount of water the plants require in the winter, the seeds do better, for there can be no doubt about satisfactory germination at this season, and the seedlings grow more rapidly than is the case with us when a portion of the seed crop has been saved for sowing at a later date.

CATTLEYAS AND LÆLIAS, which are now most generally sown on artificially-prepared beds, light is one of the most essential requirements for rapid and successful germination, combined, of course, with warm, humid conditions. The seed pods of most of these orchids burst open while still very green and sappy, and they require careful watching to see that they are kept free from moisture. It is a good plan to cut off the seed vessel with a portion of the flower stalk, and place them in a paper bag with the top left sufficiently open to permit of moisture escaping. Hang these in a dry, light position to assist the ripening of the seeds. I would recommend that the seed sowing of any of these should be delayed until after the turn of the days. There is so little aid to germination until after the middle of January that very little, if any, benefits are obtained by sowing before that time.

SUMMER AND AUTUMN-SOWN SEEDS have not been as satisfactory as is usually the case. In the first place, the hot, dry weather prevented germination, and since the rains we have had so much dull weather that little headway is being made by the seedlings. We find it a good plan to raise the plants that are used as seed beds up to within a reasonable distance of the roof glass; this gives some encouragement from the light, and also minimises the possibility of the potting compost becoming stagnant.

CALANTHE SEEDLINGS, if permitted to remain in the seed beds after the old plants have shed their leaves and require the usual resting conditions, are liable to suffer, and if they lose their leaves also, it is difficult to locate them. We find it best to transfer the seedlings to store pots, where they can be afforded the necessary encouragement to keep them active as long as they show signs of development. They will vary; some will make up a minute bulb about the present time, others will keep on growing, and with the necessary encouragement they may make a pseudo-bulb sufficiently large to enable them to produce flowers in the following autumn and winter.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

PLUMBAGO ROSEA, cultivated expressly as a winter-flowering subject, will be found of much value where cut flowers are in great demand, especially as a subject for dinner-table decoration associated with smilax or Asparagus deflexus. Where two colours are not objected to, I find that if good spikes of lily of the valley are associated with the pink plumbago the colour of the latter is brought out to advantage. After the first batch of blooms have been used up the plants may receive a few light top-dressings alternately with weak farmyard liquid, which will encourage new flower spikes, and a useful successional batch will be provided early in the New Year.

REX BEGONIAS.—These are useful at this season for house decoration. I find ferns are not always available now, whereas foliage begonias are almost at their best, and make a fine groundwork for taller flowering subjects. The winter months offer a suitable opportunity for the propagation of such subjects as Rex begonias. A few of the best ripened leaves are selected and the leaf-stalk placed in the gravel or ashes at convenient places between the plants on the stages; here they are usually kept moist enough by the drainage from the plants, and the occasional damping between the pots, and so good sized plants are produced, and are available much earlier than if propagation is left until the New year.

BOUVARDIAS.—Plants that have been producing a plentiful supply of bloom during the autumn, will by this date be nearly exhausted; the old flowering shoots may be shortened back somewhat, and the plants cleaned. Place the plants into genial growing quarters, use the syringe on all favourable occasions, and apply top-dressings of some approved chemical fertilisers. So treated, and given a light position on the stage, and as near the glass as circumstances will permit, the young shoots will develop strong and robust flowering growths for a successional display.

GENERAL REMARKS.—As the days are each week becoming shorter, and the light is almost at its worst, due regard must be paid to the treatment of stove plants. The conditions not being at all favourable to growth or root action, every effort must be taken to avoid undue excitement by fluctuations of temperature. Extreme care and a great deal of forethought must be exercised in the manipulation of the boiler, and hot-water pipes; overheating will cause serious damage. The temperature of the stove should be brought gradually to its lowest at the end of the year, but it is never safe or advisable to allow a minimum of less than 60 degrees, except in very severe weather, when a few degrees lower will cause no anxiety.—John Donoghue, Bardon Hill Gardens.

FRUITS UNDER GLASS.

EARLY VINES.—Vines started by simply shutting up the house will now be plumping up the buds previous to bursting. Therefore a little heat may be turned on to keep the temperature up to 50 degs. If the vines are in pots, plunged as advised, see that that they are well supplied with moisture. It is a good plan to water twice to make sure that the whole ball of earth and roots is moistened, but never water unless water is required; I prefer to use water a little warmer than the temperature of the house. Syringe the rods freely on all fine days; it makes a lot of difference if there is a tank of water in the house, as in that case there is always a fair amount of moisture in the air. Continue to syringe until the shoots are five or six inches long.

LATE GRAPES.—Cut all bunches and place them in the grape-room, so that the vines may have a necessary rest. Any room, that can be kept dry and at a temperature 45 to 50 deg., will do very well. When the grapes are cut the border can receive attention in the matter of watering, etc. Mid-season vines must be dealt with as circumstances will permit. When pruning, if any eyes are likely to be wanted, take care of the best prunings and tie them in bundles, and label and plunge in ashes in a cool house until wanted.

EARLY FIGS.—Figs in pots, started at the same time as the early vines, must now have another 5 deg. of heat by day and night, allowing the temperature to rise to 60 deg. by day in fine weather. Great care is required in watering and in the avoidance of extremes in temperatures. Permanent trees in borders should now be pruned, cleaned, and made ready for closing. Wash the roof, walls, and trees, and take away as much of the old soil as possible, adding new compost, which should consist of loam and lime rubble with a sprinkling of bone meal.

ORCHARD HOUSE.—Push forward the pruning, and if any trees require root pruning badly dig around them, and heel them right over; if this is done carefully and skilfully it should not interfere with the tree bearing a fair crop next season. Peaches and nectarines, cherries, pears, and plums all respond to this treatment. Black aphis are the worst enemies in cool houses, but sometimes scale will make its appearance, in which case a strong and half-worn paint brush is about the best thing to use to move the insects with, and a strong solution of insecticide. When pruning and cleaning are finished rake away all rubbish and surface soil, and give a light top-dressing of good loam and lime rubble; if the latter is not obtainable give a good sprinkling of lime or gypsum, as this supplies the necessary material for stone formation.

TOMATOES.—Maintain a dry, healthy temperature of 55 to 65 deg.; feed the plants once every week, and keep the soil in a free, healthy growing, condition, with just enough moisture for the wellbeing of the crop, and no more. The plants are fruiting well now. Remove the fruits as soon as ripe, whether required for use or not, as they will keep well for a considerable time if laid in boxes of wood wool.

CUCUMBERS must be kept warm and a moist temperature must of necessity be provided, or the plants quickly fall a prey to thrip and red spider. Spray the foliage lightly as it is tender at this season. Stop the shoots at one joint above the fruit, and cut fruits as soon as ready. Keep the temperature at 65 to 70 deg., and damp the floors occasionally with soot water.—W. A. Cook, Leonardslee Gardens.

THE FLOWER GARDEN.

TREES AND SHRUBS.—The operation of lifting, moving, and replanting large specimens must be carefully carried out. It is necessary that a good ball of earth should remain with the roots, and the latter preserved as much as possible. Of course, when dealing with very large trees or shrubs, a tree-lifting machine and skilled labour should be requisitioned; but a trolly on low wheels or rollers will suffice for medium sized specimens. A trench must be taken out round the plant, of sufficient dimensions to allow proper working facilities, and the size of the ball of earth inside this trench must be governed by the size of the tree. When the trench has been opened deep enough, the ball of soil and roots should be made secure by binding it up with short planks, making them fast with chains or stout ropes. When this part is accomplished the undermining part of the business can be attended to, working the soil from the sides first, and shoring them up before the centre is touched. After the sides are securely blocked up the soil in the centre should be removed, when the whole weight will rest on the side planks. A gangway must be cut down to the bottom level to allow the trolly to pass down, and to be pushed under the ball, when the whole is to be lowered gradually until it rests on the trolley.

MULCHING.—Too much importance cannot be attached to this, for an annual mulching goes a long way towards ensuring the welfare of all shrubs and trees, especially those which have been planted recently. When dealing with young shrubberies the dressing must not be forked in where the roots are very near the surface, but where no roots are found near the tops of the ground, then it may be lightly covered. Old shrubberies should be cleaned through and the dead and decaying wood removed.

PROPAGATION. — Cuttings of various shrubs should be prepared and inserted in nursery beds. Making the cuttings provides employment for rainy days, and if they are heeled in they will be quite safe until the weather is favourable for planting. Laurels, privet, escallonias, wiegelias, Forsythias, aucubas, dogwoods, willows, ribes, are amongst those which may be propagated now. A sandy loam, with a good proportion of leaf-soil mixed with it, is the most suitable for rooting the cuttings, and it should be made very firm by treading.

GENERAL REMARKS.—On wet days cloth shreds may be cut, new stakes painted, old ones sorted and tied up in their various sizes; sheds and outhouses put in order so that a general appearance of tidiness may prevail.—E. C. Pooley, Gnaton Gardens.

BIRMINGHAM CHRYSANTHEMUM SHOW
will be held at BINGLEY HALL,
November 5th, 6th, and 7th, 1912.
ALFRED NOAKES, Secretary, 148, Bristol Street, Birmingham.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

The last exhibition of the year was held on Tuesday, December 5, at Vincent Square, and though it was not so extensive as some recent displays, it was effective and interesting, and there was a quite considerable number of exhibitors. Chrysanthemums, winter-flowering begonias, and orchids—cypripediums particularly, were, with carnations and apples, the chief subjects on view. There was a comparative dearth of novelties.

FLORAL COMMITTEE.

Mr. W. Parrot, Barton Court, Kirtbury, submitted groups of a greenish-yellow, narrow-petalled Japanese decorative chrysanthemum named Mrs. Annie Howard Parrott. Messrs. W. Wells and Co., Merstham, had a quite big group, consisting very largely of single varieties, among which the big sheaves of such fine varieties as Leo, Aurora Borealis, Cannell's White, Ruby Beauty, Mensa, Merstham Jewel, Miss May Thorne, Peter Barnes, and the decorative white variety Mrs. David Syme (A.M.), were very fine.

Across one end of the hall Mr. Davis, gardener to J. Gurney Fowler, Esq., staged 135 freely-flowered plants of Begonia Gloire de Lorraine and its varieties, all grown in 48-sized pots. Mr. G. Lange, Hampton, showed well-grown plants of Begonia Gloire de Lorraine, and made up a considerable group of them; the bright-flowered variety named Glory of Cincinnati gained an A.M., and was much admired. Bouvardias, chrysanthemums, and winter-flowering begonias made up a very attractive exhibit from Messrs. Jas. Veitch and Sons, Chelsea.

A bank of very dwarf poinsettias, from W. D. James, Esq., Chichester, looked particularly fine late in the afternoon, when, under artificial light, the brilliant bracts made a rare show of colour. Messrs. Clibrans', Altrincham, had on view a new winter-flowering begonia named Lady Cooper (A.M.); this has bright cerise pink flowers of great beauty. Bath's Premier (A.M.), a distinct and new soft yellow perpetual carnation, was from Messrs. R. H. Bath, Lim., Wisbech; this is a fine variety, and perhaps its only fault is that it lacks fragrance. We understand it is of Lawson parentage.

The pretty and graceful Primula malacoides was capitally shown by Mr. Gooding, gardener to W. B. M. Bird, Esq., Eartham House, Chichester. Mr. W. J. Godfrey, Exmouth, again showed his fine white anemone-flowered decorative chrysanthemum named Godfrey's Perfection.

Very brilliant were the zonal pelargoniums His Majesty, Winter Cheer, and Fiscal Reformer from Mr. W. H. Page, Hampton, all finely flowered. Mr. Reuthe, Keston, sent a number of nerines; Messrs. Whitelegge and Page, Chislehurst, showed some decorative chrysanthemums, and Messrs. J. Peed and Son, West Norwood, contributed a group of Begonia Gloire de Lorraine.

Cyclamen from the Rev. H. Buckston (gardener, Mr. Shambrook), Sutton Hall, Etwall, were finely grown, and represented a pure white strain. Mr. H. Burnett, Guernsey, had a beautiful exhibit of carnations, and showed Mrs. H. Burnett, R. F. Felton, and Rose Doré very well indeed.

Messrs. W. Cutbush and Son, Highgate, presented carnations attractively, their Goldfinch, Fortuna, Beacon, and May Day being especially good. Spiræas, begonias, heaths, and liliums were also shown by the Highgate firm. Messrs. H. Cannell and Sons, Swanley, put up a very fine lot of zonal pelargoniums, showing these in excellent style; with these were numerous decorative and single chrysanthemums in great variety.

Mr. Vincent Slade, Taunton, was an exhibitor of zonal pelargoniums, and Messrs. J. Bruckhaus, Twickenham, filled one corner of the hall with finely-grown plants of varieties of Begonia Gloire de Lorraine, one named Glory of Cincinnati being noticeable for its brightness and the flatness of its blooms.

A choice collection of ferns, chiefly adiantums, nephrolepis, and platyceriums was displayed by Messrs. H. B. May and Sons, Edmonton. The beautiful Zephyranthes aurea, with lovely golden flowers, was very well shown by Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, and was granted a F.C.C.

Mr. P. Ladds, Swanley Junction, showed some beautiful single chrysanthemums, and we were specially struck with Isabel Gray (A.M.), Merstham Jewel, Cannell's Crimson, Mensa, and Mrs. Higgs. Hardy berried shrubs, particularly aucubas, were largely shown by Mr. L. R. Russell.

ORCHID COMMITTEE.

Mr. Davis, gardener to G. Gurney Fowler, Esq., Glebelands, South Woodford, presented a fine bank of cypripediums in which were set the rare and handsome Odontoglossum Smithi, and Cypripedium Leeanum J. Gurney Fowler. Mr. Hopkins, gardener to F. Wellesley, Esq.; and Mr. Cook, gardener to H. Davidson, Esq., Borlases, Twyford, showed new seedling orchids of considerable beauty.

Mr. Alexander, gardener to Lieut.-Colonel Sir G. Holford, Westonbirt, secured an A.M. for Cypripedium Draco—a giant flower, descended from C. insigne Harefield Hall. Messrs. Hassell and Co., Southgate, had a few pretty orchids on view. Messrs. J. and A. McBean, Cooksbridge, sent forward odontoglossums, cypripediums, and cattleyas, C. Luegæ and C. Fabia were especially good.

Cypripediums were very largely shown by Messrs. Cypher and Sons, Cheltenham, and C. Tityus superba, C. Bingleyense, C. Mdme. Jules Hye, and C. Priam magnificum were conspicuously good. Messrs. Jas. Veitch and Sons, Chelsea, had a pretty exhibit of orchids, wherein Masdevallia Tovarensis, Cypripedium insigne Sanderæ, C. Thalia, C. Maudiæ, C. Milo superbum, and the striking Odontoglossum Aurora (Lambeauianum x Rossi rubescens) were notably good.

Messrs. Armstrong and Brown, Tunbridge Wells, presented a fairly large exhibit of orchids, and we noticed such good things as Cypripedium Thalia gigantea, C. Gaston Bulteel, C. Thalia New Hall Hey var., C. Sir Redver's Buller, etc., etc.

Messrs. Charlesworth and Co., Haywards Heath, showed Vanda cœrulea finely, and also displayed Sophro-cattleya Lotte Müller (F.C.C.), the good old Epidendrum vitellinum majus, Vanda Amesiana, Odontioda Cassiope, and Sophro-cattleya Pandora, the new Trichopilia Gouldi (A.M.), a pretty pink, yellow-throated hybrid from T. fragrans and T. suavis.

In the group from Messrs. Sander and Sons, St. Albans, cypripediums were prominent, and especially good were C. Alabaster ampliatum, C. Hydra, C. Euryades, C. Leeanum, Cymbidium giganteum, Cattleya Dowiana Rosita, etc. Messrs. W. B. Hartland and Co., Cork, brought over Cypripedium insigne Sanderæ and C. i. Harefield Hall, and showed a number of plants of each.

A few cypripediums from Messrs. Mansell and Hatcher, Rawdon, Leeds, included C. Thalia Mrs. Francis Wellesley, C. Leeanum Clinkaberryanum, and C. Œdippe. Messrs. Stuart Low and Co., Enfield, had Oncidium varicosum Rogersi in fine form, Cattleya labiata, Vanda cœrulea, and various cypripediums.

Miss Walters Anson, Broadway, Streatham, showed a fine set of paintings of cattleyas, cypripediums, and odontoglossums.

Mr. E. V. Low, Hayward's Heath, had some fine examples of varieties of Cypripedium Leeanum, and a C. Baron Schroder with nine flowers.

Mr. Chapman, gardener to Mrs. Norman Cookson, Oakwood, Wylam-on-Tyne, sent up the deep rosy Calanthe Chapmani roseus and Odontoglossum crispum Chapmani, finely blotched.

From the Gatton Park collection, Mr. J. Collier, gardener to Sir Jeremiah Colman, Bart., brought the beautiful Cœlogyne Moorei, the large Cypripedium insigne Gatton Park var., and Odontoglossum Goodsoni.

FRUIT AND VEGETABLE COMMITTEE.

Messrs. H. Cannell and Sons contributed a very handsome lot of apples, the fruits large, bright, clean, and well arranged. Mr. J. C. Sutton, gardener to Earl Stanhope, Cheveney Park, Sevenoaks, had also a goodly collection of apples, and arranged popular varieties in dishes and large baskets.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Zephyranthes aurea, from Sir Trevor Lawrence, Bart. (gardener, Mr. W. Bain), Burford Lodge, Dorking; to Sophro-cattleya Lotte Müller, from Messrs. Charlesworth and Co., Hayward's Heath.

Award of Merit.—To Begonia Altrincham Pink, from Messrs. Clibrans, Altrincham; to Begonia Glory of Cincinatti, from Mr. Lange, Hampton; to Chrysanthemum Mrs. David Syme, from Messrs. W. Wells and Co., Merstham; to Chrysanthemum Isabel Gray, from Mr. P. Ladds, Swanley Junction; to Perpetual Carnation Bath's Premier, from Messrs. R. H. Bath, Lim., Wisbech; to Cypripedium Draco, from Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester; and to Trichopilia Gouldi, from Messrs. Charlesworth and Co., Hayward's Heath.

MEDALS.

Silver-gilt Banksian.—To Messrs. Cutbush and Son, Highgate, for carnations, etc.; to Messrs. H. B. May and Sons, Edmonton, for ferns; to Messrs. James Veitch and Sons, Chelsea, for begonias, etc.; to Messrs. H. Cannell and Sons, Swanley, for apples; and to Mr. J. C. Sutton, gardener to Earl Stanhope, Cheveney Park, Sevenoaks, for apples.

Silver Flora.—To Mr. J. Bruckhaus, Twickenham, for begonias; to Mr. H. Burnett, Guernsey, for carnations; to Mr. L. R. Russell, Richmond, for shrubs; to Rev. H. Buckstone, Etwall, for cyclamens; to Messrs. W. Wells and Co., Merstham, for chrysanthemums; to Messrs. Charlesworth and Co., Hayward's Heath, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. James Veitch and Sons, Chelsea, for orchids; to Messrs. J. and A. McBean, Cooksbridge, for orchids; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; and to J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), South Woodford, for orchids.

Silver Banksian.—To Messrs. W. B. Hartland and Co., Cork, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; Messrs. H. Cannell and Sons, Swanley, for pelargoniums, etc.; to J. Gurney Fowler, Esq., South Woodford, for begonias; to W. D. James, Esq., Chichester, for poinsettias; to Mr. G. Lange, Hampton, for begonias; and to Mr. P. Ladds, Swanley, for chrysanthemums.

Bronze Banksian.—To Mr. W. H. Page, Hampton, for pelargoniums; to Messrs. Whitelegge and Page, Chislehurst, for chrysanthemums; to Messrs. Mansell and Hatched, Rawdon, Leeds, for orchids; and to Mr. E. V. Low, Hayward's Heath, for orchids.

Aberdeen.

The annual show of the Aberdeen Chrysanthemum Society was held in the Music Hall Buildings, Aberdeen, and Lady Sempill, Fintray House, Aberdeenshire, performed the opening ceremony amid a large and representative assembly. As is his wont Mr. M. H. Sinclair, the secretary, made admirable arrangements, leaving nothing undone to make the show what it was—a splendid success. The remarkably fine summer we had was reflected in every section of the show—pot plants, cut flowers, fruit, and vegetables.

PLANTS.

For best group of chrysanthemums and other plants, arranged in semi-circular form on a space 10ft. by 5ft., to be judged for quality and effect, the entries were few but good. The silver cup went to Mr. Begg, gardener to Mr. A. R. Gray, Garthdee, his group comprising some capitally grown flowers, large, dense, and well formed, while the decorative varieties were greatly admired for their variety and depth of colour. A fine Kentia and two well-grown examples of Cocos Wedelliana surmounted the group, while round the base were a good show of adiantums and pterises and aspidistras. Second place went to Mr. John Mathieson, gardener to Mr. A. Smith, Craigielea, Aberdeen. The arrangement here was exceedingly good, and had there been quality similar to the first-prize group, the prize tickets would probably have been differently placed. Mr. William Dick, gardener to Mr. A. Ledingham, S.S.C., Queen's Road, Aberdeen, took the third place with a very meritorious group. The decorative varieties in it were well grown and much admired.

The display of chrysanthemums in pots was unquestionably one of the finest ever seen at Aberdeen, the size and singular beauty of the flowers being the main features. For six chrysanthemums, at least four varieties, Mr. Begg again scored in fine fashion, taking first and second places with finely grown specimens. In fact, Mr. Begg had matters pretty much his own way, having, apart from his silver cup for best group, nine first and second prizes in this section—no mean record. Mr. A. Murray, Ashley House, Aberdeen, had also some very fine entries. Ferns were not large in numbers, but were well grown, Mr. James Jamieson, Tillycorthie, Udny, Aberdeenshire, and Mr. A. Duncan, Rubislaw Den House, Aberdeen, dividing the principal honours. Chinese primulas, single varieties, were well shown by Mr. Begg. There were splendid exhibits of orchids, and Mr. Andrew Reid, gardener to Mr. Baird, of Durris, Aberdeenshire, won finely, with specimens of Cypripedium Leeanum and Cattleya labiata; Mr. A. Duncan, gardener to Lord Provost Maitland, Rubislaw Den House, Aberdeen, made a very good second.

CUT FLOWERS.

These made an exceedingly rich display. Mr. J. Jenkins, 419, Clifton Road, Aberdeen, led finely here, taking first place for eighteen blooms, with a capital exhibit. Mr. J. W. Robertson, gardener to Mrs. Redmond McGrath, Leetham Grange, Arbroath, led finely for twelve blooms, his entry comprising some choice examples of Francis Joliffe, Mrs. H. Barnes, Bessie Godfrey, Reginald Vallis, F. S. Vallis, Mrs. R. Davis, Lady Talbot, Victoria and Albert, and J. H. Silsbury. The class for eighteen varieties of decorative chrysanthemums in vases brought out a strong competition, and Mr. John Grigor, gardener to Mrs. Dunbar Dunbar, of Seapark, Forres, made a capital first. Premier honours for best nine vases of decorative chrysanthemums went to the last-named gardener's father—Mr. A. Grigor, Duff House, Banffshire. In the class for twelve vases of single chrysanthemums first honours went to Mr. Robertson, Leetham Grange, for a very fine entry. For the best six vases, single varieties, the chief prizes went to Mr. John Elder, gardener, Norwood, Aberdeenshire.

The Christmas roses forward proved one of the outstanding features of the show. Mr. John Mathieson, Craigielea, Aberdeen, occupied the premier place, closely followed, however, by Mr. William Milne, Corsindae House, Sauchen, Aberdeenshire. For the best six stove or greenhouse flowers (orchids excluded), Mr. Andrew Reid, Durris House, had a fine win with exquisite specimens of Clerodendron Balfouri, Lasiandra macrantha, Anthurium Andreanum album, and Eucharis grandiflora. Mr. Reid also took chief honours for orchids, with exquisite blooms, comprising Cypripedium Lecanum giganteum, Odontoglossum crispum, Cattleya labiata, and C. Callistogeossa, the last a finely grown hybrid.

Table centres formed a very strong section, and some very fine work was shown. An outstanding feature, and one that proved very popular, was the magnificent work done in wreaths, bouquets, crosses, and other designs. Here the Burns family, a name prominent in the florist trade in Aberdeen for generations, had matters pretty much their own way. Mr. A. Burns, jun., New Market, Aberdeen, and his daughter, Miss Alice Burns, Victoria Road, Torry (a suburb of Aberdeen), gained no fewer than fourteen prizes.

FRUIT.

For some years past the British Colombian Government were wont to send a fine display of apples grown in that province, but this year they had none forward. Nevertheless, the display of fruit, especially apples, was a really capital one, and in going the rounds of this section one felt that there was no need to go to British Colombia for apples and pears when quite as good, if not better, were shown from the homeland. The Allington Pippins forwarded by Mr. W. B. Reid, gardener to Lord Lovat, Beaufort Castle, was a revelation of what can be done even so far north as Beaufort Castle. Mr. Charles A. Cumming, Pitgaveney House, Elgin, led in kitchen apples, four varieties, four of each, with exquisitely grown specimens. For dessert apples, Mr. W. B. Reid, Beaufort Castle, had a fine win. Mr. C. Stuart, Raemoir, Aberdeenshire, took premier honours for baking apples. Pears made a capital display, and the honours here were divided between Mr. J. W. Robertson, Leetham Grange, Mr. Charles Cumming, Pitgaveney Gardens, Elgin; Mr. Andrew Reid, Durris House; and Mr. John A. Grigor, Seapark, Forres. Grapes were poorly shown.

VEGETABLES.

The display in this section was not so large as has been seen at this show in former years, but what was lacking in numbers was amply made up for in quality. For the best collection of vegetables the entries were few, but Mr. John Garden Broomend, Inverurie, had a collection that would have compelled attention in any show. It was composed of Up-to-Date potatoes, Ailsa Craig onions, Veitch's Self-protecting broccoli, Solidity Brussels sprouts, St. Valery carrots, and Clark's Empress celery. Mr. William Scorgie, Spinghill House, Aberdeen, made a capital second. Potatoes, as is usual at Aberdeen, made a very grand display, and Mr. A. Gardiner, Drumduan, led finely and followed by Mr. J. Ferguson, Linton House.

AMATEUR SECTIONS.

The amateurs put up a very good display in many of the classes, and some very fine material was shown by Mr. John Davidson, Hardgate; Mr. John L. Milne, Hardgate, Aberdeen; Mr. James Coutts, Sunnybank Place, Aberdeen; and Mr. Alexander Cumming, 83, Cairnfield Place, Aberdeen. The last-named gentleman, who is a printer to trade, won handsomely, for the third year in succession, the first place for six vases of decorative chrysanthemums.

MISCELLANEOUS DISPLAYS.

These were remarkably good, the leading place being taken by Mr. Sinclair, the worthy secretary, with an exceedingly chaste and fine display of plants and flowers. The flowers were the more interesting because of their being, for the most part, uncommon. A number of nerines, of beautiful colour and quaint form, attracted considerable attention. Conspicuous also were some very fine poinsettias. Gerberas, or Transvaal daisies, also of rich colouring, were very pleasing, as were also some fine specimen chrysanthemums in white, bronze, etc. The new varieties of Lorraine begonias were very attractive. Graceful ferns and palms, and a quantity of richly-berried plants, completed a display interesting alike for its quality and the chasteness of its arrangement.

Others who had exhibits were Messrs. Thomas Rivers and Sons, Sawbridgeworth, Herts, and Messrs. George Bunyard and Co., Maidstone, who had remarkably fine displays of apples.

National Chrysanthemum Society.

Amid exquisitely beautiful surroundings, chrysanthemums of all kinds abounding on the tables and in the window spaces, the annual dinner of the National Chrysanthemums Society was held on Wednesday evening, November 29, in the Venetian Chamber, Holborn Restaurant. Sir Albert Rollit, the President, occupied the chair, and was supported by a very large number of folks famous in the world of horticulture and particularly in chrysanthemum circles. The company was a fairly large one, and included a number of ladies.

After the loyal toasts had been honoured, the President presented the numerous cups and medals to their respective winners, adding a few words of compliment and congratulation. Mr. Howe, Mr. Davis, and Mr. Hunt especially came in for very hearty applause.

The chief toast of the evening, "Success to the National Chrysanthemum Society," was proposed by the President, who said the society stood in membership, resources, and reputation higher than ever before. The exhibitions at the Crystal Palace were referred to, and the Palace spoken of as the finest possible place for such great shows. He thought the last November show reached the high-water mark of such displays, and he congratulated the exhibitors on their great accomplishments. The dwarf chrysanthemums and the single varieties appealed to him strongly as well as to the public. The President further congratulated the growers who had so freely given flowers for the decoration of the tables that evening, and Mr. Felton on his successful arrangement of the blooms. The President spoke of the educational value of exhibitions and of the great advance in scientific research in the world of horticulture. Correct knowledge—science—he said, was business and power. The work of the Floral Committee was eulogised by the President, who pointed out that, curiously, at one of its meetings, there were no flowers to consider, and at its latest meeting there were over a hundred varieties to adjudicate upon. The conferences, and the publication of lectures given thereat, the President considered excellent work done by the society. In conclusion, the President had a few words to say with reference to the International Horticultural Exhibition of 1912, and urged that all members of the society should do their best to make that wonderful and unique occasion a huge success, and through the peaceful influence of flowers make also for the peace of the world. To this toast Mr. Thomas Bevan, chairman of committee, responded.

The other toasts given were: "The Donors of Special Prizes," given by Mr. W. Howe, and responded to by Mr. J. R. Jackson (of Messrs. Clay and Son); "The Exhibitors and Affiliated Societies," given by Mr. E. F. Hawes, was replied to by Mr. Norman Davis, the double gold medal winner of November last; "The Chairman," ably proposed by Mr. J. McKercher, met with a suitable response and musical honours; "The Ladies and Visitors" was in the hands of Mr. J. H. Withy, and J. A. Botham, Esq., ably responded. Mr. J. W. Mooman gave "The Press," and this was acknowledged by Mr. J. Harrison Dick, of "The Journal of Horticulture."

Just before Sir Albert's response to the toast of his health, Mr. Bevan interposed to read a resolution passed by the Executive Committee on November 20, placing on record the valuable services rendered to the society by Sir Albert during his several years of presidency. This resolution, suitably inscribed and beautifully bound, was handed to Sir Albert by Mr. Bevan. Sir Albert's very humorous reply was one of the gems of the evening.

Manchester and North of England Orchid Society.

At the November meeting the members present were: Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. Bamber, W. R. Lee, C. Parker, H. Thorp, Z. A. Ward, J. C. Cowan, J. Cypher, J. Evans, W. Holmes, A. J. Keeling, and H. Arthur (secretary).

W. R. Lee, Esq., Heywood (gardener, Mr. Woodhouse), exhibited a group of plants to which a silver-gilt medal was awarded. Amongst the odontoglossums special mention must be made of O. Chione (F.C.C.), O. Antiope (A.M.), and O. Hermione (A.M.) The cattleyas included C. labiata Virgo purissima (F.C.C.). C. Portia var. Imperator (A.M.). C. labiata, var. Genevieve (A.M.), C. Myrrha, Lee's var. (A.M.), C. Iris, var. Corisanda (A.M.), and L.-c. Clive, Plumpton Hall var. (A.M.); the above, with cypripediums and Dendrobium Phalænopsis Schroderianum, made a very good display.

Z. A. Ward, Esq. (gardener, Mr. Weatherby), also exhibited a splendid group, and was awarded a silver-gilt medal, an especial feature being the numerous varieties of the Cypripedium insigne section. C. actæus, Cringlewood var. (A.M.), C. Thalia, var. Mrs. F. Wellisley, and C. Corneyanum were good.

O. O. Wrigley, Esq., Bury (gardener, Mr. Rogers), again staged a magnificent exhibit of over 250 plants, the cypripediums, comprising all the yellow varieties known in cultivation. In the Leeanum section were fine examples of C. L. Clinkaberryanum, C. L. magnificum, C. L. giganteum, and others.

J. McCartney, Esq., Bolton (gardener, Mr. Holmes), was awarded a silver medal for a group, including Cattleya labiata Mrs. J. McCartney, C. Luegæ, C. Mrs. W. H. Whiteley, C. Bowringiana, and others, with plants of Oncidium flexuosum and O. Rogersi.

Rev. J. Crombleholme, Clayton-le-Moors (gardener, Mr. Marshall), staged a very pretty group of cypripediums, including some well-grown plants of C. insigne Harefield Hall, C. Sanderæ, C. Actæus magnificum, C. Mancunium (A.M.), etc., all tastefully arranged with small ferns and palms, a silver medal being awarded.

Colonel J. Rutherford, M.P., Blackburn (gardener, Mr. Lupton), was awarded a bronze medal for a group of cypripediums; and G. H. Peace, Esq., Monton Grange (gardener, Mr. C. Mace) was also awarded a bronze medal for a group of cypripediums.

J. J. Holden, Esq., Southport (gardener, Mr. Johnson), staged a wonderful specimen of Odontoglossum ardentissimum, var. Johnsoni, carrying two spikes of flowers (F.C.C.),, as well as Cattleya Aurora Borealis (A.M.), C. labiata, Holden's var. (A.M.), C. Princess Mary (Warneri alba x Dowiana alba), A.M., and C. Holdeni (Schroderæ alba x Warneri alba), A.M. Messrs. J. Cypher and Sons, Cheltenham, were awarded a silver medal for a group, principally cypripediums. Messrs. Stuart Low and Co., Bush Hill Park, staged a miscellaneous group, to which a silver medal was awarded, cattleyas and cypripediums being well represented. Messrs. Hassall and Co., Southgate, were awarded a silver medal for a meritorious group of cattleyas and hybrids of the iris section, with a few choice cypripediums.

CERTIFICATES AND AWARDS.

First-class Certificates.—To Cattleya Fabia, var. Imperator, a fine flower with aurea lines in lip very distinct; to Cattleya labiata, var. Virgo purissima, a large white flower with pale-yellow markings in the throat; to Odontoglossum Chione, a wonderful flower, solid chocolate colour with segments tipped with white, the lip broad and flat, all from W. R. Lee, Esq.; to Odontoglossum ardentissimum, var. Johnsoni, from J. J. Holden, Esq.; to Cypripedium Overtoni, from R. L. Overton, Esq. (Fulshawense x Leeanum corona).

Award of Merit.—To Cattleya Portia, var. Imperator, large round flower, four inches across, good even colour; to Lælio-cattleya Clive Plumpton Hall var.; to Catleya labiata Genevieve, a white flower with faint markings in lip; to Cattleya Iris, var. Corianda, a very fine variety; to Cattleya Myrrha, Lee's var., a very large flower; to Odontoglossum Antiope; to O. Hermoine, very distinct, and of good form; to Cypripedium Arthurianum var. Sanderæ; to C. Charlesianum, var. Prometheus, very fine; all from W. R. Lee, Esq; to Cypripedium Pearl Beauty (Milo x nitens Charlesworthi), from R. Le Doux, Esq.; to Cattleya labiata alba Holden's var., distinct, but rather small; to Cattleya Holdeniæ (Schrodera alba x Warneri alba), lip tipped with pink, yellow throat; to C. Princess Mary (Warneri alba x Dowiana alba), good variety, showing the Dowiana markings on lip, but rather light in colour; all from J. J. Holden, Esq.; to Cypripedium mancunium (Harrisianum superbum Leeanum), from Rev. J. Crombleholme; to C. Actæus, Cringlewood var., from Z. A. Ward, Esq.; to Cattleya Fabia var. gigantea, from Messrs. Stuart Low and Co., magnificent shape and good even colour; and to Cattleya labiata, from Messrs. Hassall and C., a seedling of good form and colour.

Dundee Chrysanthemum Society.

At the exhibition held on November 24 and 25, the average quality of exhibits was up to, if it did not surpass, that seen at former shows.

In the open section Mr. James Rae, head gardener to Lord Northesk, was the winner of the Corporation Cup, and a substantial prize given for twelve vases of Japanese chrysanthemums, three blooms in each; he had finely-finished blooms, admirably displayed. Mr. A. Duncan, Corbet Castle Gardens, Perthshire, was third. Mr. A. Duncan was the winner for eight vases of Japanese blooms, showing good flowers of Mrs. C. Penford, Buchim Keeling, White Queen, etc.; Mr. David Kiellor was second; Mr. John E. Davis was third. For six vases of Japanese blooms, six varieties, three flowers of each, Mr. R. McNaughton, Battleby Gardens, Perth, was the winner of the Smieton Memorial Medal and £1. Mr. George Mallison, Tarrit Gardens, Cupar, Fife, was second. Mr. Duncan again led with four vases of Japanese incurved varieties, Mr. John E. Davis being second; and Mr. John Fraser, Dryburgh Gardens, Lochie, third.

Mr. Thomas C. Brown, Balcawis Gardens, was first with four vases Japanese blooms, four varieties, winning the Croll Gold Medal and money prize; his varieties, Hon. Mrs. Lopes, A. T. Miller, Mrs. M. B. Marsham, and J. H. Salisbury were shown with splendid finish. Mr. George Scott, Seathwood Gardens, was second; and Mr. David Eggo, Dunalistair Gardens, Broughty Ferry, was third. For two vases, containing six blooms in three varieties, Mr. James Rae was again to the front, followed in order by Mr. James Staward, St. Fort Gardens, Fifeshire, and Mr. George Mollison. For three vases of undisbudded blooms, eighteen sprays in each vase, Mr. George Scott was first, showing Market Red, Le Pactole, and Source d'Or; Mr. James Beats being second, his varieties being Market Red, Redbraes Yellow, and Parson's White. For three vases of single varieties, Mr. James Beats and Mr. A. Duncan were the winners in order named. Mr. David Kiellor was first with one vase of incurved blooms. Messrs. Beats, Rae, and Duncan scored in this order for one vase of twelve sprays of partly-disbudded flowers. Mr. James Bethel, The Grange Gardens, Monifieth, was the winner with two ladies' dress sprays, and two buttonhole bouquets. Messrs. Beats, Scott, and Cook won as named for a shower bouquet, and Messrs. Beats, Bethel, and Scott, in the same order, for a basket of chrysanthemum flowers and foliage.

Dinner-table decorations were good, and Mr. James Beats was the winner with an effective arrangement, composed of single chrysanthemums, Mary Richardson and Kitty Bourne, and tinted trails of Selaginella cæsia. Mr. George Scott was second with similar flowers, while Mr. James Bethel employed chrysanthemum Mary Richardson along with beautifully-tinted trails of Selaginella Cæsia arbora.

In the class for a dozen chrysanthemum plants, not less than six varieties, grown in six-inch pots, Mr. George Scott was first, Mr. James Beats second, and Mr. John Fraser third; Messrs. Beats and Fraser were winners for primulas. Messrs. James Beats and George Scott were the only competitors with three pots of single chrysanthemums. Messrs. Alex. Duncan and Wm. Grieve scored as named for four Lorraine begonias.

The vegetable and fruit section was not a large one, vegetables being confined to a collection of eight kinds, Mr. James Bethel, The Grange Gardens, being the first prize winner; Mr. John E. Davis, Ballathie Gardens, second; and Mr. John Hepburn, Huntingtower, Perth, third. For one dish of kitchen apples, Mr. J. Reid, Rankeillour Gardens, Cupar, Fife, was first; Mr. Wm. Goodall, Errol, second; and Mr. James Staward third. The last-named competitor was the winner for six dessert apples, and Mr. John E. Davis was first for six pears.

The amateurs' section was up to the usual standard of excellence, and Mr. John Oenholm, 292, Blackness Road, practically cleared the boards of first prizes for cut flowers. In the plant section Mr. James Clark, Mr. John Denholm, Mr. A. Hutcheon, and Mr. Wm. Robertson were the first prize winners, Mr. Denholm having the honour of showing the best plant at the show.

The non-competitive exhibits from three local firms did honour to the exhibitors, and proved attractive features to visitors. Messrs. W. P. Laird and Sinclair showed very pleasing and attractive designs in floral work;

Messrs. D. and W. Croll also showed wreathes, bouquets, etc., set out amongst cyclamen, begonias, and cut carnations; Messrs. Harley and Sons also showed bouquets, wreaths, harps, etc.

Bolton.

The twenty-fifth annual exhibition was held in the Albert Hall, and fully sustained the society's reputation for holding one of the smartest and best shows in the district.

For a circular group of miscellaneous plants there were four entries, all worthy of high commendation. These were staged on moss in the centre of the hall, each exhibit was of similar formation with a pyramidal centre surmounted by a palm with dot plants round, and the margin filled in with a variety of foliage and flowering plants. Mr. W. Burgess, gardener to John Harwood, Esq., secured the chief position with crotons, palms, sonerillas, and oncidiums. Mr. H. Thorn, gardener to J. W. Makant, Esq., was a good second, his orchids adding rare colour to the arrangement. Mr. J. Wainwright, gardener to E. T. Crook, Esq., also staged well, whilst Mr. J. Lord, gardener to Alderman Knowles Edge, had excellent examples. The classes for a group of chrysanthemums, undisbudded, brought three entries, all highly creditable, the principal difference being that of colour. The prizemen were Mr. B. Hardy, gardener to G. S. Peck, Esq.; Mr. W. Burgess, and Mr. D. Wilson, gardener to Miss A. N. Philips, Prestwick, who scored as placed. For a group of large-flowered chrysanthemums, Mr. D. Wilson had it all to himself, putting up an effective group with many good blooms. The best table of orchids was from Mr. W. Holmes, gardener to J. McCartney, Esq., who had a charming array, in which cattleyas, oncidiums, and cypripediums were utilised to great advantage.

Roman hyacinths loom large at Bolton, no fewer than three open classes being provided, as well as special prizes. Mr. D. Wilson secured two firsts, and Mr. B. Hardy one first prize. Mr. M. Taylor, gardener to W. Edge, Esq., had the best eight primulas; Mr. James Entwistle led for a vase of carnations; Mr. A. Adshead had the best ball-room bouquet;

and Mr. John Nixon, gardener to O. Robinson, Esq., the best bridal bouquet.

Cut blooms were fine, and Mr. C. Groves, gardener to Sir Gilbert Greenall, Bart., Walton Hall, Warrington, added to his long list of successes by the addition of another silver challenge vase, his success being mainly due to his superior incurved varieties and their form and finish. His best examples were Doris Rayner, Mad. Ferlat, Edwin Short, Clara Wells, Calypso, Charles H. Curtis, Yellow Hygate, Frances Joliffe, Mrs. W. Mease, Kara Dow, and F. S. Vallis. Mr. J. Wainwright second, and Mr. G. A. Chandler, gardener to A. James, Esq., Rugby, third. For thirty-six Japanese blooms, Mr. Chandler took the lead with a very fine set, his leading blooms being F. S. Vallis, Frances Jolliffe, Master James, Valerie Greenham, Eclipse, Willie Rawlings, E. C. Converse, and Reg. Vallis; Mr. C. Dunwell gardener to Chas. Jones, Esq., Abergele, was second. For six vases of singles and six vases of decorative varieties, Mr. A. Adshead took the lead.

For two bunches of black grapes, Mr. R. Jones, gardener to J. Amphlett, Esq., Colwyn Bay, won with good bunches of Alicante; and for two white bunches, Mr. J. Wright, gardener to E. Lord, Esq., Rawtenstall, led with well-coloured Muscat of Alexandria.

A few non-competitive exhibits were staged. Messrs. Sutton and Sons, Reading, set up seventy dishes of potatoes in a most artistic manner, backed by palms and greenery, and with cut lily of the valley between the dishes, the whole making a most effective display, which was worthily awarded a gold medal. Messrs. Stuart Low and Co., Enfield, contributed a pleasing collection of cut carnations, and a table of choice orchids, and this also gained a gold medal. Mr. R. Smith, of Bolton Training College, received a Cultural Certificate for a number of cotton plants well furnished with pods. The Liverpool Orchid Company received an Award of Merit for a small collection of orchids.

East Anglian Horticultural Club.

There was a most interesting assembly of gardeners at the November meeting of this club, held at the Boar's Head Hotel, Norwich. Mr. Lewis Smith, Shotesham Hall Gardens, and Mr. Geo. Davison, Westwick House Gardens, gave their impressions of "The British Fruit Show," and on Norfolk-grown fruit in particular, in a very lucid manner. Mr. John Willis sent his weather report for the past month, which showed how, with a fall of the temperature, we had had an abundance of rain and some severe gales.

The exhibits placed upon the tables, both competitive and non-competitive, were at once attractive and educational. One or two subjects of importance were a Pitmaston Duchess pear scaling 2lb. 6oz., which Messrs. Daniels Bros., Lim., staged, and was grown by Mr. G. W. Musk, Wiseton. A twin apple brought up by Mr. Frank Neave, Lingwood, and a fine cattleya from Mr. W. Shoesmith, gardener to F. W. Harmer, Esq.

Subsequently, Mr. E. Peake gave a lantern lecture upon "The Fertilisation of Plants." He started with the lowest forms of vegetation, and by the aid of beautiful microscopic slides, showed their means of propagation. From these he dealt with mosses and their bi-sexual character, and then led on through the cryptogamous plants to those where organs of fertility are very pronounced. Some pictures were afterwards shown of some of the local hybridists in their gardens, and the lecture concluded with a description of a ramble through Denmark, where Mr. Peake spent a holiday, observing the horticultural and agricultural industries of the country. Thanks were accorded to the lecturer for his services.

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price 10/6. Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).

Smithfield Show.

The great Stock Breeders' and Farmers' Show, which opened on Monday, December 4, and continued until Friday, was a grand success in every respect, and one of which British agriculturists might well be proud. To the gardener, the splendid exhibits arranged in the galleries by the leading seedsmen were of particular interest. The examples of vegetables and produce exhibited here are always of what may be termed sound utility type, and the show is of importance to the grower for profit, or the gardener who has a large household to cater for. A word of praise is due to the growers of the really handsome swedes, mangolds, and other roots, which, in view of the severity of the past summer's drought, were especially noteworthy.

On Messrs. Sutton and Sons' splendidly arranged stand we found Prizewinner mangold, Up-to-Date swede, and a number of other excellent varieties, represented by specimens about as near perfection as we are at present able to interpret the term.

There were also on view excellent onions, tomatoes, potatoes, and other vegetables of which the quality was superb.

Messrs. J. Carter and Co., High Holborn and Raynes Park, had a great display of their Goldfinder mangold, and a number of capital swedes, etc. Potatoes, carrots, onions, and beetroots also played their part in a stand of great attractiveness and merit. On Messrs. J. K. King and Sons' stand from Coggeshall we noticed particularly some excellent bulbs of an onion called Reading Exhibition Globe. It is a really good onion, fine in skin, and of capital shape This, although a special feature, was but one among many good things this firm staged.

Messrs. E. Webb and Sons, Wordsley, had their usual stand, which was well decked with mangolds and swedes of rare quality. The front of the stand was furnished with King Edward VII., New Majestic, New Industry, and other potatoes of good quality, together with beautifully shaped carrots, onions, etc.

Messrs. Fidler and Sons, Reading, were large exhibitors of potatoes. To mention but a few of the first-rate varieties staged, we may name Dreadnought, Invincible, Eclipse, and Epicure.

As is customary, Messrs. Harrison and Sons, Leicester, brought a capital lot of onions, among which their Excelsior showed up well. Harrison's selected Banbury Cross is a good type, and so indeed is every onion shown by this firm. Of course, there were carrots, beetroot, potatoes, and other vegetables, as well as farm roots, shown on the Leicestershire firm's stand.

Apples were well shown by the King's Acre Nurseries, Lim., who had a big collection of the best dessert and culinary varieties. Messrs. Horne and Sons, Cliffe, Rochester, also showed apples in good style. Messrs. W. and J. Brown, Stamford, showed young trees, as well as the fruit.

Jacobinia chrysostephana.—This showy member of the acanthus family recently referred to in the GARDENERS' MAGAZINE, furnishes a good illustration of the fact that a plant may be known in this country for years before its merits are properly recognised. This Jacobinia was introduced from Mexico, and distributed by the late Mr. William Bull, of Chelsea, in 1871, yet it was about 20 years after that it became generally grown.—W. T.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

BACTERIOSIS OF THE TOMATO. — S. A. S., Leeds: In reply to your second question, we may state that the symptoms indicating the presence of bacteriosis in tomatoes are well marked. Infection usually takes place at or near the tip of the stem, the disease gradually working downwards, passing into the leaves and flowering shoots as it does so, until the root is reached. Shortly after infection the uppermost leaves commence to wilt, curl up, and turn yellow. The leaves become marked with many rather small, scattered, blackish-brown blotches, and long dark-brown streaks appear on the surface of the stem. If the stem be cut across, the vascular bundles or woody portions present a brown appearance, and on microscopic examination the vessels are found to be teeming wtih bacteria. The fruit also becomes more or less covered with dark-coloured blotches, which at first are quite superficial, but gradually increase in size and assume a watery consistence, finally collapsing and forming irregular pits on the surface of the fruit. After the spots on the fruit, which are at first crowded with bacteria, have collapsed, various kinds of fungi and bacteria gain an entrance through the broken fruit, which is speedily reduced to pulp. Diseased plants gradually droop and die from the top downwards.

BLACK HAMBURGH GRAPE IN A COLD HOUSE.—J. E. S., Kessingland: If by a cold house you mean an unheated vinery, and we gather that is what you mean, we would say at once that excellent Black Hamburgh grapes can be and are grown in such structures, though, of course, the grapes ripen much later than in a heated house. We have seen and tasted capital grapes of this variety grown in unheated houses, and, as far apart as North Devon and East Anglia, and in our present issue we illustrate a vinery at Norwich, where this fine grape is grown exceedingly well without the aid of artificial heat.

PLANTING BULBS.—S. R. T., Nuneaton: The results may not be quite so good as from October planting; nevertheless do not hesitate to plant bulbs at once. Thoroughly dig the ground, adding a good dressing of the old leaf-soil, and a couple of ounces of bone-meal to every square yard of surface. Make firm by treading, and plant the bulbs.

GARDEN DIRECTORY. — F. M., St. Albans: There are two directories of gardens and gardeners, and each contains further information of a horticultural character. The "Horticultural Directory" (1s.) is published at 11, Mitre Court Chambers, Fleet Street, London, E.C. The "Garden Annual and Address Book" (1s., or 1s. 6d. in cloth), is published at 17, Furnival Street, London, E.C. A distinct directory, giving the names and addresses of all the horticultural societies in the United Kingdom, and including a list of the public parks and gardens, with their area and superintendents, is the "Gardening Year Book," post free 1s. 2d., from the GARDENERS' MAGAZINE office, 148-149, Aldersgate Street, E.C.

ODONTOGLOSSUM ARDENTISSIMUM. —E. H., Shipley: It is a by no means uncommon thing to find the strong-growing

hybrid odontoglossums making two new growths, and also producing a flower spike. If the new growths are only just pushing, and the spike is well advanced with the buds soon to expand, you need have no fear, as it will not be necessary to pot the plant for some little time to come. Do not leave the spike on the plant after the buds have all expanded, but cut and use it so as to allow the reserve force in the pseudo-bulb to concentrate on the new growths. Early in the new year when new roots are being formed potting may be done. Use osmunda or polypodium fibre, with sphagnum and a few broken oak or beech leaves as compost.

ALICANTE GRAPE. — M. E. W., St. Leonards: According to Hogg and Barron, the correct name of the very popular late grape is Alicante, and not Black Alicante. Dr. Hogg stated: "It is the Alicante of Speechly; it is also the true Black St. Peter's (not West's St. Peter's), and in my investigations of the vineyards of the South of France I have found it under the name of Espagnin Noir. The name of Alicante is given to several varieties of grapes in the South of France, and in the Peninsula, but it is not applicable to any variety in particular. In the department of Gard it is applied to Gromier du Cantal; in Andalusia to the Tintillo and Tinto, in Provence to Mourvéde; and in the Eastern Pyrenees to Matara. Then the Alicante of Bouches-des-Rhone vineyards is the Granaxa of Arragon, and Granache of the Eastern Pyrenees; while in the neighbourhood of Alicante, the name is given to two or three different sorts. In Great Britain Black Prince is sometimes, but erroneously, called Alicante; and the variety which is the second edition of 'The Fruit Manual,' was called Kempsey's Alicante, I have discovered to be nothing else than the Morocco." The late Mr. A. F. Barron, referring to the Alicante grape, wrote: "It is no doubt the same as Speechley's Alicante, but it is to Mr. Meredith, late of Garston Vineyard, that the credit for the popularity of this grape is due. His excellent and extensive cultivation of it led to its being called Meredith's Alicante, in order to distinguish it from Kempsey Alicante, at that time much praised and recommended, but which ultimately proved to be Black Morocco."

DIVIDING HARDY GERANIUMS. — C. P., Ruabon: It is too late in the year to divide and replant geraniums, especially the choicer sorts. The work should have been done in September or October. In the spring when the weather becomes warmer and new growth commences, the plants should be divided. Hardy geraniums are not fond of disturbance.

NAMES OF PLANTS.

G. A., Poole.—A fruit of Akebia quinata.

L. C., Winchester.—Pieris floribunda, better known as Andromeda floribunda.

N. S. P., Windsor.—1, Erica hyemalis; 2, Aralia elegantissima; 3, Daphne Cneorum.

T. W., Jersey.—1, Benthamia fragifera; 2, Escallonia macrantha; 3, Trachelospermum jasminoides.

A. B. J., Chesterfield.—1, Sparmannia africana; 2, Masdevallia Tovarensis; 3, Exacum affine; 4, Jacobinia chrysestophana.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, Gardeners' Magazine, as advised in the notice at the head of "Answers to Correspondents."

W. H. W., Romford.—1, Golden Spire; 2, Blenheim Pippin.

A. M., Marlow.—1, Mère de Ménage; 2, Margil; 3, Gravenstein; 4, Warner's King; 5, Golden Noble.

A. L. J., Haywards Heath. — 1, Court Pendu Plat; 2, Ribston Pippin; 3, not recognised; 4, Bramley's Seedling.

H. R. T., Folkestone.—1, King of the Pippins; 2, Baumann's Red Reinette; 3, Bramley's Seedling; 4, Beurre Clairgeau.

OBITUARY.

MRS. T. COOMBER.

We regret to learn of the loss our friend and coadjutor, Mr. Thomas Coomber, of The Hendre Gardens, Monmouth, has sustained in the death of his wife. Mrs. Coomber passed away peacefully on the morning of Tuesday, December 5, after a long and painful illness. To Mr. Coomber and his three sons and daughter we tender our deepest sympathy.

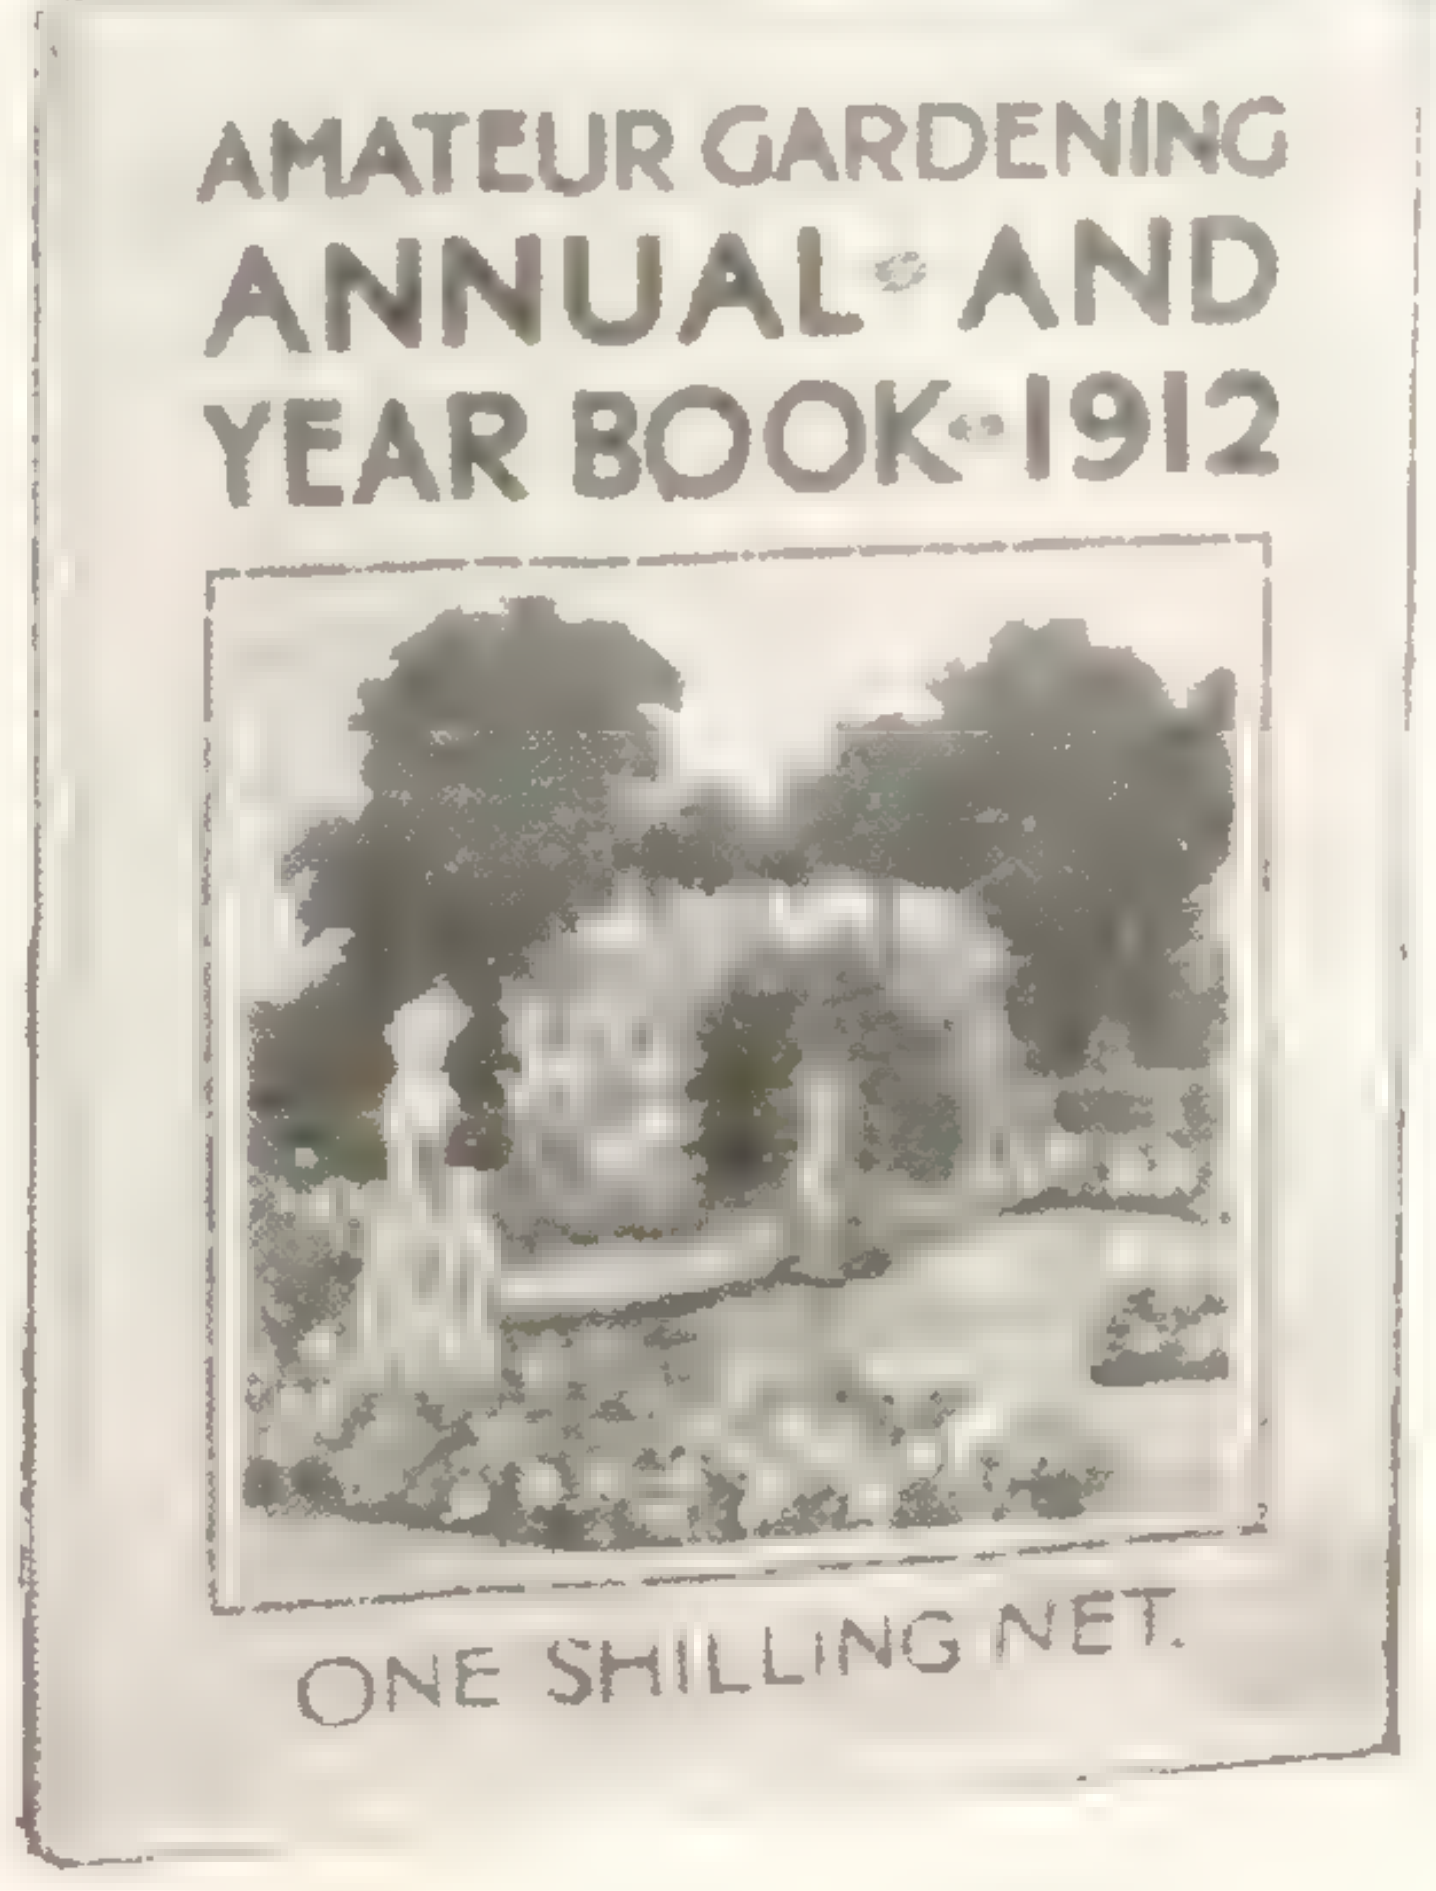
One Shilling Net.

AMATEUR GARDENING ANNUAL AND YEAR BOOK 1912.



184 DEMY 4to PAGES, 116 ILLUSTRATIONS, PRINTED ON ART PAPER, BOUND IN ART COVER.

SOME OF THE CONTENTS: Work for the Month in Flower Garden, Greenhouse, Orchard, Kitchen Garden, &c.—Sweet Peas—Hardy Annuals—Carnations—Bulbs—Water Gardens—Begonias—Rockeries—Gladioli—Violas—Roses—Pergolas—Delphiniums—Orchids—Dahlias—Tulips—Chrysanthemums—Phloxes—Hyacinths—Fruit—Lawns—Vegetables—Spraying—Manures—Insects—Indoor Garden—Select Perennials, Biennials, and Annuals—Sowing and Planting Tables—Etc., Etc.

A FEW EARLY APPRECIATIONS

"It is a wonderful Shillingsworth and should be immensely popular."

"It is a very fine book indeed, and should command a good sale. The advertisements equally with the reading matter are very well set up and attractive."

"I may say that on perusing the "A. G. A," I consider it a very pretty and useful edition and especially instructive. Trusting you will have a good demand for same."

"We are much taken with the issue and feel confident it will be carefully and studiously used by your many admirers and readers. It has not been our experience heretofore to have so much information—good sound and practical information—packed into such compass. The Annual is full of interesting articles from beginning to end. The shot you have fired will certainly strike the Amateur."

"I think it is a most useful and charming book and it should have a large sale."

ONE SHILLING NET OF ALL BOOKSELLERS, NEWSAGENTS AND BOOKSTALLS.

Employment THE GARDENERS' MAGAZINE Register.

The charge for an Advertisement INCLUDES A FREE ENTRY ON THE REGISTER. Immediate Notice must be given when an engagement is secured.

NOTE OF THE WEEK.

Cult of the Sweet Pea.

MR. F. W. LADDS.

The large and representative gathering of cultivators, raisers, and others specially interested in the sweet pea at the annual meeting of the National Sweet Pea Society on the 8th inst. proved to demonstration that the interest in this exquisitely beautiful and delightfully fragrant flower is in no way abated. There were sweet pea enthusiasts from all parts of the United Kingdom, and, as evidence of their devotion to the flower, it may be mentioned that, with few exceptions, they took part in the several meetings, and evinced the keenest interest in the proceedings, which, with a short interval for dinner, extended over nearly eight hours. The committee were able, as will be seen on reference to our report which appears on another page of this issue, to present to the members a highly gratifying report. There was a large accession of new members during the year; and, although there was a decrease of about one-third in the receipts for admission on the occasion of the exhibition in July last, and a grant of £25 was made to the funds of the Royal International Horticultural Exhibition to be held in London next year, the year's work was brought to a close with a good balance in favour of the society. This was regarded as highly satisfactory to the general body of members, as evidenced by the manner in which they brushed away the proposal for the appointment of a sub-committee to investigate the finances of the society with a view to greater economy in expenditure. The society had expended £15 more on printing and stationery than in 1910; and, notwithstanding the fact that the drafting and confirming of a set of rules for governing the constitution and duties of the Floral Committee, and a large increase in membership, necessarily involved additional expenditure, the appointment of a sub-committee was proposed, to enquire into the finances. This point would have been wanting in general interest, and we should not have referred to it, were it not for the fact that the appointment was moved and seconded by two members of committee, who, by virtue of their position, should have been fully informed on all financial matters. The committee presented for adoption by the members a new set of rules, with which were incorporated those relating to the Floral Committee. The majority of the proposed alterations were in every way desirable, while a few—and these not the least important—were otherwise; and the members, very wisely, did not accept the alterations. The committee proposed an addition to the rule governing the constitution of the Floral Committee that would have excluded from that body all who were directly or indirectly interested in any of the varieties under trial. As a considerable number of the leading authorities on sweet peas are raisers of new varieties, or commercially interested in them, this addition would have had the effect of excluding a very considerable proportion of those who have the fullest knowledge of varieties. It is, of course, essential that raisers should not vote for their own varieties when inspecting the trials, but this is effectually guarded against by a rule relating to the method of conducting the trials. All the varieties are grown under numbers, and the vote of each member of the Floral Committee is entered on a card, which is handed to the secretary at the close of the inspection. When the votes are counted, any that may have been given by a member in favour of a flower in which he is interested is disallowed. This rule effectually prevents a member judging his own flowers, should he desire, which we do not regard as at all probable, to do so. The Floral Committee now and again comes in for a share of criticism, and this is not at all surprising when we consider how many beautiful sweet peas, owing to their being too much like other varieties not less beautiful, or from some other cause, fail to obtain recognition. There is also a possibility of some failing owing to the plants not making so robust a growth in the trial grounds as in the raiser's garden; and, when this happens, there is necessarily some amount of disappointment. We sympathise with those who suffer disappointment, and at the same time fully appreciate the splendid services the society has rendered cultivators by its trials, both in bringing novelties of merit into prominence, and in dealing with questions of nomenclature. With a second set of trials conducted under different conditions of climate and soil, this branch of the society's operations should be of still greater value. Whether the preliminary arrangement for conducting the latter at Hinckley will be carried out, has yet to be determined by the executive; but it will be matter for regret if it should fall through. The soil of the proposed trial ground was described by one of the leading growers as all that could be desired, and the trials would be under the charge of a scientist with much experience in experimental work. A strong plea was made for holding the northern trials near Ulverston; and, if the results thereof depended wholly upon the zeal of the sweet pea enthusiasts in the district of which that favoured town is the centre, they would be highly satisfactory. To obtain trustworthy results from the trials of sweet peas, as of other classes of flowers, and also of vegetable crops, they must be under the direction of someone who has had experience in such work, and is therefore in a position to fully appreciate the importance of uniformity in the soil, and of the details being carried out in the most exact manner, and is also fully conversant with the difficulty of avoiding error.

Mr. F. W. Ladds, of Swanley Junction, is a famous grower for market, and now the most prominent member of the firm of Phillip Ladds. Mr. F. W. Ladds is a great believer in new methods, and quick to see the good that may lie under a passing suggestion of some observer or grower. Having satisfied himself that any new idea is valuable from a market grower's point of view, he puts it into practice with a vigour that is refreshing, and at the same time astonishing, to older and conservative growers. Mr. Ladds is a great believer in the decorative value of single chrysanthemums, but flowers with one row of petals only do not appeal to him, because they lack substance. He is an extensive grower of chrysanthemums, and has latterly taken up the work of raising new varieties; and already he has obtained many successes with single and decorative sorts. He is very emphatic in his belief that every chrysanthemum valuable to a market grower is a variety of first-rate usefulness for the private grower. His judgment is excellent, and in later years he has become a very prominent member of the National Chrysanthemum Society's Floral Committee. He freely dispenses any knowledge gained, and does not lock the gate of his nursery against either trade or private growers. At the recent Chrysanthemum Conference he gave an admirable account of his methods of producing cut flowers for market, and this we have the pleasure of publishing in the present issue.

Proposed National Diploma in Horticulture.—We are informed by the Rev. W. Wilks that the Council of the Royal Horticultural Society have requested the following gentlemen to act as a Committee to enquire into the desirability of establishing a National Diploma in Horticulture, and if it is thought desirable, to recommend what steps should be taken for the purpose: The Right Hon. A. H. Dyke Acland, Mr. W. Bateson, M.A., F.R.S., Mr. E. A. Bowles, M.A., Mr. F. J. Chittenden, E.L.S., Professor J. B. Farmer, D.Sc., F.R.S., Mr. C. R .Fielder, V.M.H., Mr. W. Hales, Mr. J. Hudson, V.M.H., Professor Keeble, M.A., D.Sc., Sir Daniel Morris, K.C.M.G., V.M.H., Lieut.-Colonel D. Prain, M.A., F.R.S., Mr. H. J. Veitch, V.M.H., Mr. Walter P. Wright.

Proposed British Gardeners' Dinner.—A desire is being felt in horticultural circles that a gardeners' dinner should be arranged in conjunction with the Royal International Horticultural Exhibition, to be held in London in May next, and steps are being taken to ascertain the views of the general body of gardeners with reference to the desirability of such function. Mr. Alex. Dean, V.M.H., who is taking a leading part in what is being done, writes: "Kindly grant me a space in your columns on behalf of the members of the Gardeners' Dinner Committee of 1903, to inform your readers that, assuming a favourable response be made, it is proposed to organise in connection with the Royal International Horticultural Exhibition of May next a similar reception and dinner to that held in 1903, which resulted in a very remarkable success. The members of the above-named committee have recently met for consultation, and have, with a view to obtaining, if possible, some expression of opinion from the gardeners of the kingdom, requested me, on their behalf, to communicate with you and thus inform your readers of what is proposed. I need hardly say that only in the case of a favourable response from gardeners would arrangements for the dinner be proceeded with. Whilst it is known that great receptions, conferences, and banquets will be arranged by the Exhibition Executive, the Council of the Royal Horticultural Society, and other distinguished bodies, these functions will be chiefly provided in the interests of visitors from all parts of the world. The Gardeners' Dinner Committee therefore hold that the British gardener should not be overlooked, and hence have put forward the dinner proposal for May next, as mentioned. If the date for such dinner be fixed for the first week of the Exhibition, it must be as late as Saturday, May 25, seeing that preceding days are fully occupied with important functions. Admission to the exhibition will that day be 1s. for gardeners, and 2s. 6d. for their wives. On the previous day it is 2s. 6d. for the gardener and 5s. for the wife, thus making the visit, especially to gardeners coming from distant parts of the country, very expensive. During the ensuing week the charge for admission all round is 1s., but it is feared few gardeners would care to come far to see the Exhibition at so late a period. The proposal of the Dinner Committee is that dinner tickets shall not exceed 5s. each, and that gardeners' wives would be welcomed. Will all gardeners who favour the proposed dinner kindly send along to me a postcard to that effect at an early date. The committee will then have authority on which to act." Mr. Dean's address is 62, Richmond Road, Kingston-on-Thames.

Princes' Street Flower Garden, Edinburgh.—At a recent meeting of the Parks Committee of the Edinburgh Corporation the question of making an alteration in the arrangement of the flower beds in East Princes' Street Gardens was considered. Mr. J. F. McHattie stated in his report on the flower garden that, owing to the growth of the lime trees on either side of the terrace garden alongside Princes Street, the flower beds are much shaded, and also that they are overcrowded. As a consequence thereof, the effect produced is not commensurate with the labour involved in the management of the flower garden. Mr. McHattie suggested that fourteen beds, of large size and informal in design, be substituted for the fifty-four beds that now have a place on the plateau. He also suggested that the lawn near the railway be converted into a flower garden; and that the 10ft. border alongside the railway be increased in width to 30ft. Mr. McHattie submitted an alternative plan for the arrangement of the flower garden alongside Princes Street. By the adoption of this plan the boundary railing would be removed, and the present garden be divided into four sections, each with a set of flower beds. After some discussion further discussion of the plans was adjourned.

Fruit Conference at Ashford.—On Monday last a conference of fruit growers was held at Ashford, Kent, in conjunction with an exhibition of hardy fruit. The exhibition of fruits was held in association with the Ashford Cattle Show, and was under the direction of the authorities of Wye College. There were two meetings during the day, and at both Lord Northbourne presided. At the first meeting Mr. E. S. Salmon, of Wye College, gave an address on the control of Apple Scab (Fusicladium dendriticum) by the use of Bordeaux mixture and lime-sulphur wash. At the second of the two meetings Mr. Smith, also of Wye College, gave an address on grading and packing, followed by a practical demonstration.

Sale of Poisonous Insecticides by Nurserymen.—A new Order-in-Council, which comes into force on January 12, 1912, has reference to the Poisons and Pharmacy Act of 1908, and amplifies the provisions of the Act in a manner that will benefit all who are engaged in the sale of poisonous compounds for agricultural or horticultural purposes. Hitherto the actual licence-holder must be the seller; in future licences will be granted to the traders' assistants, at a charge not exceeding 5s. The following are the regulations that apply to this new state of affairs: 2.—(1) Where the applicant for a licence under Section 2 of the Poisons and Pharmacy Act, 1908, is a person in the employment of a person who has obtained a licence under that section, the application shall be made in the second form set out in Schedule A to these Regulations, and the forms of licences, applications for the renewal of licences, and renewals of licences, shall be those set out in Schedules B, C, and D, to these Regulations, and the maximum fee charged for the grant of a licence shall be 5s. instead of the maximum fee specified in the principal Regulations, and so much of the principal Regulations as requires an applicant to publish notice of his intention to apply for a licence in two newspapers shall not apply. (2) A licence granted to such an applicant as aforesaid shall not continue in force after the licence of the person in whose employment he is is revoked, or whilst it is suspended. 3.—The following regulations shall be substituted in place of No. 14 of the principal Regulations: A poisonous substance shall not be sold except in an enclosed vessel or receptacle, as received from the manufacturer, distinctly labelled with the name of the substance and the word "Poison," and with the name and address of the seller, as provided by Section 17 of the Pharmacy Act, 1868, and also with a notice of the special purpose for which it has been prepared. For the purposes of this Regulation the person on whose behalf any sale is made shall be deemed to be the seller.

Paris Chrysanthemum Committee.—This committee, formed by the National Horticultural Society of France, is composed of the leading French chrysanthemum growers, together with a few foreign ones, and issues regularly an Annual Bulletin for the use of its members. The current number is just to hand, and contains 170 pages of text, with some illustrations of last year's Paris Show. The contents may be briefly summarised as follows: List of Officers, Floral Committee, Schedule, Report for 1910, Revised List of Varieties recommended for various purposes, List of Prize Winners at last year's Show, Report of the International Show and Congress held in Paris last autumn, together with the text of the papers read, reports of various local shows, and, finally, a list of members of the committee. This latter alone occupies twelve pages, or something approaching 400 members; some people would almost consider the committee a society in itself.

Electro-chemical Culture of Plants.—At the gardens of the Royal Botanic Society on Saturday, the 9th inst., Mr. Emile Lowitz gave a demonstration of Dr. Franz Muller's invention for the utilisation of electricity in the cultivation of various kinds of plants. In describing the apparatus, Mr. Lowitz stated that with its aid it was possible to invigorate trees or plants, and to pump food into them for the purpose of promoting their growth, and to induct insecticides and fungicides for the purpose of exterminating parasitic enemies. He also claimed that the invention was of value for the acceleration of the germination of seeds, the regeneration and the revitalisation of plant life, the extermination of parasites, and the treatment of soil. It was claimed that not only did the apparatus accelerate the germination of seeds, but in the case of old seeds a much higher percentage is obtained when they are assisted with electricity. In the course of the demonstration wheat showed signs of germination within fifteen minutes of being sown and subjected to a strong electrical current.

Certificated Gardeners.—The North of England Horticultural Society have under consideration the question of preparing a scheme for awarding certificates to gardeners, the awards made to be based on the manner in which the gardens are kept. It has been proposed that at the request of the owner of the garden, the society shall send a deputation to consider the granting of a certificate to the head gardener, the time of the visit not to be notified to the latter. Under the scheme there are to be three grades of certificates, and the grade awarded will be determined by the number of marks given by the deputation. The maximum number of marks suggested is 100, and these are to be given, in equal proportions, for cleanliness and tidiness, cultivation of useful crops, glass culture and method, management, experimental work, and possession of Royal Horticultural Society and other certificates. Market gardeners, amateurs, schoolmasters, and others may also ask to be certificated on the same lines. The scheme shows considerable ingenuity on the part of those responsible for its preparation, but we fear that it will fail to satisfy the desires of those who are anxious to obtain a diploma, or some other proof of their skill and of the position they should occupy as practical horticulturists. There is, of course, no better test of the skill and administrative ability of a gardener than the garden: but in many cases gardeners are severely handicapped by the unfavourable position of the garden, the unsuitability of the glass structures, or the amount available for the upkeep being insufficient for the requirements. The question is an extremely difficult one, and merits the fullest discussion; and, if we are unable to accept this scheme as being exactly what is wanted, we regard it as deserving of the fullest consideration from those who are interested in improving the status of gardeners generally.

Presentation to a Scottish Gardener.—The other evening a number of the friends of Mr. James Henderson, gardener at Elmbank, Dumfries, the residence of J. Wyllie, Esq., assembled in the Globe Hotel, Maxwelltown, Dumfries, for the purpose of wishing happiness to Mr. Henderson in his approaching marriage, and to present him with an arm chair as a token of their esteem. Mr. Robert Little acted as chairman, and Mr. David Kerr made the presentation, which he did in an apt manner, eulogising Mr. Henderson's personal qualities, and his ability as a gardener, and wishing Mr. and Mrs. Henderson every happiness.

A Veteran Gardener's Retirement.—There has just retired, after 60 years' service, Mr. Alexander Davidson, gardener, Cairngall, Aberdeenshire. For this long period he acted as head gardener to three generations of the Hutchison family. Born at Summerfield, Aberdeen, over 80 years ago, Mr. Davidson served his apprenticeship at Lockhead, Aberdeen, afterwards working as journeyman for short periods at several places in and around that city. He then received an appointment as under gardener at Ellon Castle, Aberdeenshire, where he remained two years, when he was appointed head gardener at Cairngall. There he has remained until a few days ago, a most faithful, capable, and honoured servant. On Mr. Davidson taking up duty at Cairngall, the estate was under the supervision of the late Mr. Robert Hutchison, who, as the eldest son of the previous proprietor, Colonel Hutchison, acted as managing trustee of the family. After Mr. Robert's death, in 1861, the estate was purchased by Mr. William Hutchison (a grandson of the Colonel's), who had then returned from China, after a very successful career as a tea planter there. He died in 1881, and was succeeded by his son, Mr. W. E. Hutchison, the present popular and highly-respected proprietor of Cairngall. By all these proprietors Mr. Davidson was held in high esteem, both as a competent and skilled gardener, as well as one of the most trustworthy of men. With the residents of the village adjoining the mansion, and his fellow-servants, his kindly manner and obliging disposition endeared him to all. As a judge at many local and other flower shows, Mr. Davidson's services were ever in great request and most ungrudgingly given, his wide and accurate knowledge in matters horticultural, giving weight and satisfaction to his awards. He was also a most enthusiastic Volunteer, joining the corps then known as the "Buchan Rifles." Rising from private, he in 1895 retired with the rank of quartermaster-sergeant, after 34 years' service. For over 50 years Mr. Davidson has also acted most acceptably as parish librarian, while, in the palmy days of the Mutual Improvement Associations, he took a very prominent part.

THE LATE SIR JOSEPH DALTON HOOKER.

Full of years and of honour, one of the most wonderful men of modern times passed to his rest on Sunday last. Sir Joseph Dalton Hooker, O.M., C.B., G.C.S.I., K.C.S.I., F.R.S., etc., etc., had reached the advanced age of ninety-four years with all his faculties unimpaired, save for a little difficulty in hearing.

Born at Haleworth, Suffolk, on June 20, 1817, Joseph Dalton Hooker went early in life to Glasgow, where his father, Sir W. J. Hooker, held the post of Regius Professor of Botany to the University. Here he was educated and took his M.D. degree in 1839, thus, like many other famous botanists, commencing the business of life with the study of medicine. He did not settle down to the ordinary life of a doctor, but immediately began to travel. It is not too much to say that Sir Joseph Hooker will be as much remembered for his travels and his keen observations of all that he saw, as for his botanical work. At any rate, the public will continue to appreciate his "Himalayan Journals," a delightful book of travel, long after it has forgotten the "Genera Plantarum" or the "Flora Antarctica."

THE LATE SIR JOSEPH HOOKER.

Just after taking his degree, when twenty-two years of age, Hooker obtained the position of assistant surgeon and botanist to the Antarctic Expedition then about to start under the direction of Sir James Clark Ross. He joined the "Erebus," and during three years in Antarctic regions, he accumulated valuable botanical and geographical information, meanwhile enduring many hardships and learning many lessons that were to stand him in good stead later on. Returning home, he was for a short period assistant botanist at Edinburgh University, but in 1845 he became botanist to the Geographical Survey of Great Britain. This task was not altogether to his liking, as the roving spirit had taken hold of him, and so, in 1847, he visited the unexplored region of the Sikkim Himalaya to study the flora and collect specimens. He undertook this mission under the persuasion of Dr. Falconer, then superintendent of the Calcutta Botanic Gardens, and because he wished to add to his own knowledge of plants. Of the manner in which this expedition was initiated he wrote: "On hearing of the kind interest taken by Baron Humboldt in my proposed travels, and at the request of my father (Sir William Hooker), the Earl of Carlisle (then Chief Commissioner of Woods and Forests) undertook to represent to Her Majesty's Government the expediency of securing my collections for the Royal Gardens at Kew; and, owing to the generous exertions of that nobleman, and of the late Earl of Auckland (then First Lord of the Admiralty), my journey assumed the character of a Government Mission, £400 per annum being granted by the Treasury for two years." For three years he explored the Himalayas, and for a greater part of the time had only natives with him, though Dr. Campbell joined him later, and the two were held prisoners for some time by the Sikkim Rajah. Dr. Hooker, as he then was, revealed to us the wonder and beauty of the Himalayan flora, especially its rhododendrons, collected thousands of herbarium specimens, and added very materially to the geographical knowledge of what was then an almost unknown region. The "Rhododendrons of the Sikkim Himalayas," the "Flora Indica," and the "Flora of British India," all very largely from the pen of Dr. Hooker, were the outcome of this expedition, while the "Himalayan Journals" give a very graphic account of the scenery, flora, and people of Sikkim, and of the hardships endured and difficulties surmounted during the three years.

In the world of horticulture Sir Joseph Hooker was as well known as among botanists. In 1841, when Kew became a public institution, Sir William Hooker was appointed the first Director, and in 1855, his son became Assistant Director, succeeding to the directorate in 1865, on his father's retirement. Sir Joseph was Director of the Royal Gardens, Kew, until 1885, when he was succeeded by Sir William Thiselton Dyer. His work at Kew can be seen to-day, as the general plan of the famous gardens is due largely to his efforts, and he practically founded the museums there. This position, however, did not entirely overcome his desire for travel, and so in 1860 he visited Palestine, and in 1871, with Mr. J. Ball and Mr. G. Maw, he went on a botanical expedition to Morocco, and these three were the first Europeans to climb to the top of Jebel Tezah, a height of 11,972ft. In 1877 he visited America, and, together with Professor Asa Gray, took up the study of the Rocky Mountains flora.

It was Sir Joseph Hooker and Sir C. Lyell who induced Charles Darwin to place before the Linnean Society, in 1858, jointly with Dr. A. Russell Wallace, the first exposition of the "Origin of Species," the papers being presented under the title of "On the Tendency of Species to form Varieties; and on the Perpetuation of Varieties and Species by Natural Means of Selection." Sir Joseph was a friend of, and in sympathy with, Darwin, and stood by him when the views then expressed did not meet with general acceptance. In 1868 Sir Joseph Hooker was elected President of the British Association, and his presidential address on that occasion was a remarkable defence of Darwin's views, and, by the light it threw upon the subject, went far to settle the great battle that raged over Natural Selection. In 1873 Sir Joseph was elected President of the Royal Society—the highest honour to which a scientist can attain—and this position he held until 1878. Few men have deserved, and few received, so many honours as he. The Royal Society awarded him its Royal medal, the Copley medal, and the Darwin medal; the Society of Arts, the Royal Geographical Society, and the Linnean Society each awarded him highest honours, and the Universities of Oxford, Cambridge, Edinburgh, Dublin, and Glasgow conferred honorary degrees. He was appointed a C.B. in 1869; made K.C.S.I. in 1877, and G.C.S.I. in 1897; and on his ninetieth birthday, in 1907, he received the Order of Merit.

In every sense of the word Sir Joseph Hooker was a great worker; as explorer, scientist, and organiser his name will be honoured for all time, while his voluminous writings provide an enduring monument. In addition to works already mentioned it is worthy of note that he edited the "Botanical Magazine" for thirteen years; his "Students' Flora of the British Isles" is still a standard work; with Mr. Bentham he published the "Genera Plantarum," the "Icones Plantarum" is largely his work, and the issue now in the press shows that right up to the last he retained a firm grip of the science of which he is a lasting ornament. He was a prodigous worker, and his extraordinary wealth of knowledge included many other sciences besides that of botany and medicine. He believed that a botanist should travel and see for himself how and where plants grow, and not be content alone with herbarium specimens; and, because of his breadth of view that resulted from travel, his kindliness as a man, and his passion for work, Sir Joseph Hooker exercised a remarkable influence in the scientific world and won the love and honour of all who knew him.

As was fitting, the Dean of Westminster offered the family permission to inter the cremated remains of Sir Joseph Hooker, in Westminster Abbey, among the nation's honoured dead. This offer the family felt obliged to decline as it was Sir Joseph's special wish that he should be buried by the side of his father at Kew, and the funeral was arranged to take place at Kew Parish Church on Friday (December 15) at 2 o'clock.

THREE BITTER HERBS.

The poet Cowley, who lived in an age when herbs were in great domestic favour, wrote:

> "What savour is better, if physic be true,
> In places infected, than Wormwood and Rue?"

thereby mentioning two of the bitterest herbs known.

In olden days Wormwood was, observes "The Globe," held in great importance, and the Mexicans, when keeping the festival of the Goddess of Salt, began with a dance of women who danced all night wearing garlands of the plant. Wormwood was once noted as an antidote to the poison of toadstools, hemlock, and the biting of the shrew-mouse or sea-dragon, whereas in modern times it is chiefly used in the making of absinthe.

In bygone days it was laid among furs as a preventive of moth, most people thought owing to the bitterness; but the herbalist Culpeper says: "I was once in the Tower, and viewed the wardrobe, and there was a great many fine cloaths (I can give them no other title, for I was never either linen or woolen draper); yet as brave as they looked, my opinion was that the moths might consume them. Moths are under the dominion of Mars; this herb Wormwood (also an herb of Mars), being laid among cloaths will make a moth scorn to meddle with the cloaths, as much as a lion scorns to meddle with a mouse, or an eagle with a fly." So we learn that moths are martial creatures in spite of their dull, homely looks.

Wormwood was one of the herbs that was antagonistic to witches, who disliked all yellow flowers, and the reason may have been that, as these were often dedicated to the sun, they were naturally at war with anything mysterious and gloomy. Wormwood, indeed, has so much power against evil spirits that in some places it is known as the "girdle of St. John." In more modern days it is often called "old woman" by provincial people, which shows how much more humble its station has become; however, it bears also the names of "wermuth" or "keep courage," because it is supposed to act as a good nerve tonic and restorative. The Romans gave Wormwood as a prize to charioteers. Pliny thought the plant so useful that they could have wanted nothing better; and it has been supposed that the idea of giving it to them was to counteract any giddiness they might feel. "You can cure yourself of dizziness," says Strabo, "with the bitter leaf of Wormwood."

Mugwort, which grows in hedges, and is first cousin to Wormwood, but lacking its volatile oil, was used instead of tea sixty or seventy years ago by the working classes of Cornwall, and is said to make a good savoury stuffing to goose. Its principal interest lies in the old stories and superstitions connected with it. In olden days young girls used to hunt for "a coal under its roots" to put beneath their pillows, as it was supposed to make them dream of their future husbands; and it was said that if a coal should be found at its roots on Midsummer Eve, whomsoever carried it about with him would be safe from plague, lightning, and the ague. Later writers suggest that these supposed "coals" were only dead roots, and Gerard, the herbalist, very severely remarked: "Many other fantastical devices invented by poets are to be seen in the works of ancient writers. I do of purpose omit them as things unworthy of my recording or your receiving."

Apart from the coal, Mugwort itself was supposed to preserve travellers from fatigue, sunstroke, wild beasts, the evil eye, and evil spirits; and it must have been useful to know that if laid in the soles of the boots, it "will keep a man from weariness though he walk forty miles." Mugwort had also many medical uses, and in modern times the Japanese make Mox-a from it, which they use for cauterising.

Rue has the name for being a great digestive and help for the appetite; and the Romans thought it prevented drunkenness; the plant has a coarse, harsh smell, and a very bitter taste. There was an old belief that Rue grew best if stolen from someone's garden; it was in great request at one time, as eating the leaves was said to preserve the eyesight, and the juice of it used for the eyes cured "watery humours therein." Rue was often strewn in the dock at the Old Bailey Sessions, perhaps because it had always been thought to be very purifying. Country people use it now as medicine, sometimes eating it chopped up between pieces of bread and butter; its grows best on the sea coast, and it is quite common on the cliffs of Norfolk.

Rue was supposed to be a great antidote to witchcraft, and was used in spells, and at one time young girls made a wreath of Rue, Willow, and Crane's bill, which, while walking backwards to a tree they threw over their heads until it caught in the branches and was held there—each throw of the wreath that failed to catch in the tree meant another year of single life. According to an old "Book of Notable Things" (1575), "Rew hath a marvellous strength against wild Beasts," and one is advised "That Pigeons be not hunted nor killed of Cats; at the windows, or at every passage, and at every Pigeon's hole, hang or put little Branches of Rew."

Wormwood, Mugwort, and Rue have fallen a great deal into disuse, but perhaps this is not to be wondered at. We in England no longer live in deadly fear of wild beasts, the evil eye, and witchcraft, and, therefore, have no want of these homely yet powerful defences.

Centropogon Lucyanus.—Given the temperature of an intermediate house, or, failing that, the warm end of the greenhouse, this centropogon will flower throughout the winter and well on into the spring. It may be grown in pots with the loosely disposed branches secured to a stake, while it is also seen to particular advantage in a suspended pot or basket, as the somewhat weighty clusters of blossoms are brought immediately under notice from the fact that they cause the shoots to droop. The flowers are of a curved tubular shape, about a couple of inches long, and rich rosy carmine in colour. It is regarded as of garden origin, and is said to have been raised in 1856, but its parentage seems to be obscure. At all events, it is a most desirable subject where a display of flowers has to be kept up through the winter. Cuttings of the young shoots strike root readily in the spring and grow away freely afterwards. A liberal amount of leaf-mould in the potting compost is very beneficial to this centropogon.—W. T.

TWELVE GOOD CLIMBING ROSES.

A few weeks ago, in writing a short article for this magazine on the "Twelve Best Wichuraiana Roses," I found it very difficult to make up my mind which of the numerous beautiful Wichuraianas could justly claim thus to rank above their fellows. Probably no two people would agree on the subject. But at least the Wichuraianas, with perhaps the one exception of Gerbe Rose, are all suitable for the same purpose, they are rampant growers, perfectly hardy and can quickly cover any pergola, arch, or tall pillar to which they are trained. With the climbers, which are also autumnal flowering roses, this is not the case. Some, like Aimée Vibert, are as hardy and rampant as the Wichuraianas, others, in order to be seen in perfection, need the protection of a wall, while some again, though perfectly hardy, by reason of their more moderate growth, are not suitable for planting when large areas have to be quickly covered. In the following notes I have included some of each of these classes.

Climbing Aimee Vibert.

The hardiest and most rampant autumn-flowering climbing rose I know is the Noisette, Climbing Aimée Vibert. This is quite a veteran, having been brought out by Curtis in 1841, sometimes called the Seven Sisters' Rose. Everybody knows it, and how it will quickly cover a large space with its abundant green foliage, and produce both in summer and autumn its huge bunches of pure white flowers with which the pinkish buds are prettily intermingled. We have it growing on a tall wooden screen which separates a small rose garden from the croquet lawn; its neighbours are Aglaia and Crimson Rambler; it has done its work of covering the space allotted to it more quickly than either of these, strong growers as they are. It usually flowers about the beginning of July, lasting in bloom throughout that month, and flowering again in September. The most remarkable point about this climber, to my mind, is it magnificent foliage, so dense and beautifully arranged on the stem, and so nearly evergreen. I have a note made on November 22 last year to this effect: "After several nights of severe frost, the foliage of Aimée Vibert is as green and abundant as it was at mid-summer, in this respect surpassing almost all the climbers in the garden." The flowers, though effective on the plant, are, I think, a little disappointing when cut, the bunches are rather lumpy and the petals fall quickly.

Madame Alfred Carriere.

In this respect the hybrid Noisette Madame Alfred Carriere (Schwartz, 1879) is much better. The creamy-white flowers, tinted in the centre with flesh are produced throughout the summer and autumn, and, coming as they do, singly, or in loose bunches of two or three on erect, smooth stems, they lend themselves admirably to house decoration, their sweet fragrance adding to their charm for this purpose. Altogether, this rose appeals to me as a very lovable and gentle flower, never showy, but always refined and artistic. It makes a splendid standard, and, though not so rampant as Aimée Vibert, quickly grows up a tall pillar, and is fairly hardy. As I write on December 1, I can still find a few of its pale blossoms on a plant in the open. With so many good qualities it well deserves the description given of it in the N.R.S. catalogue as "the best hardy white climber."

ROSE MADAME ALFRED CARRIERE.

A finely developed specimen of this beautiful climbing rose at East Burnham Park.

Marechal Niel.

If Maréchal Niel were hardy, and able to produce in the open those glorious deep golden blooms it gives us under glass, there would be little difficulty in naming the best yellow climber. As it is, I think most rose growers would give the palm to the Noisette William Allen Richardson (Veuve Ducher, 1878), a rose too well known to need description.

The flowers lack form, and are variable in colour, but at their best they are a deeper and purer orange than can be found in any other rose; they are freely produced from June to October, and in a mild autumn much later. This variety grows well on pillar or wall, but not making strong basal shoots it requires some care in training to build up a good plant.

Reve d'Or.

Rêve d'Or (Noisette Ducher, 1869) is a rampant grower, which in many parts of England grows better and flowers more freely on a wall than in the open. In a genial climate it grows with extraordinary rapidity and luxuriance. A plant I saw this autumn in a Gloucestershire garden had in two years covered a big arch, and was thrusting forth its beautiful long sprays in every direction, evidently quite prepared to cover two or three more if allowed to do so. Here we grow Rêve d'Or on a south wall, and it would be a very cold inclement spring that would prevent it giving us a few of its golden blossoms on Derby Day. It flowers with marvellous freedom in this position, but has not made very strong growth; this may be on account of dryness at the roots. It does not flower as continuously as William Allen Richardson, but has a second crop in September.

Alister Stella Gray.

The third yellow rose that I would recommend is Alister Stella Gray, also a Noisette (Paul and Son, 1894). This rose is specially useful for its hardiness and for its freedom in early autumn, when so many climbers are not at their best; for, though it begins flowering in the early part of June, it reserves its best display for August and September. It has good foliage and a neat bush-like habit, which makes it particularly useful as a pillar; the flowers have a pleasant musklike fragrance, and are small but well shaped, pale buff in colour. At the top of a bank sloping to the south, on a naturally light soil, it has grown rather strong, but I have seen it make rapid growth in a garden in Leicestershire where the ordinary H.T.'s and Teas do not flourish as they do on our lighter, warmer soil. Some might think that Gloire de Dijon, or the best of its descendants, Madame Berard, should rank above Aliste Stella Gray. As regards the indeciduous flowers no doubt they would do so, but neither are such generally useful roses. They are apt to become very lank and leggy if grown on pillar or pergola, and if used for this purpose, need to be clothed at the bottom with some dwarfer variety.

Reine Olga de Wurtemburg.

So far the Noisettes have provided us with all our examples of good climbing roses. For reds and pinks we turn to the Hybrid Perpetuals and Hybrid Teas. The two best red, climbing autumnals for general use are, in my opinion, Reine Olga de Wurtemburg (Nabonnand, 1881) and Ards River, H.P. (A. Dickson and Sons, 1894). Reine Olga, with its bright rose-crimson flowers, makes a brilliant effect in early June, especially if grown on a wall. A plant of this variety I have in my mind has gone right to the top of an old-fashioned house, where it is very beautiful when in full bloom, making a fine background to a border of mixed flowers. It blooms again in September, and is almost evergreen.

Ards Rover.

The individual flowers of Ards Rover (A. Dickson and Sons, 1894) are much finer than those of Reine Olga, but they are not so numerous nor so brilliant. They are dark crimson, and are full and somewhat globular in form. It is a vigorous climber, and does well on arch, pillar, and even on a north wall. We had a plant growing on the north side of a thatched fruit shed, and the deep red flowers showed up very well on the pale straw-coloured thatched roof. If we include another red in our best dozen, it must be Francois Craisse, H.T. (Guillot, 1900). At its best it is a bright scarlet-crimson, and is one of the earliest of the H.T.'s to flower. It is surprising how seldom this rose is seen, the reason may be that flowering so early, its first bloom is over before any of the shows are held, and at its second flowering in September it is apt to lose its brilliancy of colour, when its chief merit has gone.

Climbing Papa Gontier.

One of the most beautiful climbing roses is Climbing Papa Gontier (Cherrier, 1904). Its rosy-pink flowers with large shell-like petals and its bright crimson buds never fail to catch the attention of the lover of roses. It makes very long rod-like shoots, and these should be trained well down, as it is likely to become very leggy. It does best on a south wall, where the warmth helps to ripen the wood. On a pillar it has a tendency to rush up very quickly and become bare at the base, and seems to lose its freedom of flowering.

The same may be said of that other fine Hybrid Tea Climbing Mrs. W. J. Grant (The E. S. Hill Co., 1899). Both this and Climbing Papa Gontier produce very much finer flowers with us than do their dwarf progenitors. In this garden one of the first joys of the rose year is to find a big bloom of Climbing Mrs. Grant on a south wall and this usually happens before May has passed into June.

Climbing Caroline Testout.

The next two pink climbers I would recommend are Climbing Caroline Testout (Pernet fils-Ducher , 1890) and Papillon (Nabonnand, 1882). These are excellent for forming pillars, though no doubt Papillon, being a Tea, would appreciate a wall where space can be given it. It is sufficient to say of Climbing Caroline that it grows with great vigour, and is able to produce as fine or even finer flowers than the popular dwarf variety of that name.

Papillon is an excellent climber, and unquestionably an ideal rose for a tall pillar; for though it goes up quickly it does not forget in its desire to reach the top that the most important thing for a pillar rose, as for any other kind of pillar, is a good broad base, and so it produces plenty of shoots on its upward way.

Papillon.

The past hot summer suited Papillon admirably. It was conspicuous in many of the decorative exhibits at the N.R.S. Autumn Rose Show, and a tall vase filled with long sprays of its coppery-pink flowers at the Crystal Palace in late September was one of the most effective exhibits of the show. My number is now complete, but, in addition to many beautiful roses, such as Lady Waterlow, Gruss an Teplitz, Gustave Regis, etc., which, though usually grown as bushes are very effective as climbers on low walls or as dwarf pillars.

White Lady.

SOME INTERESTING VIBURNUMS.

The last ten or twelve years has added a considerable number of showy and interesting viburnums to the list of shrubs suitable for outdoor culture, for although some of them had been known of, from herbarium specimens, at an earlier date, they had not previously been seen in cultivation in British gardens. Though they are of such recent introduction, however, several have already found for themselves a prominent place, which says a great deal in their favour, for several of our best garden shrubs are found amongst the older viburnums. As is the case with the majority of the well-known viburnums, the newer kinds thrive satisfactorily in almost any good garden soil, that of a loamy character being suitable to most, whilst a little peat added to sandy soil suits the remainder. It most cases cuttings of half-ripe wood, inserted in pots of sandy soil indoors, in July or August, form a good means of increase, but it is also possible to propagate many sorts from seeds, which are matured most years.

V. buddleifolia is a Chinese shrub, six feet or so high, which was sent to Messrs. Veitch from Mr. E. H. Wilson when collecting in Hupeh. He reports it as being found at altitudes varying from 3,000 to 5,000 feet. Its leaves, as the name implies, bear a striking resemblance to those of some of the buddleias, and are not unlike those of B. variabilis, although smaller. They are lance-shaped, and up to six inches in length, and one to one and a-half inches wide, the margins being toothed. The undersurface of the leaves and the young wood are covered with a dense grey pubescence, whilst the upper sides of the leaves are also grey and hairy. The white flowers are borne in dense terminal heads.

V. Carlesi.—It is about nine years since this charming species was introduced, and some three or four years later the earliest flowers were produced in this country. Collected in Corea by Mr. W. R. Carles, about 1885, it was named in his honour, and prior to its introduction to this country it was cultivated in Japan. When first introduced to England it came with the reputation of being a tender shrub, but after nine years' experience of it in an open border, it has proved to be as hardy as other new kinds, though it appreciates a little shelter from cold winds. Of rather slow growth, it forms a compact little bush one and a-half to two and a-half feet high, with rounded, greyish, dentate leaves, two inches or so across. Flower buds are formed during one summer for the next year's flowers, and they commence to expand late in April or early in May. In the bud stage they are pink, but on expanding they are white, their opening being accompanied by a delicious perfume. Fully expanded inflorescences may be from two to three inches across. This species thrives best in light soil, into which a little peat has been dug.

V. Davidi.—This species appears to have been first brought to notice by Father David, who collected it in Mupin in April, 1869. It was named by Franchet, with many more of David's plants, in Pl. David, ii., p. 69. Many years later Wilson collected it and sent home seeds. The latter traveller found it as a shrub, one or two feet high, on mountains at an altitude of 8,400 feet. It differs from many of the viburnums by having almost glabrous leaves. These are four to six inches long, and one and three-quarters to two and a-half inches wide, with serrate margins and acuminate apices. They are distinct by reason of three well-defined veins, the two outer ones forming an ellipse about a quarter of an inch from the margins. The small white flowers are borne in dense terminal heads, and they are succeeded by purplish fruit.

V. Henryi.—This appears to be very variable, for travellers have recorded it as a trailing plant, and again as a bush or small tree, from ten to twenty feet high. The slender branches have greyish bark when young, and purplish when older, and they are clothed with yellowish-green, oblong, evergreen leaves, which have serrate margins. Small white or yellowish flowers are borne in terminal panicles, which may be up to four or five inches long. It has been recorded from Hupeh, Szechuan, S. Washau, and other districts.

V. rhytidophyllum.—Much has been written about this wonderful evergreen species of late years, and it is certainly one of the most remarkable of the many Chinese introductions. Growing naturally to a height of ten feet, it is conspicuous by reason of its large oblong leaves, which may be anything up to nine inches long, and two and a-half inches or more wide. The upper surface is yellowish-green, and curiously wrinkled, the undersurface and the young wood being thickly covered with brownish-yellow, star-shaped hairs. The cream-coloured flowers appear in large flattened heads, sometimes as much as nine inches in diameter, and they are succeeded by red and black berries.

V. utile.—This is another handsome Chinese species, which forms a bush up to five feet in height. The oval leaves are from one to three inches long, silvery, and tomentose below, and dark green above. White flowers are borne freely in rounded heads two to three inches in diameter, during early summer. It is easily one of the most decorative kinds, and one which ought to be widely grown in the near future.

W. D.

"CARNATIONS, PICOTEES, AND PINKS" will tell you plainly how to propagate and grow these favourite flowers to perfection. The work is freely illustrated with plates of leading varieties, and explanatory diagrams as to layering, taking cuttings, fertilising blooms, etc. Price 2s. 6d. net. by post, in box, 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

A VALUABLE LATE WHITE GRAPE.

When gardener to Lady Hutt at Appley Towers, Mr. Miles devoted some part of his attention to raising new grapes, and was so far successful in this part of his activities as to obtain two varieties of so high an order of merit that first-class certificates were conferred upon them by the Royal Horticultural Society. One of these was named Appley Towers, after the place of its origin, and the other was dedicated to Lady Hutt, and both varieties, if not grown so largely as their merits would warrant, have maintained their places in gardens in which grapes are grown somewhat largely under glass.

The first of these two varieties to be submitted to public notice was Appley Towers, of which three excellent clusters were shown by Mr. Miles at one of the several meetings held by the Royal Horticultural Society in the autumn of 1899. This variety belongs to the black section, and has medium-sized bunches and berries, and the latter have a thick skin with fine bloom and the flesh is firm and richly flavoured. It has the merit of setting freely, and the fruit remains in excellent condition until quite late in the year. It is described as having been raised from a cross effected between Gros Colmar and Alicante, the first-named being the seed-bearing parent.

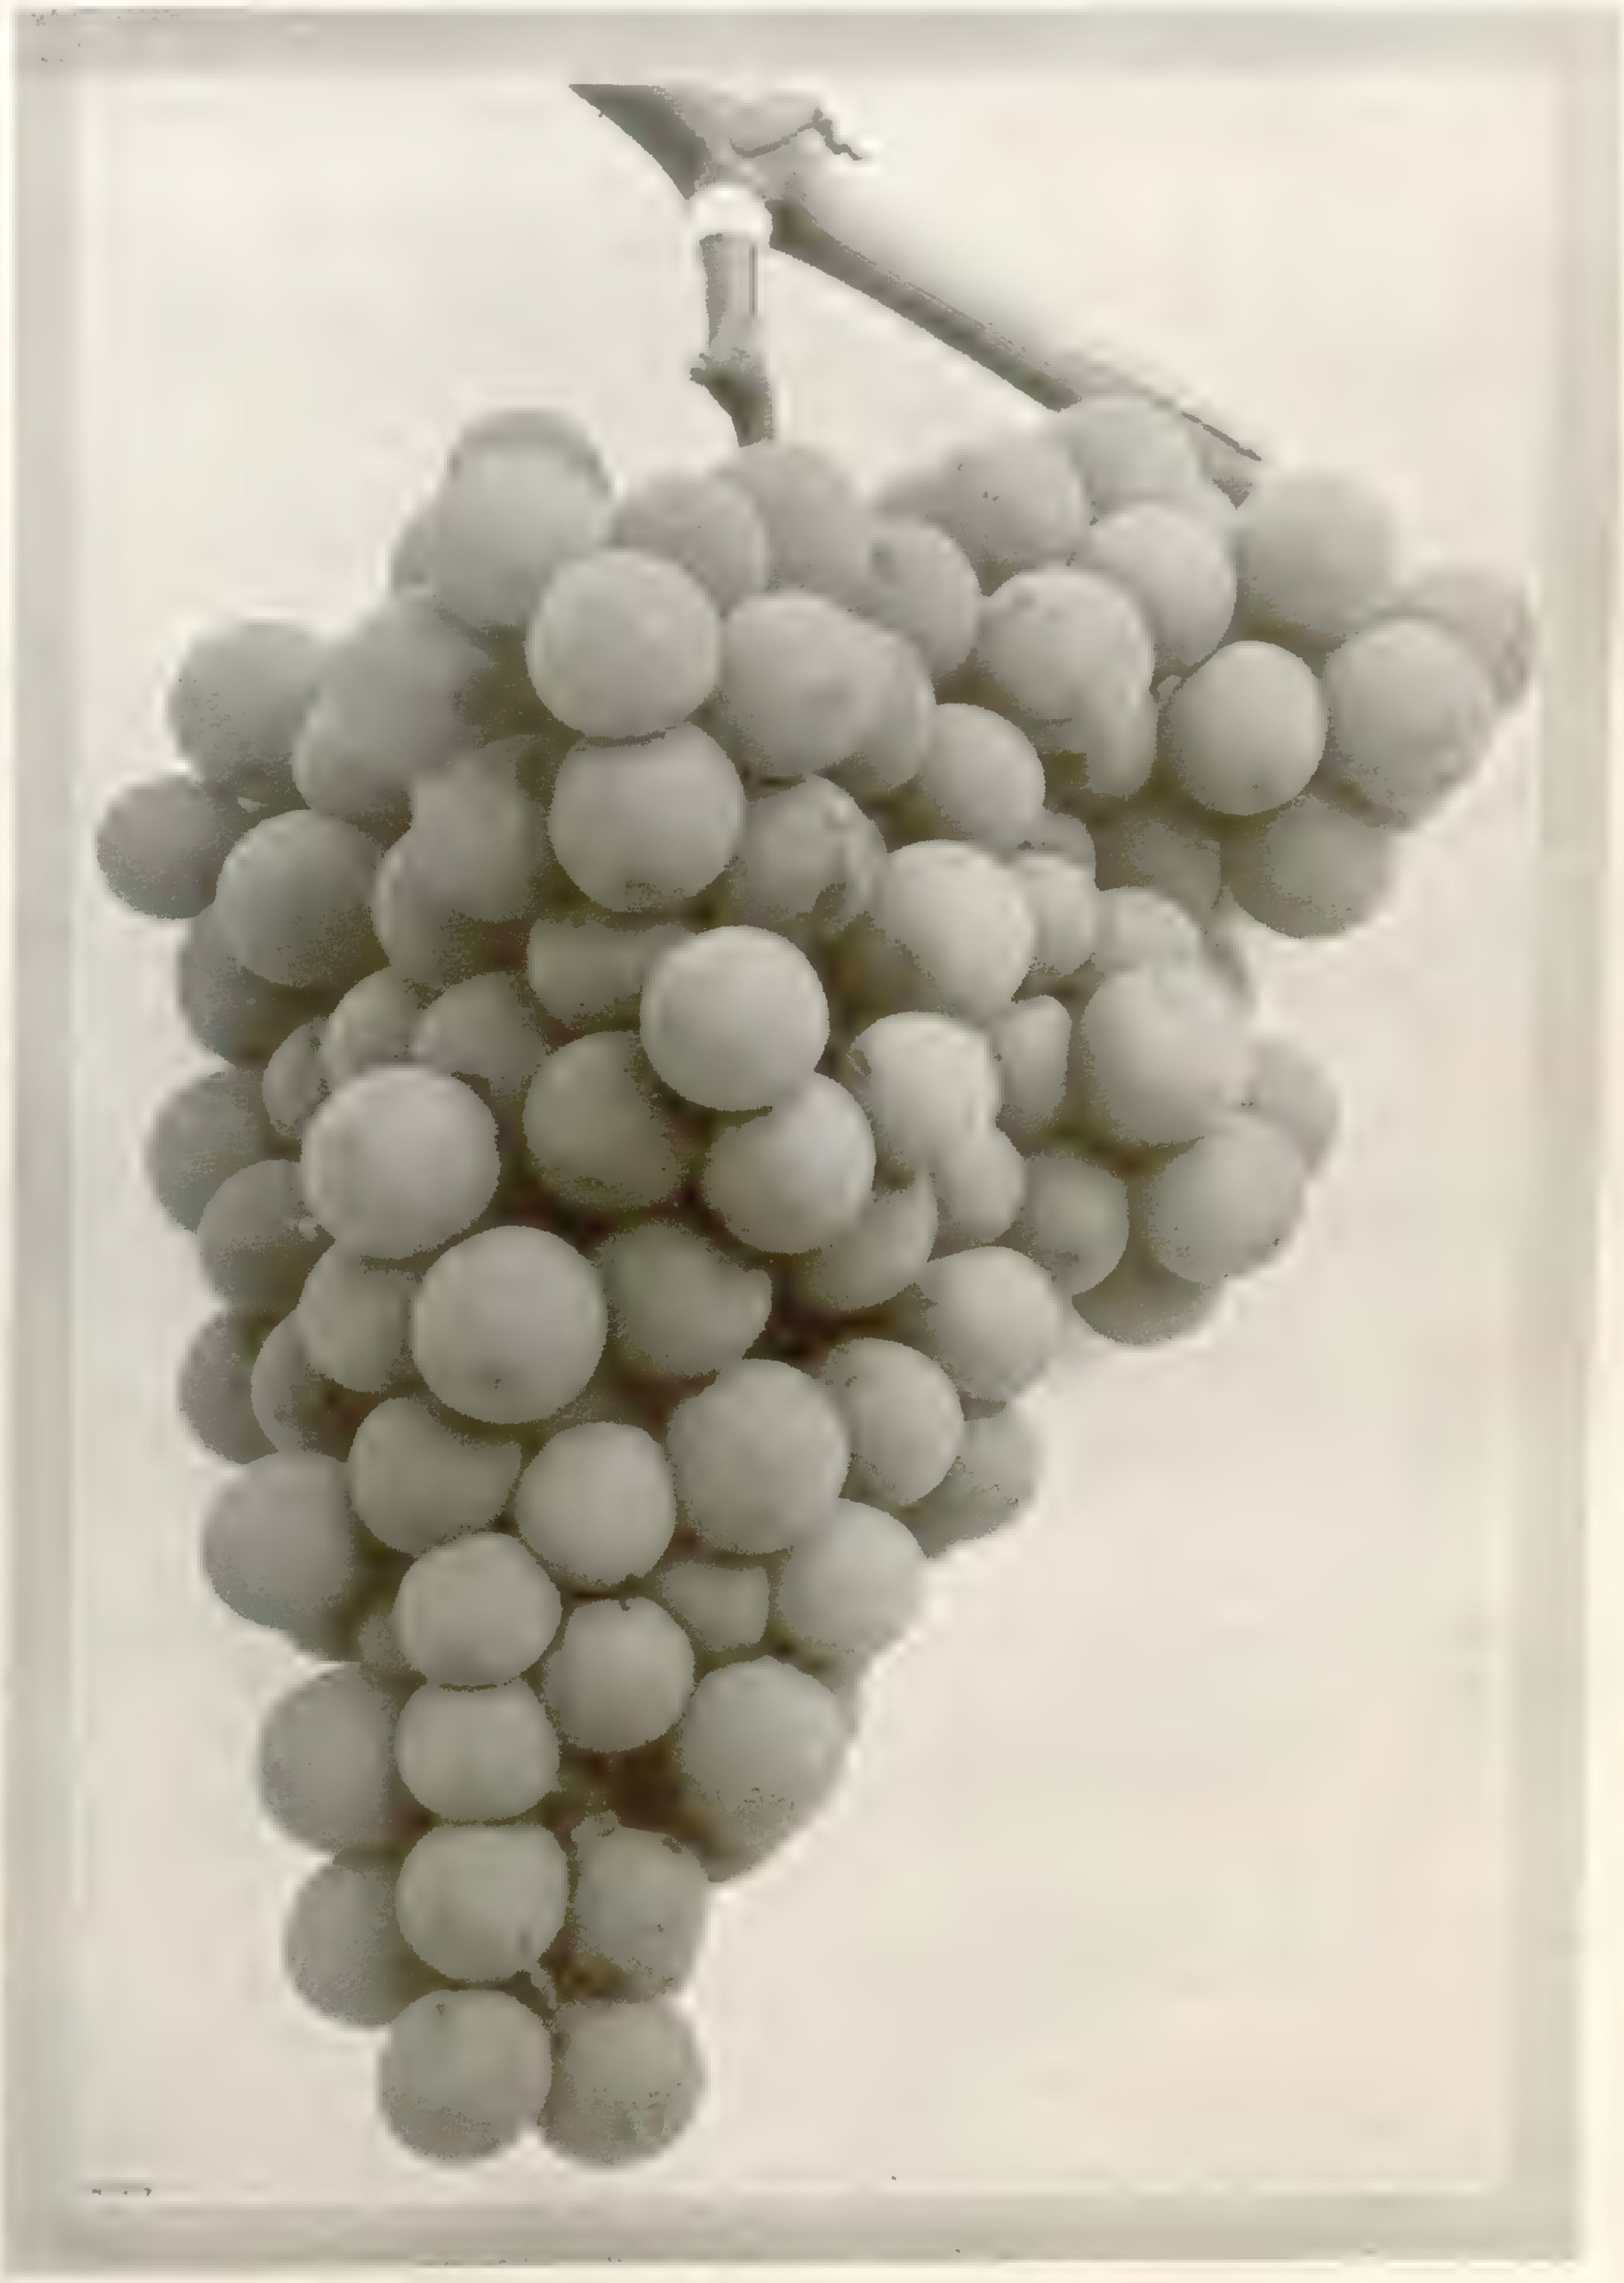
The origin of the foregoing variety is of special interest from the fact that Lady Hutt, which was shown at a meeting of the Royal Horticultural Society in the autumn of the following year, has the same parentage. Whether they were raised from seeds taken from the same berry, or, indeed, from the same bunch is not recorded. All the readily accessible information relating to the parentage is to the effect that they were raised from Gros Colmar, the flowers of which had been fertilised with pollen of Alicante. Lady Hutt belongs to the white section, and in appearance the bunches have a resemblance to the sweetwaters, with which the late Mr. Barron classified it. The bunches are of medium size, shapely, and decidedly attractive. The berries also are of medium size, and of a bright golden hue, and the flesh is firm and rich in flavour. It is described in "Vines and Their Culture" as a midseason grape, but, as the fruit remains in perfection until the end of the year, its proper place is among the late varieties. The fruit is available for the table early in the autumn, but keeps well until the end of December, and may be described as the best white grape, excepting Muscat of Alexandria, of its season.

Lady Hutt has no peculiarities that render it specially difficult to produce full crops of high quality, and should be in gardens from which supplies of late grapes are required. If Muscat of Alexandria is grown Lady Hutt will make an agreeable change occasionally, and if there are no provisions for the cultivation of Muscats Lady Hutt will be a very good substitute. At Somerleyton Hall the last-named is most successfully grown in the same structure as Lady Downes, and Mr. Hanson, the head gardener, regards it with much favour, and anyone who has seen the fine crop we had the opportunity of seeing a few days ago will not be surprised that he should do so. In his practice, Mr .Hanson allows a rather greater extension of the laterals than is deemed necessary in the case of the other grapes generally grown, and he somewhat restricts the space provided for the roots. With reference to these two points, it may be suggested that those who have failed to obtain a full measure of success in the cultivation of this fine grape will be well advised in adopting the practice which has given such good results in the Somerleyton Gardens.

BERRY-BEARING SHRUBS FOR XMAS DECORATIONS.

There is usually a charm about shrubs that carry their fruit through the winter, whether the berries are black, white, red, or yellow, though those with red berries are most attractive. Unfortunately, we have not many species that grow sufficiently large to make bold specimens for the lawns, though there are ample of smaller dimensions, useful as pot plants, or for grouping.

Undoubtedly the best of all shrubs for large specimens is the holly, of which we have many varieties of the Ilex aquifolium, all of which are more or less beautiful, but for these to fruit profusely they must be given an open situation, and be allowed to grow naturally, as it is on the previous year's shoots that the fruit are borne. Where the trees are grown in an open sunny position they do not assume so dense a habit, and as the shoots are farther apart the light and air are able to penetrate among the branches, the young wood is better ripened and the crop of fruit is improved. In addition to the varieties with green or variegated foliage and red fruit, we have others carrying yellow berries, and, though less attractive, they are very beautiful when laden with their golden fruits. In addition to these there are several kinds of ilex that are, as a rule, but little known to gardeners, and one of the most attractive that I am acquainted with is I. latifolia. Though introduced into this country as far back as 1840, it is seldom met with. Yet it is perfectly hardy. When the tree has attained a large size, it assumes a loose, upright habit, making shoots each season from a foot to fifteen inches in length. The flower stems are very short, so that the berries cling close to the shoots. The foliage is very large, resembling that of a laurel except for the spines on the points of the leaves.



GRAPE LADY HUTT.

A late white variety of great excellence.

Most people are well acquainted with the aucubas, but not everyone has seen the shoots covered with clusters of large red berries; the reason is that there are male and female plants, and unless some of each are grown in close proximity to one another, so that the pollen may be scattered by the wind there will be no fruits. Birds, as a rule, do not touch the berries, and this being the case, the bushes are attractive until the spring, when the fruit falls off. There are several varieties, some having green and others spotted foliage. Small plants grown in pots are very attractive for indoor decorations during winter.

Skimmias, when grown in pots, make very neat, showy plants for either the cool conservatory or indoors, as they fruit so freely even when quite small. They are quite hardy, but when grown for indoor decoration should have the protection of a cold frame, so that they may be lifted when required. S. oblata has large green leaves, while the foliage of S. japonica is small and very neat. A peaty soil suits them best. Pernettyas make neat little plants for indoor decorations, fruiting most profusely even in a small state. Though these will grow to fair-sized bushes if allowed to ramble, yet when its roots are confined in poor soil it makes rather slow growth. The fruits vary considerably in colour on different plants.

We are accustomed to see Euonymus radicans grown as an edging plant to small beds, but those who have not tried it for covering walls or pillars, have no idea of its beauty, and they would be astonished at its growth. The foliage, when the shoots are allowed to ramble at will, attain about three times the dimensions of those on small, low plants, and when once the roots have taken good hold of the soil, growth is most luxuriant, being two or three feet in length in one season, and in the axils of the leaves, on the previous year's growths, there will be produced clusters of triangular red berries. In some seasons these are in such abundance that they look like a lot of coral beads among the large silvery foliage. The deciduous Euonymus europæus, which is often found growing in the hedge-rows, produces its clusters of berries in this manner. The common privet is so well known that it requires no description; its terminal spikes of black berries are very attractive, and are often used with effect at Christmas. But it is to the Chinese and Japanese species that we most look for special effect, as some of these are most attractive, especially when grown as standards. P. sinensis floribundum, P. ovalifolium elegantissimum, P. Quihoni, and others make excellent subjects for this purpose, and when grown on stems from four to six feet high, are very useful for grouping with other plants.

There are many other deciduous shrubs that produce berries that do not ripen until late in the season or are not palatable to the tastes of birds; among these we may mention the Snowberry (Symphoricarpus racemosus), S. vulgaris variegatus, and some of the viburnums and berberries. The latter produce their fruit in pendant clusters. There are yet others, but space forbids me mentioning more than the tree ivies and the evergreen thorns, many of which are very attractive.

H. C. PRINSEP.

THE BEST WICHURAIANA ROSES.

Your correspondent "White Lady" alludes at page 776 to Excelsa, a remark I can confirm as to its being a stronger grower and a free bloomer. With me it made growth 12ft. high direct from the base and flowered profusely. It was one of the best varieties I had, with flowers of a bright colour, to withstand the extraordinary sun heat we experienced last summer. I look upon this rose as one of the best of the Wichuraiana class. Minnehaha with me is quite distinct from Dorothy Perkins, and it has the merit of displaying its blossoms in an open panicle which is at once graceful and imposing. For pillars it is one of the finest. Gardenia cannot be omitted from even the smallest selection. It is the first rose of its class to produce its blooms, and it is the latest in flowering, its yellow buds are most charming, as also are its flowers, which are white when fully expanded. These, coupled with the dark-green foliage and vigorous growth, renders it one of the finest pillar plants we have, far outclassing Jersey Beauty, which, although pleasing when in flower, is altogether too fleeting.

Madame Alice Garnier has small pink flowers on a yellowish ground in clusters not too thickly studded. The foliage is especially dark green, emphasising the blossoms above. This is a Wichuraiana climber. I can strongly recommend Paul Transon, rosy-pink, free, and opening its flowers early

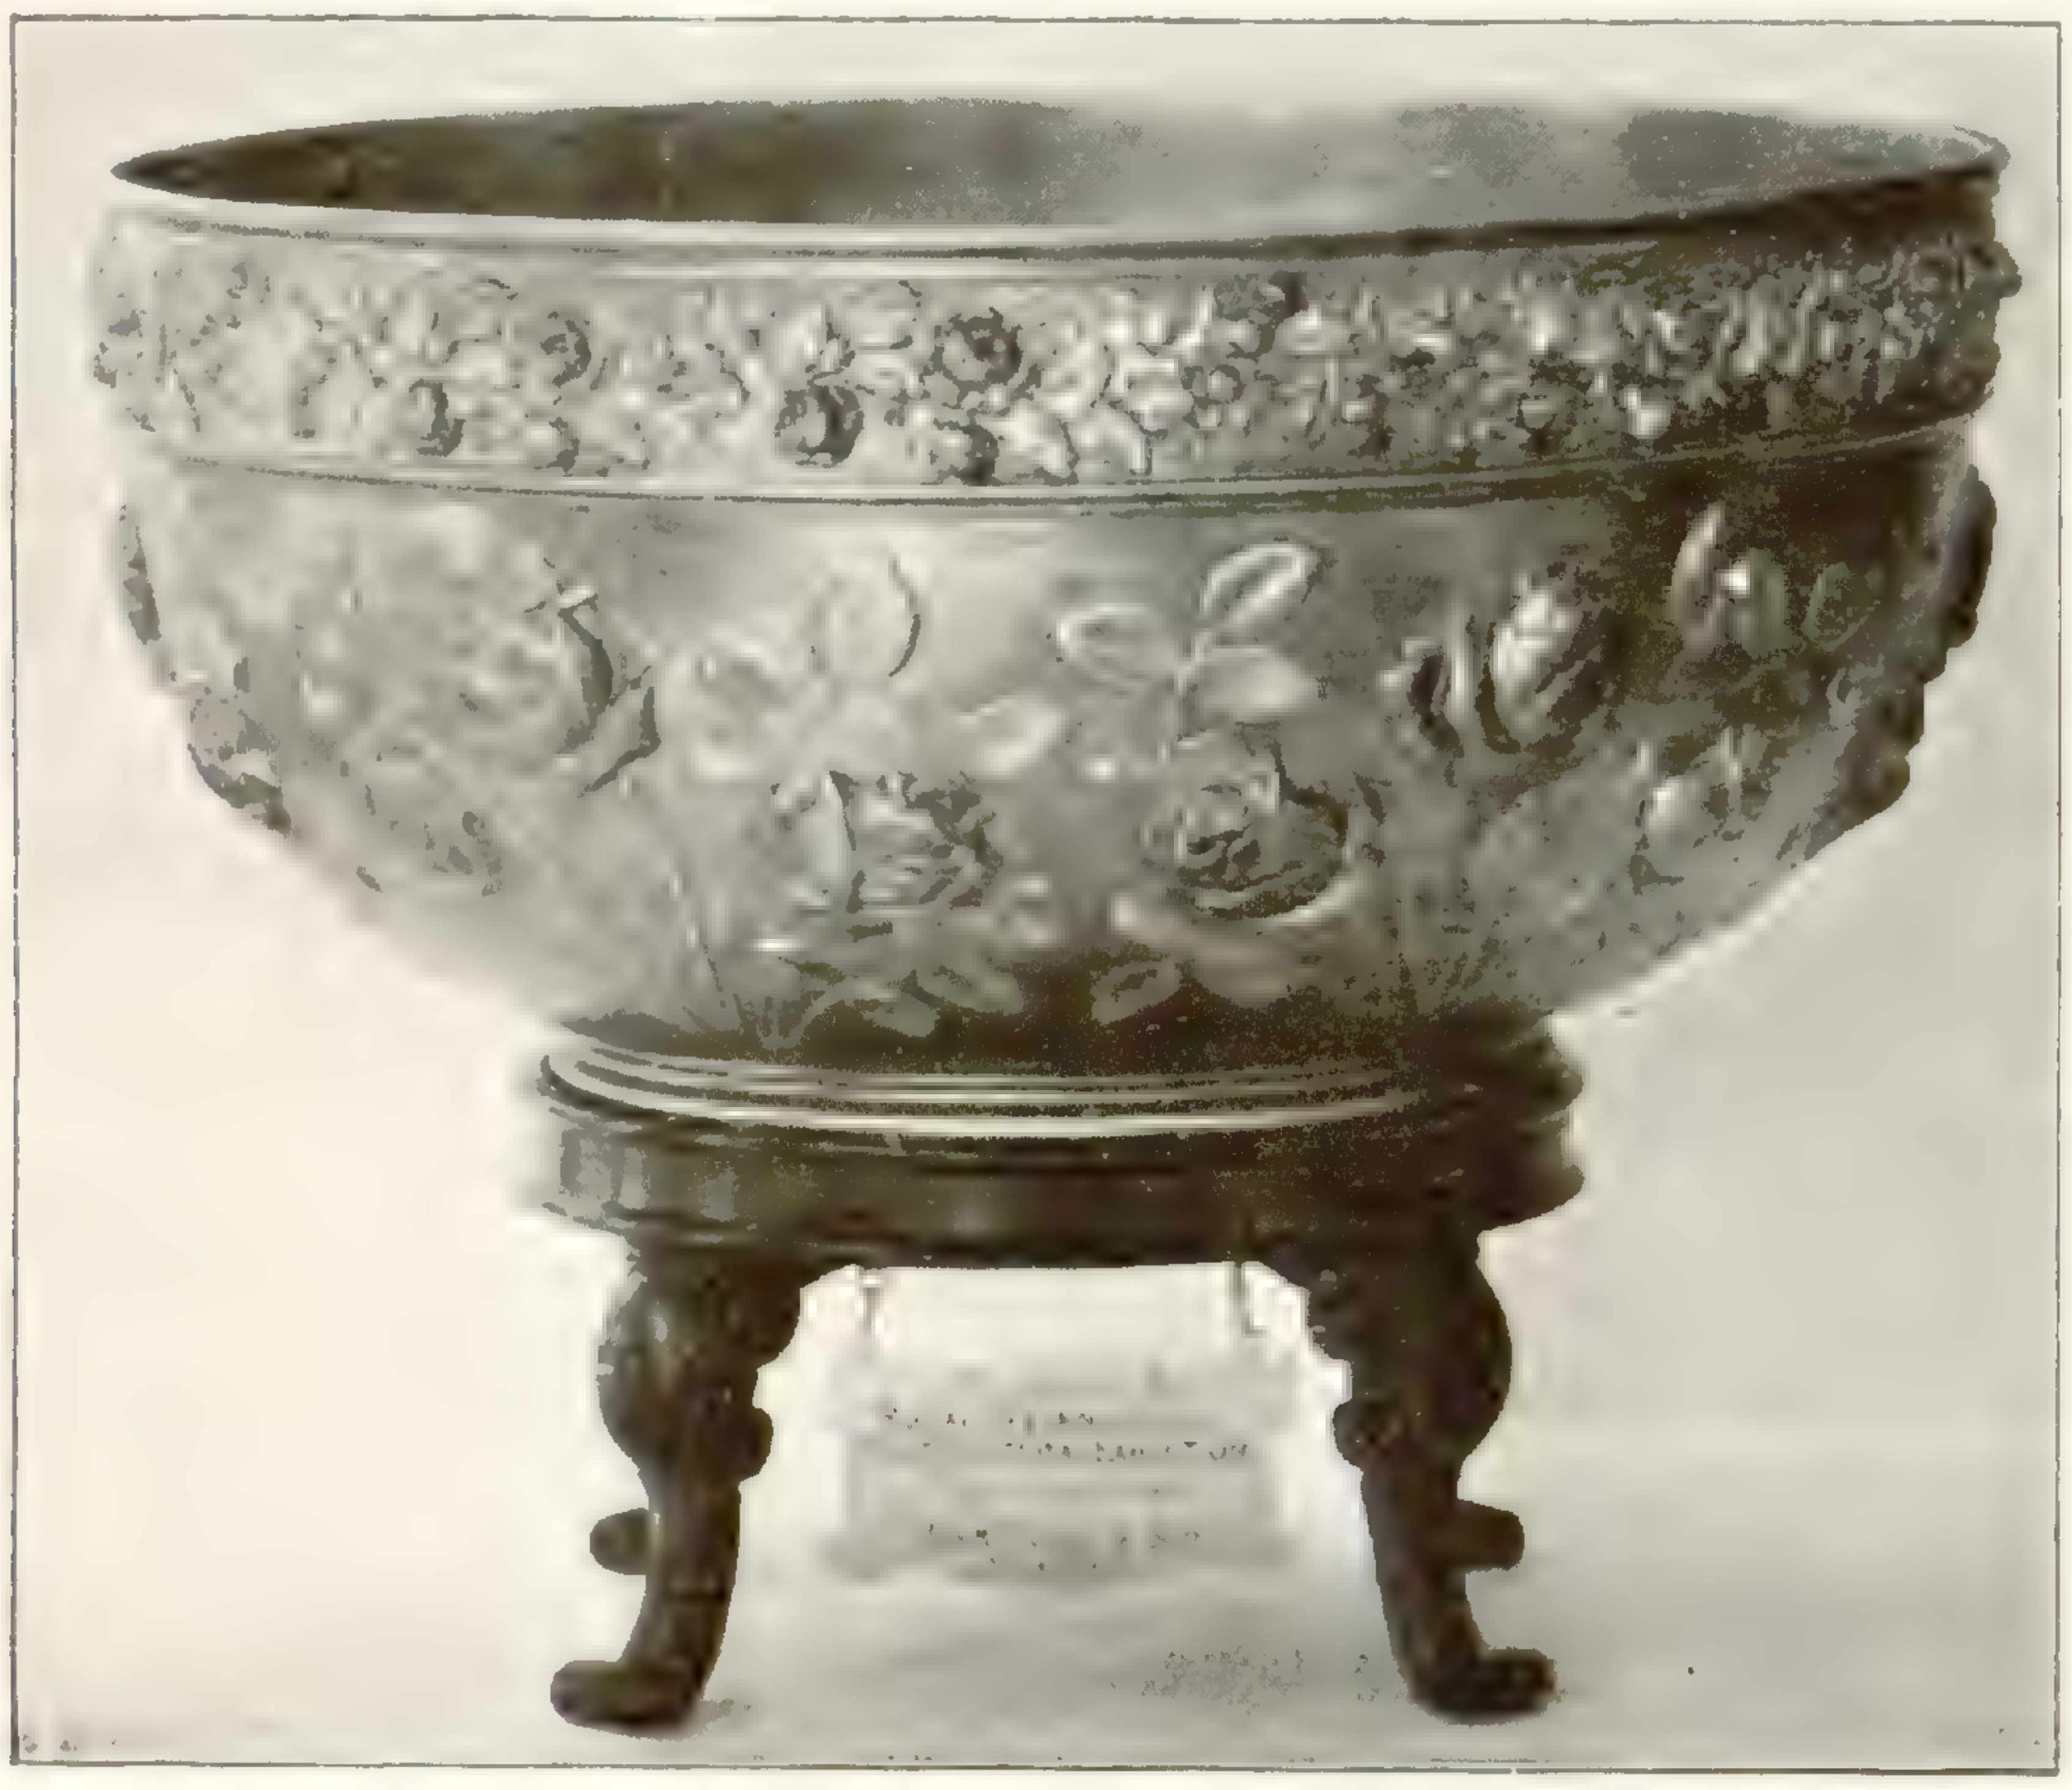
E. M.

THE CLAY ROSE-BOWL.

The magnificent silver-gilt rose-bowl which we herewith illustrate has been presented to the Royal International Horticultural Exhibition, 1912, by Messrs. Clay and Son. It will be awarded to the best exhibit of roses at the exhibition in May next.

The following description is supplied by the manufacturers, Messrs. Elkington and Co., Lim., 22, Regent Street, London, S.W. The bowl is silver-gilt, with roses and a floral band chased repoussé, in high relief, and gilt in natural colours. The bowl weighs 80oz., measures 13in. across; its height, without pedestal, is 6½in., with pedestal 10in.

The inscription, which is engraved upon a silver-gilt plate attached to the pedestal, reads: "Presented to the Royal International Horticultural Exhibition, May 22 to 30, 1912, by Messrs. Clay and Son, Stratford, London, E." It is also proposed to have a detailed inscription engraved within the bowl itself.



THE "CLAY" ROSE BOWL.

To be awarded for the best exhibit of roses at the Royal International Horticultural Exhibition of 1912; presented by Messrs. Clay and Son, Stratford.

ROCK GARDEN JOTTINGS.

MOSSY SAXIFRAGES IN WINTER.

The mossy saxifrages may be said to have two seasons of special beauty. In spring they are exquisite with their sheets of white or pink flowers, and in late autumn and winter they are lovely with their mounds of green of various shades. Some of them are like mounds of moss, and show how aptly they have been named "mossy saxifrages."

Variegated-leaved Arabises.

This is shared by the variegated-leaved arabises, especially by those of the class of Arabis albida and A. alpina. In the first we have the golden and silver variegated forms, which are very lovely just now, and which give good patches of brightness to the rockeries. In the case of the second there is now a fine variegated-leaved variety of the well-known double arabis. This appears to be a little less hardy than the green-leaved one. Then there is Arabis lucida variegata, poor in flower, but in a cool soil giving fine rosettes of variegated leaves. A. procurrens variegata is not of so much account as a garden plant.

Silvery-leaved Plants.

Quite a good appearance is also made by some of the plants with silvery or white leaves, which we appreciate now even more than at other times, when white flowers are plentiful. At present blossoms of any kind are few and far between, and we enjoy a little colour of any kind. In winter some of the cerastiums, such as C. biebersteiniana and C. tomentosum, are fine with sheets of white. Santolina incana is also very nice, and gives a mass of silvery leaves. But I am not writing this to give a list of white and silver-leaved plants, but to bring before the notice of the reader the value of such plants at this season.

Erica carnea.

Quite pretty, also, at the present time, are the bushes of Erica carnea, even though they are not fully in flower. They are pretty little bushes of perfect greenery, all thick-set with flower buds. I think the white variety, E. carnea alba, is the prettier just now, as its white buds are spangled all over the plants almost as thickly as the stars in the Milky Way. I expect to have these heaths, the flesh-coloured and the white, in bloom before the snowdrops this season.

Yuccas.

Yuccas also please us greatly in winter. Though not in bloom, of course, they are effective, as they stand with their handsome growths and fine leaves. I have a goodly number here, and it is hard to say which is the finest. Gloriosa is grand, so is recurva; and I like some of the newer ones, such as Vomerense and Saundersi, Italian hybrids. Albella is also a pretty one for winter, but there is none so good for general garden purposes as that known in gardens as Y. filamentosa, which has hair-like filaments along the margins of the leaves. It is more free-flowering than any one I know, and is thus a good winter and summer plant. Such subjects as this give a character to the large rockery which it requires.

New Zealand Veronicas.

It is rather pleasant to see how these are growing in favour. For rockeries they are capital subjects, as a whole, although some are rather too tall for the small place. Pinguifolia is very nice; Bidwilli is a gem for the rockery; Lindsayi makes a bold bush with pink flowers; and such as cupressoides and Hectori are quite valuable subjects in every way. They are, in general, good winter subjects.

The Soldanellas.

These are now obtaining the shelter of sheets of glass for the winter months. This is not because they are injured in their foliage by the winter frost, snow, or rain, but because they bloom more freely if so sheltered and kept dry overhead. I have always a lingering impression that a special place might be made for the soldanellas, where they might receive plenty of water from the time they come into flower until, say, September, when they might be kept dry, or nearly so, for the rest of the time. But the sheet of glass is a good substitute for more natural conditions. It is interesting to think that these plants flower through the snow, as we would hardly expect such dainty and delicate-looking bells to stand such experiences.

Cobweb Houseleeks.

Practically all of these want the same consideration shown them in the way of winter protection from rain. On a wall planted in such a way that the rain cannot fall on the cobwebby tops, they will do very well as a rule; but in some places they also require this sheet of glass protection. They do not generally run into big clumps, and are all the easier covered with a piece of glass. A piece such as is used for a half-plate camera plate will do for a fair sized plant, and even a quarter-plate one will be big enough for a plant bought from the nurseries this year. Sempervivum arachnoideum is a long time of making a big piece, and S. Laggeri is much more rapid-growing with its bigger rosettes.

S. Arnott.

Dumfries.

APPLE NORFOLK BEAUTY.

I was glad to see Mr. Day speak so favourably of this apple on page 755. Since its introduction I have been a strong advocate in its favour, and hold the opinion that it will oust Warner's King from its present position, as this apple has so much deteriorated during recent years. Its constitution appears to have degenerated of late years, and this failing has been noticed in Kent as elsewhere. Mr. Day describes Norfolk Beauty as in season from September to Christmas. Here, in the South, it is purely an October apple. It seems strange that its keeping qualities have so altered, for when I first saw it the fruit kept soundly until the end of January.

The tree is of free growth, and to get good crops early an extensive system of pruning should be practised; close cutting back induces vigorous growth. A good way to obtain a full crop of fruits early is to put several grafts on rather a tall tree, and after the first pruning allow the shoots to extend, thus forming a weeping head of great beauty and usefulness.

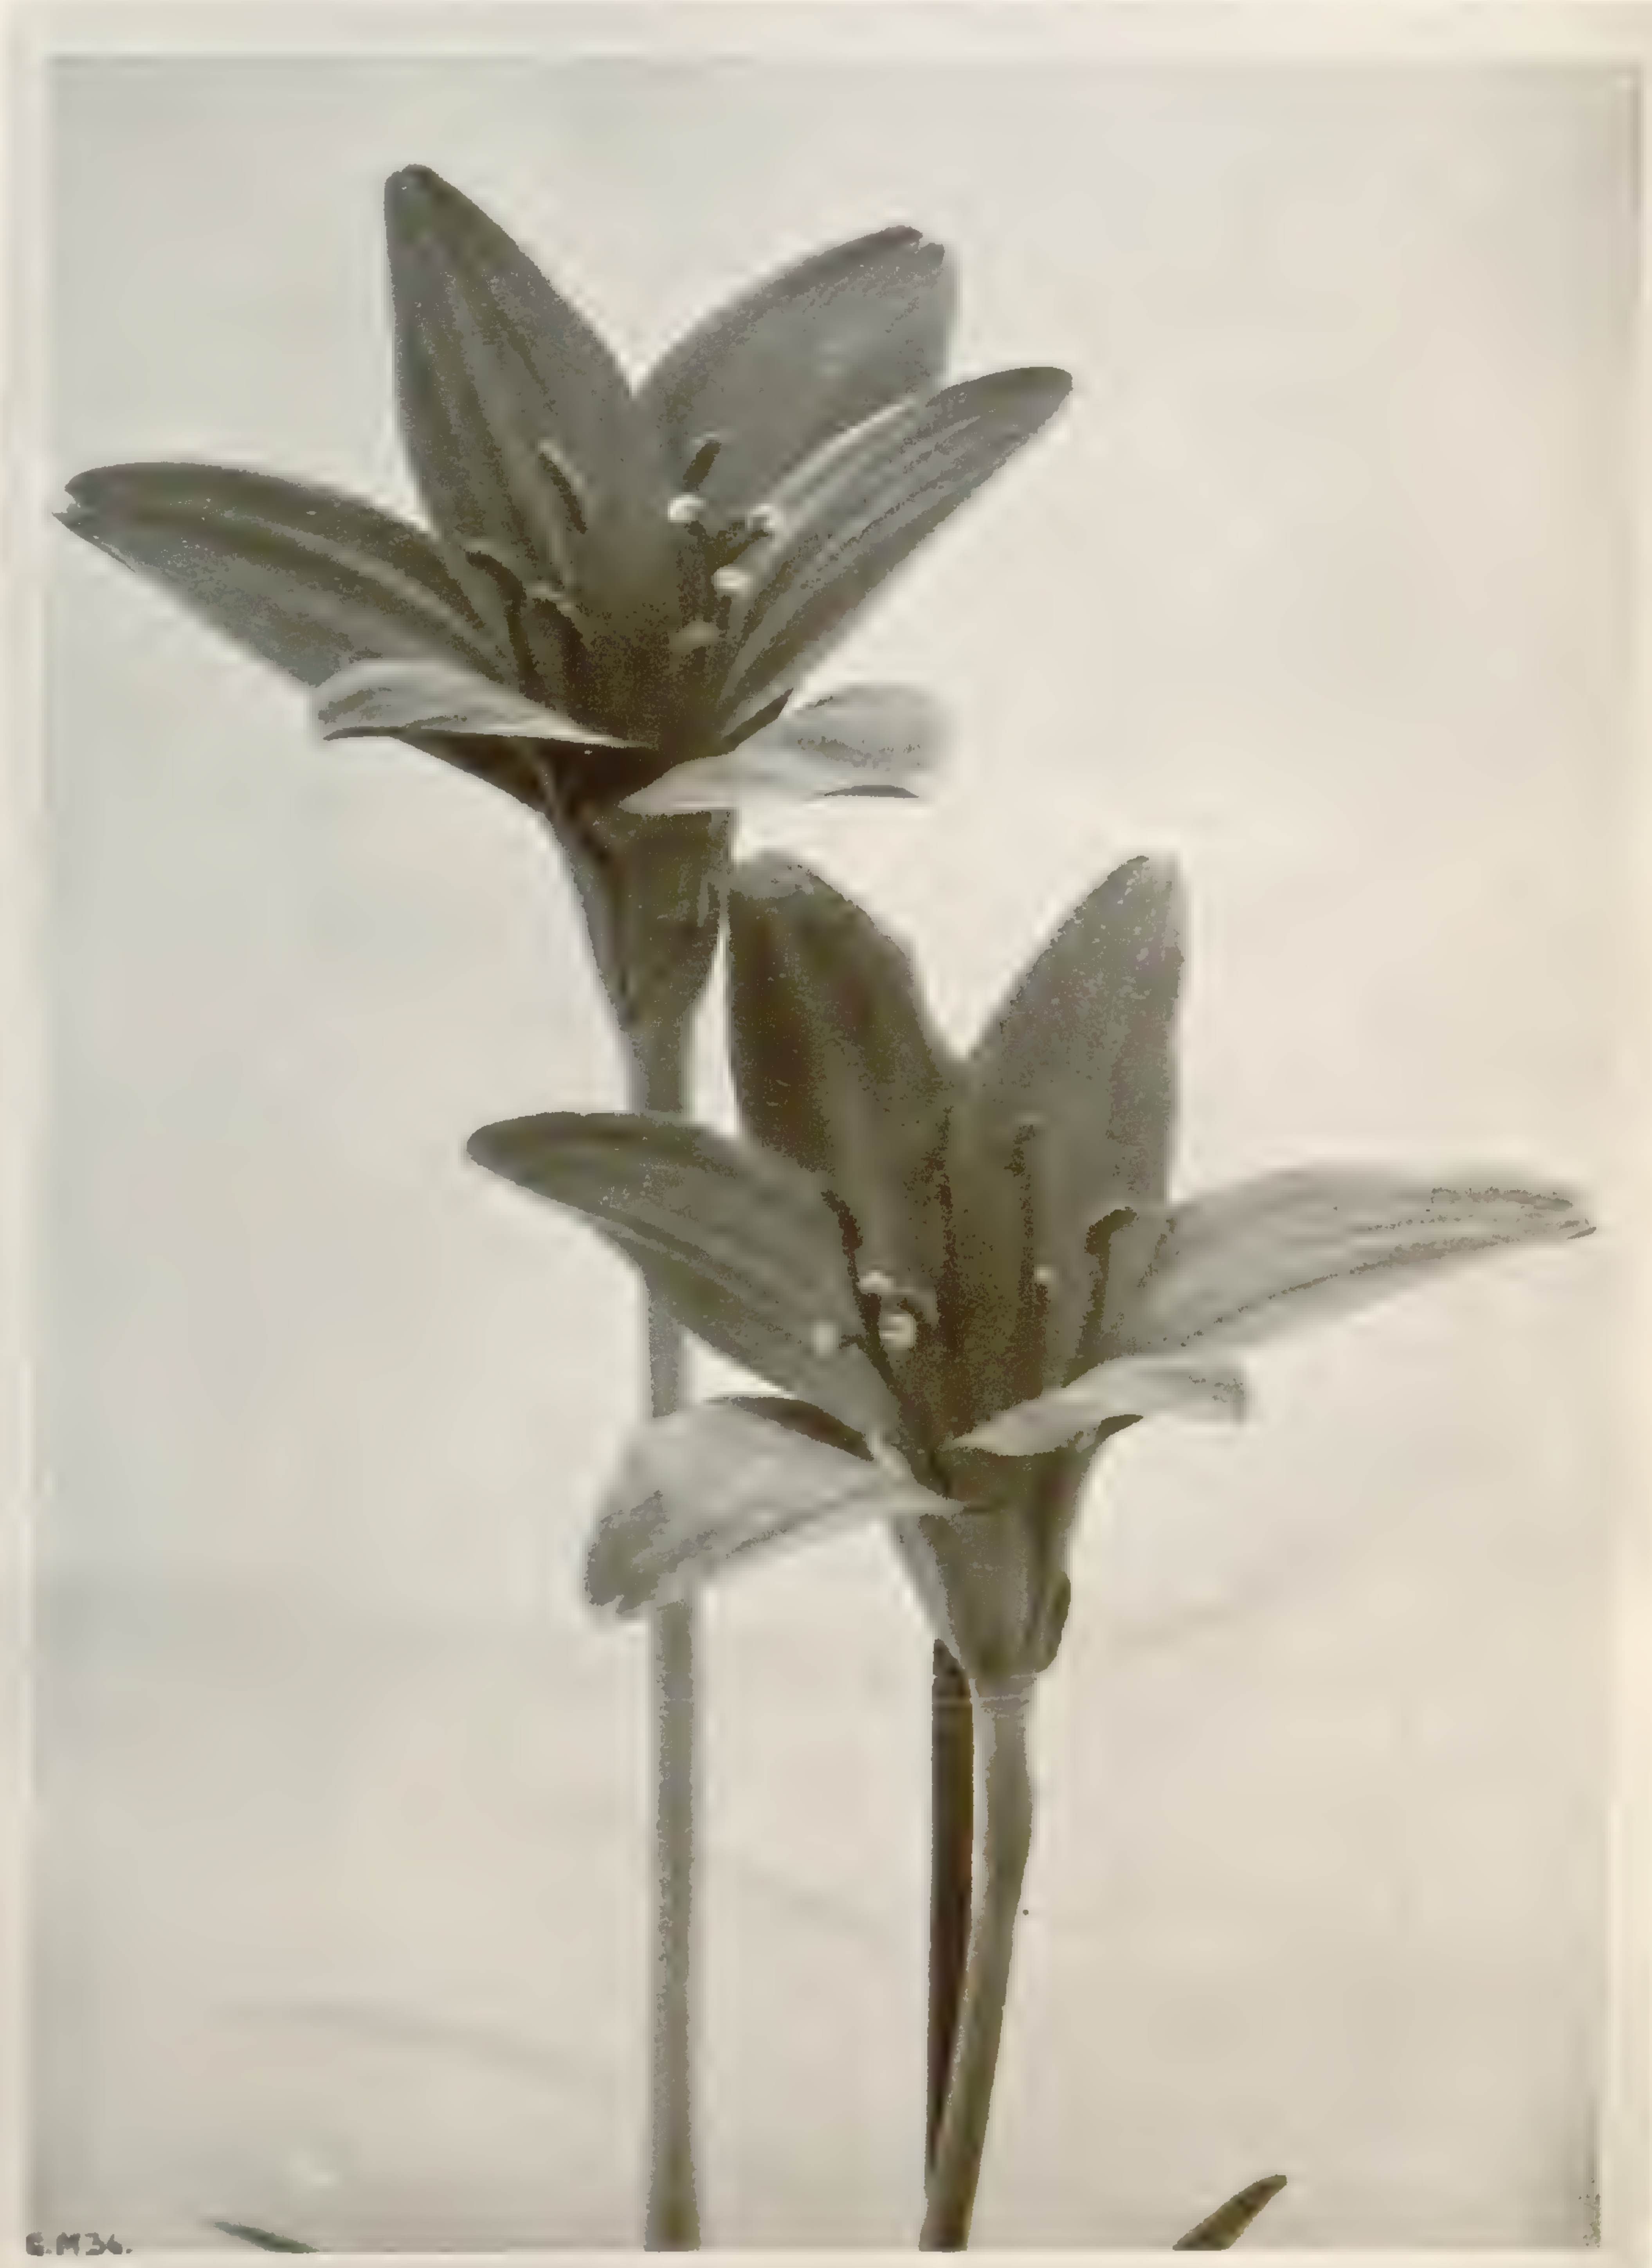
E. Molyneux.

NEW PLANTS, ETC.

◆

CYPRIPEDIUM DRACO WESTONBIRT VAR.

This fine form of a large and bold hybrid between C. insigne Harefield Hall and C. Euryades was figured on p. 913 of our issue of December 9. The dorsal sepal is white and green, freely and heavily spotted with bright purple; the petals are green shaded with brown, and the lip is of similar colour, but paler shade. A.M., R.H.S., December 5. Lieut.-Colonel Sir George Halford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.



ZEPHYRANTHES AUREA.

A beautiful golden yellow. Peruvian bulbous plant. F.C.C., R.H.S., December 5. Sir Trevor Lawrence, Bart. (gardener, Mr. W. Bain), Burford Lodge, Dorking.

ZEPHYRANTHES AUREA.

This is by no means a new bulbous plant, but, on the other hand, it is by no means common in gardens, and doubtless the fine condition in which it was shown at Westminster recently was due not a little to the brilliant and hot weather of the past summer. Z. aurea is a Peruvian species, and bears flowers of the size and shape of a valotta, but of a rich golden-yellow colouring. F.C.C., R.H.S., December 5. Sir Trevor Lawrence, Bart., Burford Lodge, Dorking. (Gardener, Mr. W. Bain.)

SOPHRO-CATTLEYA LOTTE MULLER.

A very bright and pretty hybrid with flowers of good size and substance. The sepals and petals are rosy-purple, freely flushed with crimson-purple, while the lip is velvety-crimson with a fine gold-veined throat. The parents are Cattleya Petersi and Sophro-cattleya Nydia. F.C.C., R.H.S., December 5. Messrs. Charlesworth and Co., Haywards Heath.

TRICHOPILIA GOULDI.

A very interesting and pretty hybrid obtained by crossing T. suavis with T. fragrans. The large lip is whitish, freely spotted with pink, and with a yellow throat; the sepals and petals are white and pink. A.M., R.H.S., December 5. Messrs. Charlesworth and Co., Haywards Heath.

CARNATION BATH'S PREMIER.

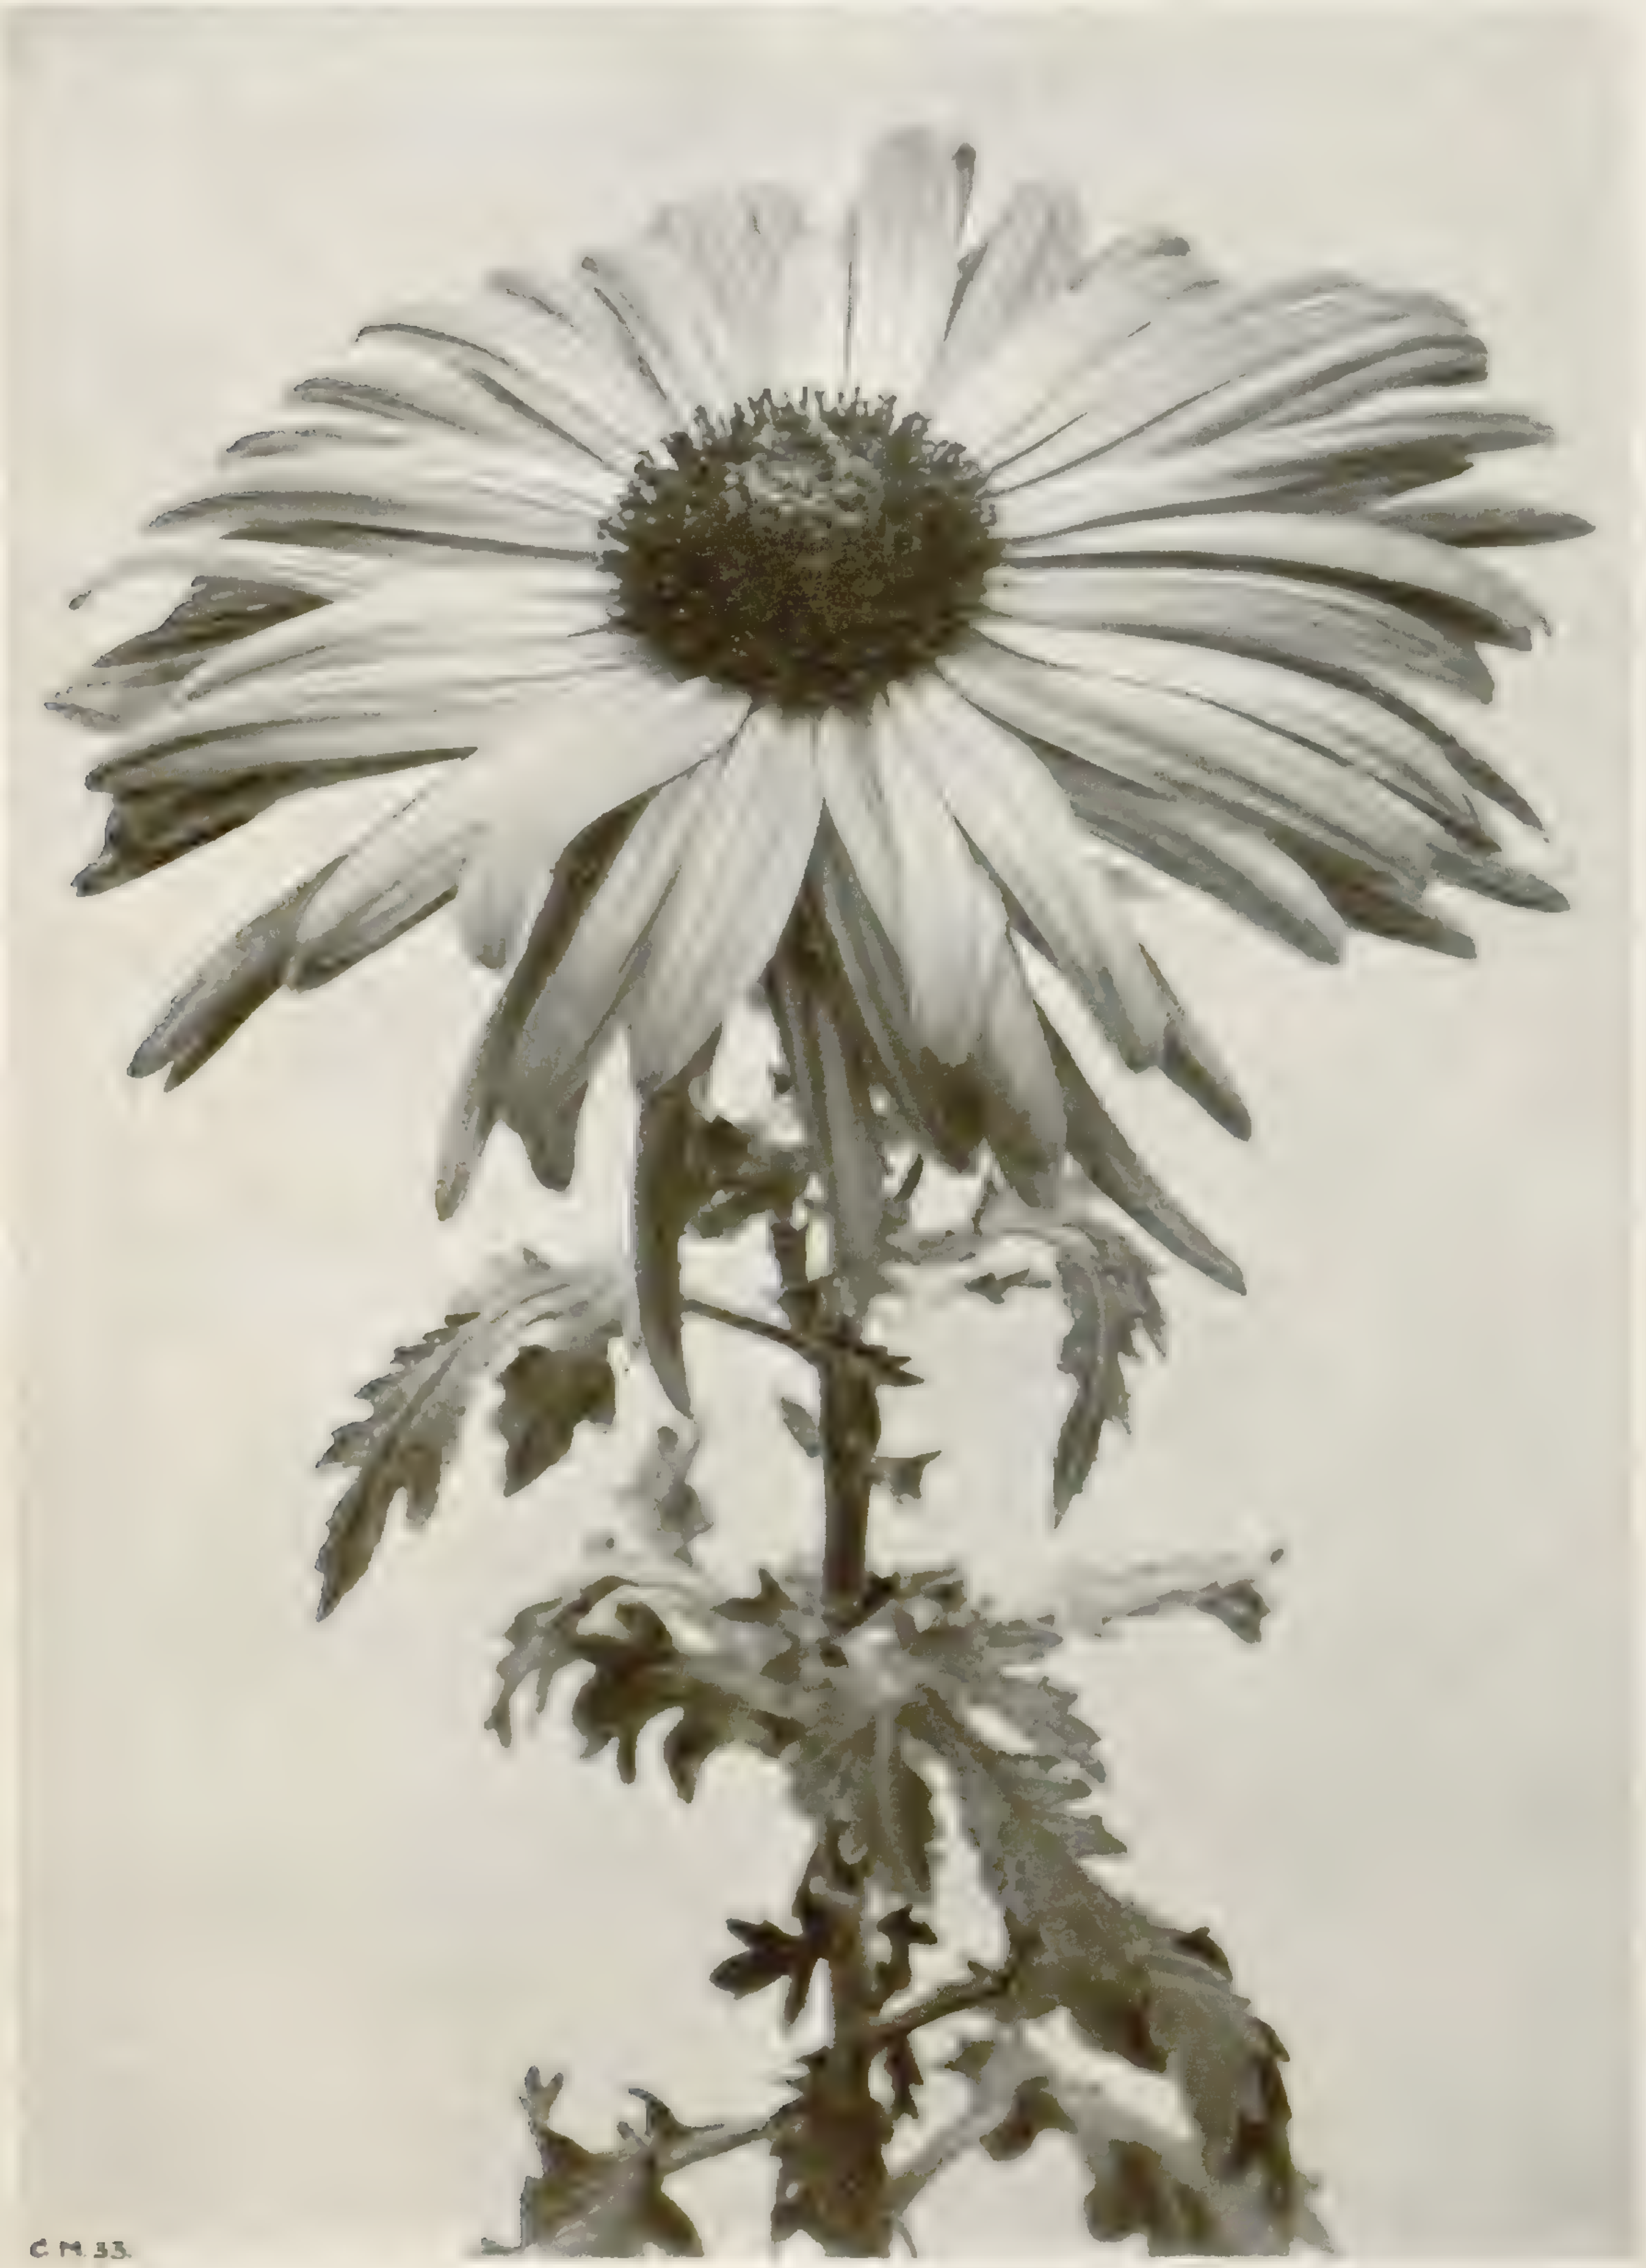
This excellent pale yellow perpetual carnation is descended from the famous "Lawson" variety, and is of similar habit and style of flowering. The blooms are of good size and substance. A.M., R.H.S., December 5. Messrs. R. H. Bath, Lim., Wisbech.

BEGONIA GLORY OF CINCINATTI.

Of the B. Gloire de Lorraine type, this newcomer is of American origin, and it surpasses the type form in producing larger, flatter flowers, and rounder leaves. There is little difference in colour, but possibly Glory of Cincinnati is a trifle brighter than Gloire de Lorraine. A.M., R.H.S., December 5. Mr. G. Lange, Hampton.

BEGONIA ALTRINCHAM PINK.

A very desirable new winter-flowering begonia of semi-tuberous habit. The plant is of excellent habit, and blooms with great freedom, producing pretty double flowers of a pleasing soft shade of carmine-rose. This addition is a very promising one, and was well shown. A.M., R.H.S., December 5. Messrs. Clibrans, Altrincham.



CHRYSANTHEMUM ISABEL GRAY.

A handsome single variety; crushed strawberry and buff are the colours associated in it. F.C.C., N.C.S., December 4; A.M., R.H.S., December 5. Mr. Phillip Ladds, Swanley Junction.

CHRYSANTHEMUMS.

Isabel Gray.—A fine single variety of large size and much grace; the colour is soft or pale crushed strawberry, overlaying or shaded with buff. F.C.C., N.C.S., December 4. Mr. Philip Ladds, Swanley Junction.

Bertie.—A very distinct single variety, best described as golden buff; very striking. Commendation, N.C.S., November 20. Mr. H. Lawrence, Shoreham.

Excelsior.—A good single variety, bright terra cotta, best as a disbudded flower. Commendation, N.C.S., November 20. Mr. H. Lawrence.

Brightness.—A striking flower of single form bright crimson, with a large yellow zone, petals rather pointed. Commendation, N.C.S., November 20. Messrs. G. Williams and Son, Cardiff.

Dr. C. L. B. Stares.—A decorative Japanese variety, with long quill-like florets, mauve-pink in colour. Should be popular for decorative work. Commendation N.C.S., November 20. Mr. P. Ladds, Swanley.

Miss Mabel Cooper.—A decorative single variety, rich deep rose with several rows of petals. Commendation N.C.S., November 20. Mr. P. Ladds.

Miss Margaret Gray.—A single variety, rich golden bronze, with perfect stems; a most popular colour. F.C.C., N.C.S., November 20. Mr. P. Ladds.

Miss Phyllis Bryant.—A splendid single, rich yellow, grand as a disbudded flower. F.C.C., N.C.S., November 20. Mr. P. Ladds.

Mrs. Whitehorne.—Another single variety, rich bronze, of excellent form and substance. Commendation, N.C.S., November 20. Mr. P. Ladds.

Mrs. Rees James.—A large single variety, blush, of a pleasing shade; best as a disbudded flower. Commendation N.C.S., November 20. The Millhill Vineries, Lim., Millhill.

Turvey Drop.—A good single variety, best described as a rich rosy-red, good in form. Commendation N.C.S., November 20. Mr. P. Ladds.

William Buckingham.—A charming single form, old gold in colour, the petals being somewhat freely arranged. Commendation, N.C.S., November 20. Mr. W. Buckingham.

Rhoda.—A decorative single variety, rich rosy red. Commendation N.C.S., November 20. Mr. G. Mileham, Leatherhead.

Rene Ellis.—A single variety of the Mary Richardson type, but richer in colour, which may be described as bright terra cotta. Commendation N.C.S., November 20. Mr. W. Higgs, Fetcham Park Gardens, Leatherhead.

Percy Arnold.—A single form, bright pink, good in the spray. Commendation N.C.S., November 20. Mr. W. Lingwood.

Millhill Beauty.—A large single form, pure white, of the Marsa type, and very fine as a disbudded flower. Commendation, N.C.S., November 20. Millhill Vineries, Lim.

Miss Elizabeth Stevenson.—A good single form, pale pink, light and graceful. Commendation, N.C.S., November 20. Mr. H. Redden.

Miss Elsie Davis. — A Japanese variety, rich rosy pink, large and solid, with fine reflexing florets. Commendation, N.C.S., November 20. Mr. G. Mileham, Leatherhead.

Miss F. M. Bird.—A fine exhibition single variety, blush-white, good litter in the spray or disbudded. Commendation, N.C.S., November 20. Mr. H. Redden.

Golden King.—A fine deep incurved variety, rich yellow in colour, and of capital substance. and build. F.C.C., N.C.S., November 20. Messrs. W. Wells and Co., Merstham.

F. Surrey.—A very handsome Japanese variety, rich crimson with broad strap-like florets; should make a fine exhibition flower. F.C.C., N.C.S., November 20. Mr. G. Mileham.

F. J. Mew.—A large exhibition Japanese variety, rich crimson with a gold reverse; a fine promising variety. F.C.C., N.C.S., November 20. Mr. Martin Silsbury, Shanklin, Isle of Wight.

Addie White.—A fine single variety of good form, reddish-bronze in colour, very distinct. Commendation, N.C.S., November 20. Messrs. W. Wells and Co., Merstham.

Polly Duncan.—A capital single form, perfect in outline, buff with a yellow shading. Commendation, N.C.S., November 20. Messrs. W. Wells and Co., Merstham.

W. A. Read.—A decorative Japanese variety of medium size, rich crimson, with good stems and foliage. F.C.C., N.C.S., November 20. Messrs. W. Wells and Co., Merstham.

Marjorie Lloyd.—Another charming single variety, rich golden apricot in colour, and of a perfect form. F.C.C., N.C.S., November 20. Messrs. W. Wells and Co., Merstham.

Browning.—A really good single, pure buff in colour with good substance, stems, and form. Commendation, N.C.S., November 20. Mr. Norman Davis, Framfield.

Market Buff.—A decorative single form of attractive appearance, and plenty of substance; rich buff in colour. Commendation, N.C.S., November 20. Mr. Norman Davis, Framfield.

Mrs. T. Brooke Edwards.—A Japanese decorative variety, of medium size, salmon-buff in colour, with narrow, refined florets. Commendation, N.C.S., November 20. Mr. Norman Davis.

Sir Walter Scott.—Another single variety, bright yellow, of fine form and with plenty of substance. F.C.C., N.C.S., November 20. Mr. Norman Davis.

Josephine.—A beautiful single variety, pure yellow, of the finest type; should make an ideal flower for exhibition. F.C.C., N.C.S., November 20. Messrs. W. Wells and Co.

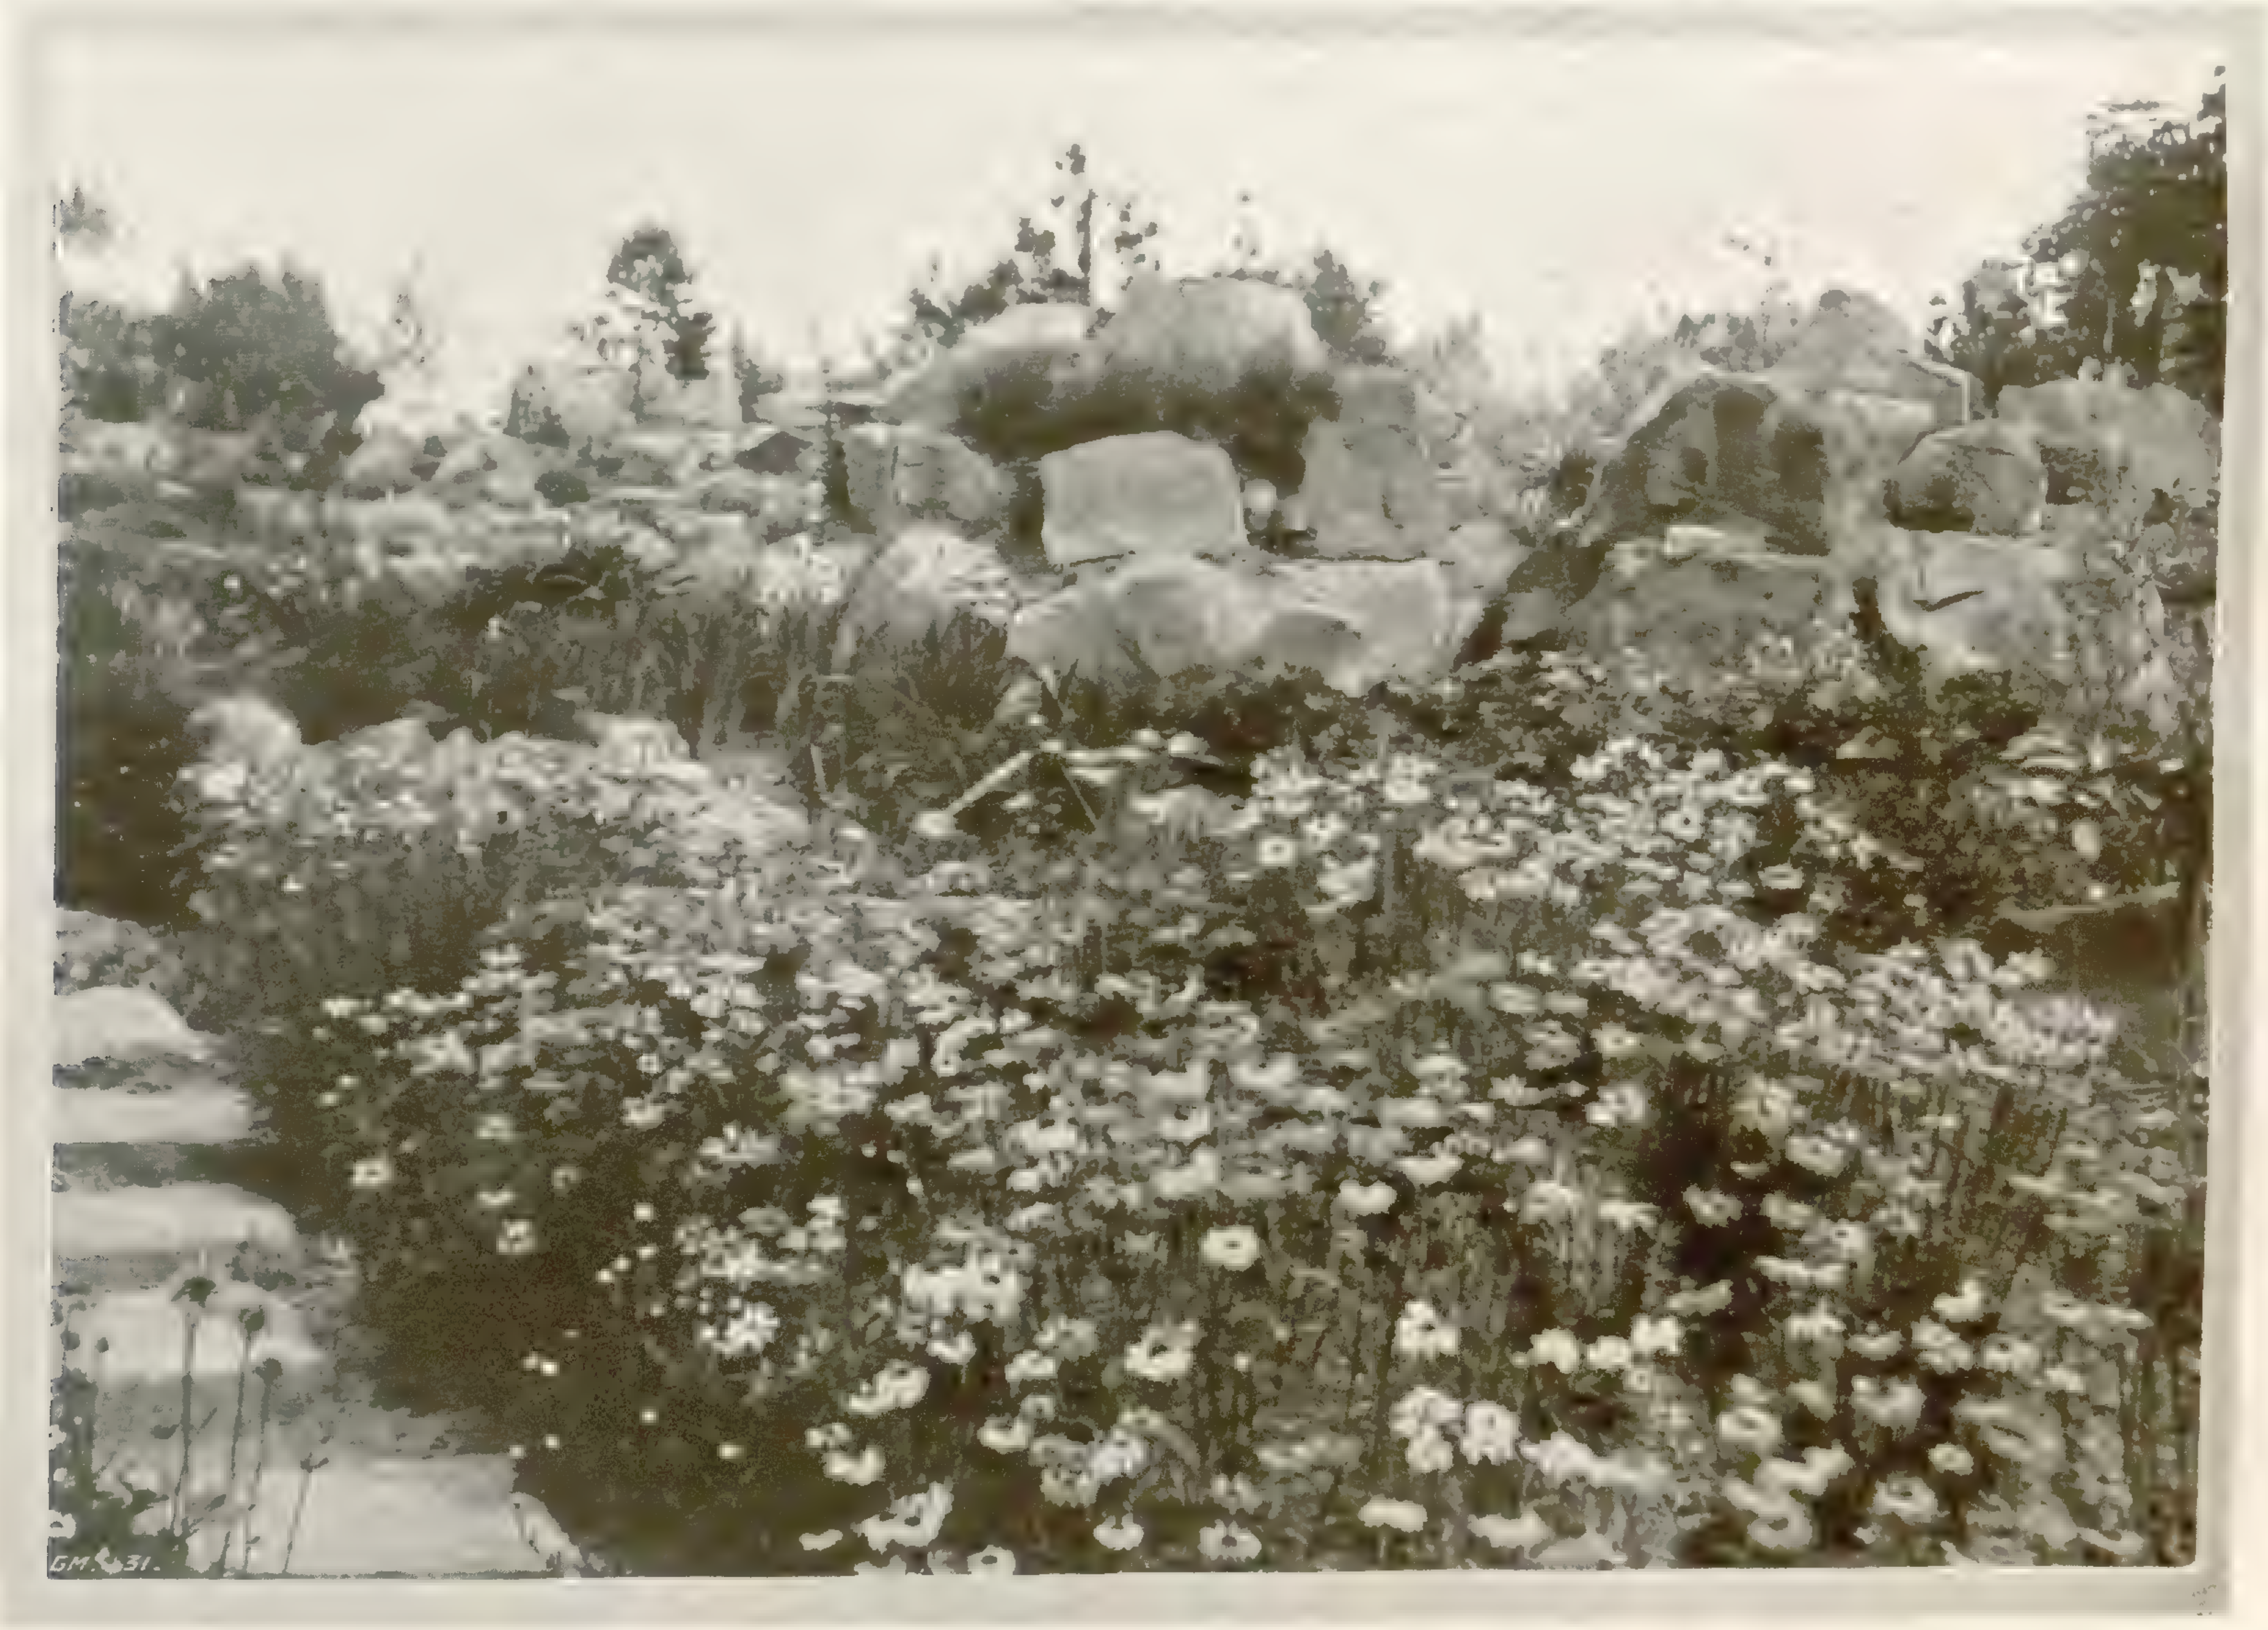
CHRYSANTHEMUMS.—For full instructions on the Culture of Early-flowering Chrysanthemums in beds or borders for garden or greenhouse decoration, read the Second Edition of Chrysanthemums for Garden and Greenhouse, by D. B. Crane, price 2s. 6d. net; or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

DAISIES IN GARDEN DECORATION.

In discussing the merits of daisies for garden decoration may I at once say that under this heading I purpose to include the leading subjects of the Daisy, or Composite order.

The valuable effects to be created by the use of daisy-like blossoms, both in the garden, and as cut flowers for the house, will be apparent to all who are interested in floriculture and decorative gardening. So many new varieties are being constantly introduced in the main families comprising the Compositæ, that one can choose from among them a series of plants that will yield a wealth of blossom the season through.

The colourings among them are invariably good, and the natural grace and dainty formation of the blossoms renders them fitting companions for a host of other and differing plants. With the idea of attaining a high standard of beauty, I would urge a comparative survey of the composites by all who have the care of gardens and pleasure grounds. They are essentially plants to group freely, bold sweeps of this, long drifts of that, and arranged, if possible, so that the eye is able to range from one plant to the other through the whole planting.



AN EFFECTIVE ARRANGEMENT OF PYRETHRUMS.
In the gardens of Holland House, Southcliff.

As a simple illustration of my meaning, may I refer readers to the accompanying view of a portion of the plantings of hybrid pyrethrums at Holland House, Southcliff. As will be noted, the pyrethrums are grown upon sloping ground, with causeways of stepping-stones between the groupings, thus showing the blossoms to the best advantage, and avoiding the flatness which might accrue from planting up a level site. Previous to the burst of pyrethrum blossom, these same slopes are aglow with the gold of daffodils, and later, after the pyrethrums are over, gladioli of the Childsi and Gandavensis sections take up the tale.

Other composites largely used include the gaillardias, which give a continuous display of colour from June until the frosts. Chrysanthemum maximum of the best varieties give practically the same period of duration, with ordinary care in soil attention and in keeping the plants from seeding. Mrs. Lowthian Bell furnishes our largest plantings, but a good range of seedlings give practically as pleasing results, with more diversity in height and habit. Of the latter, St. George, a handsome five-inch diameter flower, is being freely propagated. These forms of C. maximum are grand for blending with soft blue campanulas of the grandis and persicifolia types, with delphiniums of the Belladonna group, with the Caucasian scabious, or as foreground groupings to Auchusa italica Dropmore var.

Erigerons are valuable for their drifts of lavender-shaded blossoms, which are so profusely produced. E. speciosus is fine, but E. splendens and E. Quakeress are exceptionally attractive. Coreopsis, again, are of great utility, C. grandiflora and C. lanceolata being among the best known. Of the latter species the variety oculata, with its crimson blotch on the petal bases, is also of value.

Of Michaelmas daisies or starworts, and the host of late summer and autumn-flowering chrysanthemums I need not speak. It is sufficient to note the splendid effects which one can create by freely using them. The selection of good forms is of great service, and helps the planter immensely, the matter of colour and habit of growth being of the utmost importance to the success of both groups.

Further, one has only to note the value of helianthus and heleniums, heliopsis and vernonicas, doronicums and inulas, rudbeckias and anthemis, to mention just a few groups, to perceive that one is justified in claiming a fuller need of public appreciation of the composites. And note, too, the ease of arrangement of a few single chrysanthemums or pyrethrums in vases. The dainty form is there, only needing the simplest light arrangement, while the lasting properties of the majority of the composites is well known.

Tall flowers of the nature of digitalis, the campanulas, delphiniums, linarias, etc., are exquisite when rising from a grouping of composites, giving just that grace which is necessary. In the matter of propagation, the composites are especially easy subjects, responding readily to division, and also to reproduction from seeds and cuttings. There is no difficulty about either method, and the best young plants are those subjected to cool treatment. Young plants are far better than old-established clumps, and it is the rule here to lift and propagate the major portion of the stock each season. Chrysanthemums, Michaelmas daisies, Moon Daisies, etc., are all lifted, and carefully gone through. Good seedlings of note are perpetuated, and varieties which do not come up to the standard are discarded. It is only by weeding out (the process of constant selection) that one can bring a series of really first-rate subjects into existence. Furthermore, this annual lifting gives one the opportunity of keeping the soil in good working order, which is of the greatest importance in plant culture.

Lastly, I may add, in reference to young stock, that they are less likely to grow unwieldy and get out of hand, as is the case where perennials are left standing for long periods. Staking is simplified, and in many cases the young vigorous bushy growth is capable of maintaining a good habit, without the use of stakes and tying material surely a point worth noting

P. S. Hayward.

BEGONIA MRS. HEAL.

Although the popularity of Begonia Gloire de Lorraine as a market plant continues, probably not a few who own private gardens are beginning to tire of this useful plant, and are turning their attention to the cultivation of that winter-flowering race produced by crossing B. Socorana with the tuberous begonias. Mr. Allan, gardener to Lord Hillingdon, Uxbridge, and other growers, have from time to time shown varieties of this section in remarkably fine condition during the dull season of the year, and thereby demonstrated the value of the plants for decoration, as well as the fact that their culture offers no serious difficulties.

At Burnham Grove, Burnham, Bucks, Mr. W. Lawrence, gardener to E. Clifton Brown, Esq., grows these newer varieties extremely well, and has the variety Mrs. Heal, with bright carmine flowers, very fine indeed, and the specimen figured was 1ft. 9in. high; 2ft. 4in. wide, and carried 184 fully-expanded blooms at the time the photograph was taken. Mr. J. Heal, Messrs. J. Veitch and Sons' raiser and hybridist, confesses that the plants at Burnham Grove are the finest he has ever seen.

The following information concerning the production of such handsome plants is kindly given by Mr. Lawrence, as follows: "The plants were raised from cuttings struck in April, 1911, placed in a temperature of 60 to 65 deg., with a little bottom heat. When nicely rooted they were potted and kept in the same temperature until well established, when they were placed in a slightly lower temperature, and potted as soon as acclimatised. When the outside temperature became considerably higher the plants were placed in a close pit, and when well rooted in their new pots the batch was placed for two months (July and August), in a cool pit, and shaded through the middle of the day. In September, when the nights grew cool, a little artificial heat was given just sufficient to warm the pipes. When frosts were imminent, the begonias were moved to an intermediate house, and potted again, using a mixture of two-thirds peat and fibrous loam, and a third of sand. The good results achieved are, I think, due to the maintenance of as even a temperature as possible, and freedom from draughts. Great care must be exercised to avoid over-watering, and at all times the plants must be kept quite free from insect pests."

Anthurium splendidum.—In the Gardeners' Magazine of November 18 (page 863) there is a most interesting article on anthuriums by Mr. H. T. Martin. Your correspondent, I see, recommends among the foliage kinds, Anthurium splendidum, which I was under the impression had now dropped out of cultivation, and I would like to ask him if, to his knowledge, it is still grown? A native of South America, this species was introduced in 1882, and distributed as a new plant by the late Mr. William Bull, of Chelsea, in the following year. It is a very distinct species, the leaves being heart-shaped, and the surface regularly puckered. The evenly disposed veins have their course marked by a band of deep green, while the intervening spaces are pale green. This species was always difficult to cultivate, the leaves, unlike those of most anthuriums, being of a soft texture, and therefore very susceptible to injury. It used to succeed best in the close moisture of a propagating case. Owing to its exacting requirements A. splendidum never became a favourite, and I was under the impression it was now lost, hence my troubling you with this query.—W. T

CHRYSANTHEMUMS FOR MARKET.

The following is the text of the paper read by Mr. Ladds on this important subject at the conference held by the National Chrysanthemum Society on the 4th inst.:

For convenience, said Mr. Ladds, I have divided the paper into the following sections: Stock, Treatment of Stock, Taking the Cuttings, Potting, Stopping, Staking, Disbudding, Housing and Ventilation, Feeding, Insects and Mildew, Packing, Lifting, and Treatment of Lifted Chrysanthemums.

STOCK.

My first remarks therefore will be regarding the selection of stock. Great care should be exercised in the selection of plants which are to be saved for stock stools. Very often, wholesale growers collect a quantity of last year's stools indiscriminately, pack them tightly in a box, and take cuttings from them in due course.

Much the better plan is to select those from which you have cut the best blooms in the flowering season. They can be marked at the time of cutting the bloom, and all those that have shown inferior blooms, bad foliage, or any defects that a chrysanthemum is subject to, can be discarded. Among the defects of the chrysanthemum I would at present only enumerate one, viz., the leaf disease, which has made itself so prominent during the last two or three years. Plants with this defect should never on any account be used for stock stools.

My next point is regarding the treatment of stock. Having selected the best stools, and after having removed most of the soil, stand them upon a hard-based border and just cover them with some good fine loam. Great care should be taken in the watering, as an abundant supply will lead to failure, some varieties wanting scarcely any water until the cuttings have begun to show through the soil.

If the stools are left in the pots, a top-dressing would be advisable in place of the old top inch of soil, which is generally over strong from last autumn's manuring.

TAKING THE CUTTINGS.

It is difficult to fix any date as the best for taking cuttings, but, generally speaking, my experience has taught me that the later the variety the earlier the cuttings should be put in. To enumerate a few: M. Panckouke, Framfield Pink (and family), and the Thompsons, are all the better for early striking.

For striking a large quantity of cuttings, I have found the following methods to be cheapest and most successful: In an ordinary 12ft. greenhouse, with a centre path, pat the border down rather hard. Place a piece of 1in. by 3in. batten on edge at the back and front of the border, held in position by 9in. stumps driven into the ground on either side of the battens. In this bed place 2in. of good loam, containing no manure, but to which has been added about two shovelfulls of coarse sand to a barrow-load. Pat down firmly, and dibble the cuttings in, about 100 to a square foot.

The length of the cuttings should be about three inches. I might say here, that, when taking the cuttings, be sure to have an eye left on the old stool to break again later on, in case of a failure with the first batch. When dibbling them into the bed prepared as above they should be put in firmly, about one inch deep, and great care should be taken not to leave a hollow below the base of the cutting, as it is practically an impossibility to strike a chrysanthemum cutting that has any air under it. The cuttings should be taken off, made, and dibbled, within, say, two hours, so that no sign of flagging is visible. Cuttings, while striking, do not require much water, only just sufficient to keep the soil moist, with several sprinklings to prevent the foliage from flagging much, as the less they flag the sooner they strike. Tissue paper or newspaper can be used for shading if it is found necessary.

POTTING.

And now comes the important work of potting, more important, perhaps, in late varieties than in early ones. If the potting is done as soon as the cuttings have roots about 1in. long, they can easily be taken from the beds, and hardly any roots be broken in the process. Thus they only receive the slightest check. Regarding the size of the pots, a great deal depends on how the plants are to be treated later on. With some varieties, it is as well to pot into 3in. (60's), then forward into 48's, and finally into 24's or 16's. To these latter I will refer again. Other kinds can be potted directly into 48's, two, three, or four in a pot. In the first system, the plants should be potted into 48's as soon as the 60's are fairly well rooted.

At the first potting, frames are decidedly the best places to put the plants in, as the lights can be removed to give them the benefits of sun, air, and rain. If the plants are kept in an ordinary greenhouse they are apt to grow weak and soft, which is detrimental to success. While mentioning this matter, I should like to point out that it is a bad policy to neglect chrysanthemums as some growers do until they have time to attend to them. This means June, when the market bedding-plant season is over. Chrysanthemums, to be a financial success, must have every attention from the beginning.

Now as to 24's and 16's. For the final potting into these sizes, the best time generally advised is from May 7 onwards, every endeavour being made to get all finished by the end of June. I think it preferable to use 24's; as in the case of 16's, the pot is so large that, should the late autumn be wet and cold, the plants do not dry as much as necessary, and the soil is apt to become sour.

There are exceptions to this, of course, and one example of when 16's are preferable to 24's occurs to me, viz.: Tuxedo, with four plants in a pot.

Not the least important item in obtaining good results is the soil. I find that for the first potting a good loam is essential, with one part of decayed horse manure to fifteen parts of good loam. For the second and final potting; that is, from the 48's to 24's or 16's (it is really impossible to devote more time and money to potting when growing in a wholesale way for market), use a good loam, not too heavy, with the following additions: In November turn the loam, and in layers, add 8 per cent. of decayed horse manure, and in alternate layers add 1 per cent. of bone-meal. As regards the bone-meal, ground bone is the best. The several bone compounds now on the market may be as good, but personally I prefer ground bones, ground into a fine flour. When turning the soil again in May ready for using, 1 per cent. of soot, and ½ per cent. to 1 per cent. of Peruvian guano should be added. By preparing the soil in this way, very little artificial manure will be necessary during the midsummer months. The soot seems beneficial in several ways, chiefly by keeping away worms, the maggot fly and slugs.

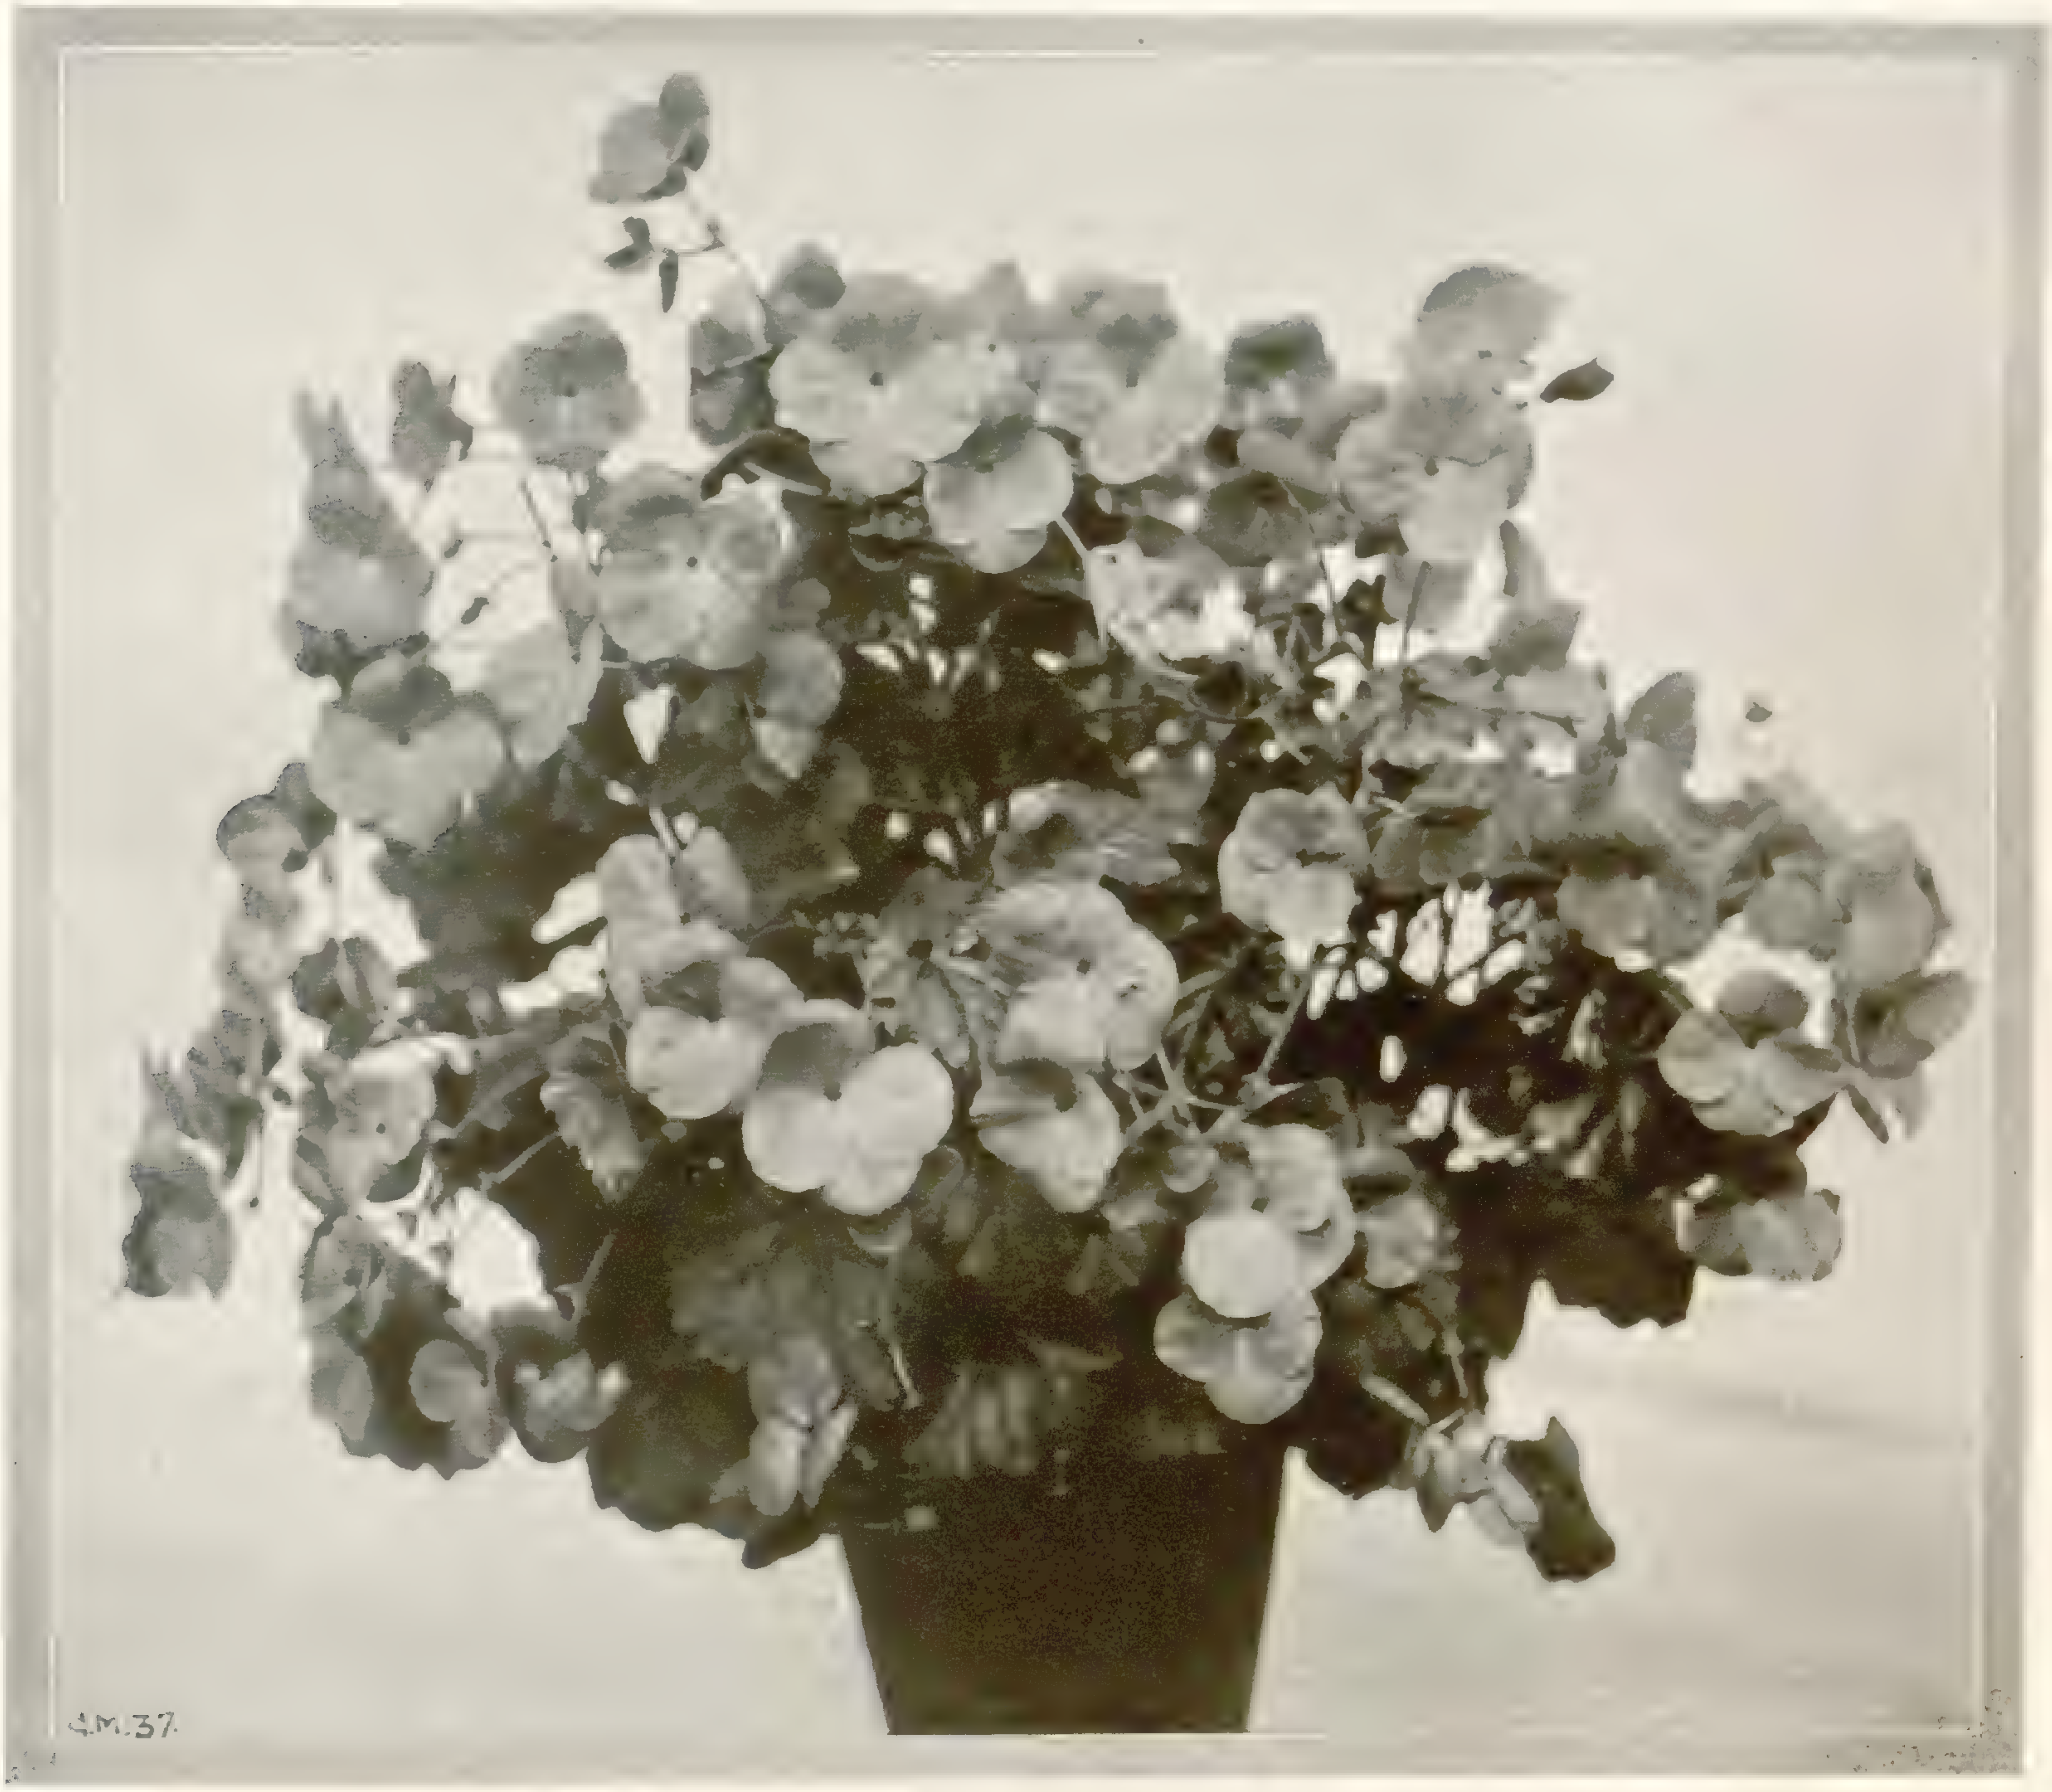
When this final potting is being done every care should be taken to have it done well, as there is nothing more important, and therefore every attention should be given to it. It should be seen that the pots are well crocked to ensure good drainage. A quantity of soil should be first placed in the bottom and rammed down. The ball of the plant should then be placed in the middle of the pot, more soil added, and rammed down regularly, so that the soil is of the same degree of firmness throughout. Sufficient space should be left to hold enough water to quite wet the whole of the soil at one watering.

Sometimes piecework is necessary in potting, but it is not advisable, as the work is so apt to be done in a careless, slipshod manner. No doubt it is the cheaper method at the time, but is it cheaper when the following autumn arrives? As an instance, suppose piecework potting costs 15s. per 1,000, and day work 20s. per 1,000. The difference is only 5s. per 1,000, or 6d. per 100, or ¼d. for four plants. Double this difference if you like, and it is an item that would be saved on watering alone, if nothing else. I strongly object to piecework potting, although I must admit that I have had potting done by piecework sometimes.

STOPPING.

I now come to stopping chrysanthemums but I am afraid that I cannot say much of a definite nature. It is impossible to stop a certain variety at any specified time, say, for instance, April 2, or May 2, as so much depends on the growth of the plant. It will be sufficient, perhaps, to give the various ways of stopping:

1. Stop once in late May, when in the flowering pot, and allow as many breaks to grow as will make a crop. The plant will probably finish six to eight growths; take next bud.



BEGONIA MRS. HEAL.

A fine specimen of this carmine-flowered winter-flowering begonia, grown by Mr. W. Lawrence, gardener to S. Clifton Brown, Esq., Burnham Grove, Burnham. It carried 184 expanded flowers, and was 1ft. 9in. high and 2ft. 9in. wide.

2. Stop once in the 48's, and once in the flowering pot, and take next bud.

3. Stop once in the 48's, and allow them to break naturally in the flowering pot. Dis-shoot them down to the number of shoots you think the plant capable of bearing, and take the next bud.

4. Stop in 48's, allow natural break in the flowering pot, then dis-shoot them to one break on a stem. Some varieties are better taken this way for disbudded blooms than stopping once and taking next bud.

These methods must be experimented with by the grower to find, first, which method, and also which date suits the variety.

To conclude these remarks on stopping I will mention a few varieties with method and date:

M. Panckouke.—Four in a 24, stop in 48's, in April; allow natural break and dis-shoot; take next bud. Wind the shoots round three sticks.

Framfield Pink.—Four in a 24, stop in 48's from March to May; take next bud.

Tuxedo.—Four in a 16, stop twice, April and early July, and take next bud; or, stop once, natural break, and allow all shoots to come for sprays.

Mrs. J. Thompson.—Two in a 24, stop twice, and take next bud.

W. J. Crossley.—One in a 24, stop in May in the flowering pot, and take next bud.

Valat.—Three in a 24, stop twice, early May and mid-June.

Cannell's Prolific.—Two in a 24, do not stop at all.

Mrs. D. Syme.—One in a 24, stop once only about the third week in May.

Allman's Yellow.—Three in a 24, stop twice, May and June.

Baldock's Crimson.—Two in a 24, stop once only, about third week in May.

I could continue mentioning varieties, but I do not think any more are necessary for the purposes of this paper. I do not suggest these rules and dates are the best: they are simply the ones I have made use of myself.

One more item is worth mentioning, viz., by stopping a large batch of one variety on one day, the blooms will probably have to be cut for market in one week; but by dividing the batch into three parts, and stopping on three different days with a range of a fortnight, the crop may extend to three weeks instead of one.

STAKING AND DISBUDDING.

This should be done early to prevent the wind blowing the shoots off the plants. Always remember that every shoot is worth money, and that it belongs to you, and not to the wind.

There are three methods of staking, as follows: (1) To string each shoot separately. Each shoot should be done quite independently, so that when cutting a bloom it can be removed without allowing the other blooms to fall over the pot. (2) One stick, with a band of raffia round the shoot, and fastened to the stick. (3) With three sticks. These should be placed close to the rim of the pot and raffia strung round the outside of them to form a similar arrangement to the patent carnation support.

The tops of the sticks should be tied to wires which have been stretched from end to end of the setting-out ground. This prevents the wind blowing the plants over.

Disbudding should be done as soon as the buds are large enough to handle. In some instances it is advisable to leave the top shoot next to the bud for two days longer. Should the bud not swell there is still a shoot left to grow on. As soon as the bud shows signs of swelling this top shoot can be removed. This refers to buds other than terminal buds.

HOUSING AND VENTILATING.

The best houses for chrysanthemums are those which have side ventilation and a good heating apparatus. Not because either or both of these are always necessary, but because a little of both is sometimes of great advantage. As chrysanthemums usually have to follow cucumbers and tomatoes in the houses, a general clear up should be given, not forgetting the glass inside and out, before the chrysanthemums are moved in.

Avoid placing the plants too thickly, or they will draw and grow weak; on the other hand, do not place them too far apart, or they will not pay for the room. Ventilation is a very important item, and should not be neglected. Plenty of ventilation is very necessary. An old grower's motto is "That fresh air is as good as a feed." Always bear this in mind. A little heat is generally necessary to prevent the flowers from damping, and also to allow them to develop properly. Always keep the atmosphere fresh and on the move by allowing a little ventilation. It is dryness as a rule that is required, and not a high temperature.

FEEDING.

Very little feed is necessary during the midsummer months if the potting soil is good. In fact, it can almost be made a rule not to feed until the disbudding is finished. Then feed a little at a time and often, up to within fourteen days from cutting the blooms. If the plants require a slight feed before the bud is formed, a weak solution of Peruvian guano can be applied by means of the water can, or preferably, add a little soot water with the guano.

When top-dressing with artificials, care must be taken not to burn the roots. The easiest way to ensure safety is to mix the manure with about twice the quantity of fine soil.

There are several kinds of chrysanthemum manures, all of which are good when once the grower has learnt the best way and times to apply them. Personally, I use a good deal of Peruvian guano, also Bull's food for plants. I have a great deal of faith in this last.

INSECTS AND MILDEW.

Chrysanthemums are attacked by many insect pests, these causing a great deal of trouble and becoming an expensive item. Prevention is much better than cure, and much cheaper. The chief pests (I do not know their titles from the insect peerage) are Greenfly, Blackfly, and Maggot. A weak solution of tobacco water sprayed on the plants at frequent intervals during the summer will be found a very good preventive, and will also eradicate any fly that is on the plants at the time of spraying. In place of tobacco water, a weak solution of nicotine will be found very effective.

The cheapest method of making tobacco water is to buy cheap tobacco paper or cloth, or, if possible, the rope that is taken from the bales of imported tobacco. Soak it in water, and dilute according to the strength thought necessary. This, I may mention, is a certain preventive for maggot.

When the plants are indoors, and the buds are beginning to burst, spraying is out of the question, and fumigating with a safe article must be resorted to. Nicotine compound, cones, and tobacco shreds can be used safely if used carefully. There are also other good articles on the market.

Another great trouble with chrysanthemums is mildew. Sulphur is a good preventive, especially green sulphur applied with a bellows or similar distributing contrivance. Liver of sulphur is also very good. Take a piece about as large as a cob nut and dissolve it in one gallon of water. Spray the leaves all over, taking care to wet the underneath part of the leaf as well as the top.

Regarding other diseases, a great deal might be written about prevention and cure, but I find that if a variety has a tendency to be diseased, it is as well to discard it instead of wasting time and money trying to cure it. There is also the possibility of infecting all the other varieties in the proximity in the meantime. In these times, market growers have not much time to spend on growing troublesome varieties, especially when there are many good varieties to devote one's time to.

CUTTING AND PACKING.

This is the most pleasant task in chrysanthemum culture, but, at the same time, it is one that requires skill. First of all, grading is absolutely necessary, whether the blooms are to be packed loose in a box, or to be bunched twelve in a bunch. The blooms in a box should be of uniform size. In packing, the chief thing to bear in mind is that the blooms should be as good when unpacked as before. Don't hurry over it. The same argument applies here as in the potting. It must be carefully done. Why spend nine or ten months in growing a good bloom, and then take 50 per cent. off its value in two minutes by careless packing?

Each bloom should stand in water, up to its neck if possible, at least two hours before packing. It will then look fresh, and when unpacked either in the market or at its destination, it will look the same. Cut as long a stem as possible, and never take off any green leaves.

LIFTED CHRYSANTHEMUMS.

I will now give you a slight idea of how our lifted chrysanthemums are treated. The cuttings are struck in February and March, and I usually put 200 in an egg case 4in. deep. When rooted, they are put in a cold house or frame. The stopping takes place when they are 6in. high, and in April they are put outside, having canvas handy to cover them up if the weather is frosty. The ground is prepared for planting, marking both ways so that the rows are 21in. apart one way and 18in. the other.

Planting takes place on the first suitable showery day in May, in just the same manner that the market gardener plants his cabbages. Weeding the fields is necessary during the summer. The plants should be stopped about the first week in July, or when they have made sufficient growth.

Lifting must be done before the frost arrives. We generally start about October 1, reckoning to finish by October 18. This is, of course, the most important detail of the crop. Some people say that it is essential to lift a large ball of soil with each plant. Well, it may be essential, but not possible when lifting ten acres or so. Dig the plants up from the field. Place as many as possible, without breaking any, in an egg case, tie round with a string, load eight cases on a horse trolley, and cart them to the greenhouse. Plunge the plants at once. Start by digging a spit across the house, then with the fork rake part of the fresh-turned ground towards you, so as to leave a straight walled trench. Place the plants firmly in this trench, incidentally sizing them so as to have the short plants at the back and tall in the front, or vice versa. Having done this dig another spit across the house, throwing the soil on to the roots of the plants. Tread down both sides of the plants if possible and continue.

Water should be applied as soon as convenient, thoroughly wetting the roots, and the plants as well. Most probably the plants will flag if the sun shines, but a sprinkling through a rose can will assist them to pull round. Leave full ventilation on at night. During the day shut the houses up and sprinkle lightly, should the flagging continue. As soon as the plants have made fresh roots, give them as much ventilation as necessary.

A few remarks will not be out of place on the points which go to constitute a market chrysanthemum. For a pattern let us take Framfield Pink. This is undoubtedly the finest chrysanthemum from the market growers' point of view. The only exceptions that can be taken to it are, that in some districts, being a late variety, it will not flower; also it is not a safe lifter.

Other than these faults, it is an ideal chrysanthemum. It has good foliage, and good stems, which are stiff enough to hold its flowers erect, and yet not so hard as to prevent the blooms from drawing water. The neck, between the top leaf and the flower, is not unsightly through being too long, nor is it too short so that the leaves are intermingled with the florets of the bloom. The petals or florets are of good form and substance. They are stiff or springy enough to maintain their proper position in the flower, even though the side of the flower may have become flattened after a long journey, by road or rail, by reason of close packing in a box. Again, it seldom shatters, even if carelessly handled, and will stand a great deal of rough usage, such as being carried about by hawkers loose in their arms. It is good alike for sprays and for disbudding. The sprays are real sprays, not a conglomeration of small blooms compressed together on the extreme end of a stalk. The habit is good, and it can be described as a free-flowering "'mum," allowing for the exceptions.

So much for Framfield Pink. Now, if a grower wishes to assure himself that a new variety, or a variety that he has not already grown, is of any use to him commercially, let him compare that variety with Framfield Pink on the several points that I have enumerated. If it passes the examination and is equal to, better than, or even nearly as good as Framfield Pink, that grower can congratulate himself on having found a good thing.

There is one little detail that I have not mentioned up to the present, and that is colour. This is a consideration in a market chrysanthemum, and I do not feel capable of laying down any hard and fast rule regarding colour. The foremost thing to bear in mind is that it is always best to grow those shades of colour that are most fashionable.

Mr. Ladds pointed out that his chrysanthemums being set out in summer near a railway embankment, they were very often well fumigated by the smoke from the locomotives passing, and he thoroughly believed that the absence of rust among his plants was due to this factor. He said he had noticed that plants under similar conditions in other places, and also plants in or close to towns, were practically always free from rust. He suggested that chemists might take this matter into consideration, and possibly find a substitute for engine smoke wherewith to combat rust.

Anemone Flowered Chrysanthemums.—The engraving of Godfrey's Perfection on p. 873 of the Gardeners' Magazine reminds one how seldom we see this type of chrysanthemum now at shows, much less in private gardens. A few years since it was thought necessary to cultivate at lease a dozen large anemone-flowered varieties besides as many anemone pompons. How fashion changes! At the recent Southampton Chrysanthemum Show a class was provided for decorative flowers in vases, one competitor staged about a dozen fully-developed blooms, each of Madame Herewege and Delaware, the latter creamy white; these along with a similar number of the incurved Romance, made a bold and effective display, and fully proved the value of these sections for decoration.—E.M.

Berried Plants under Glass.—For the embellishment of the greenhouse, and for various decorative purposes indoors, many berried plants are extremely serviceable. The choice is not limited to tender kinds, for some of our smaller-growing hardy shrubs are also useful. Of tender plants, one of the oldest and most popular is Solanum capsicastrum, which has long been extensively grown for market, and is equally appreciated in private establishments. The many quaint forms of capsicum, also form a very attractive feature in the greenhouse during the autumn months. That pleasing little shrub Ardisia crenulata will also at this season be laden with its bright red, sealing-wax like berries, which remain fresh and bright for a considerable time. The white-fruited variety is much less ornamental than the type. The drooping racemes of Rivina humilis, whose berries are bright red when ripe, are disposed in a very graceful manner. This Rivina needs a little more heat than the different subjects previously alluded to. Of hardy shrubs, which are much used for the same purpose, are the dwarfer aucubas, skimmias, and pernettyas, the berries of this last varying in colour from white to deep purple. One great advantage of the hardy shrubs is they can be used in cold and draughty spots, where the others would quickly suffer.—W.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

PLEIONES.—This genus is included botanically under the cœlogynes, but it presents so many differences from a garden point of view, that it seems preferable to keep it separate. Pleiones are distinguished from cœlogynes by the pseudo-bulbs, which are of annual duration only. The leaves are deciduous, falling after the growths have reached maturity. The flowers are produced with the new growths, immediately after the resting period, and as the different species flower at different seasons, though mostly the winter months, they are most acceptable and useful. They are in practically all cases tractable subjects, and can be accommodated in an ordinary intermediate house. Some of them commence their growth in October, and are usually in flower during the months of November and December. In all cases a general rule may be applied that the plants should be repotted immediately they have finished plants will be readily separated as the old when the plants have flowered.

POTTING.—I do not wish to imply that plants of these species require annual repotting, for if there is plenty of rooting space, and the potting compost is in a good condition, the plants do not require to be disturbed. Carefully remove all dead and decaying matter about the base of the plants and top-dress. Where potting is desirable, carefully remove the plants from the pot, if the compost is reasonably dry the individual plants will be readily separated as the old compost is removed; before repotting examine the base of last year's pseudo-bulb, to see that no scale or other insect pests are lurking there. We find the plants do best grown several together in baskets or pans, so that they may be suspended from the roof. These receptacles should be thoroughly clean and filled to about half their depth with broken crocks. The compost should consist of about two parts turfy loam to one part of peat and chopped sphagnum moss, with sufficient sand and finely broken lime rubble to render the compost porous. Plant the pseudo-bulbs at equal distances apart, and make the compost reasonably firm. A covering of finely chopped sphagnum moss on the surface adds to the good appearance of the plants when growing. Water with tepid rain water as soon as potting is completed, and be careful not to over-water; as soon as the pots are well filled with roots more liberal treatment may be given. A temperature of 55 degrees is ample during the winter months.

SPECIES.—The spring-flowering kinds, P. Hookeriana and P. Reichenbachiana are not plentiful, but they are most interesting plants, rarely seen outside botanical collections. Their cultural requirements are practically the same as that recommended above for P. maculata, P. lagenairia, and P. præcox, but being later in starting they need a little more attention in autumn when completing their growth.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CHRISTMAS DECORATIONS.—At this season of the year, when the country establishments are preparing for the reception of the usual Christmastide visitors, the gardener finds his time fully employed in making the place as bright and attractive as possible. The conservatory calls for special attention, particularly if it be attached to the mansion. This should be thoroughly overhauled and cleaned, and the plants rearranged. The colour effect of the arrangement must be well studied, avoiding all clashing of colours. Bold masses of colour are much more effective than dotting or mixing up the various plants employed. The material now at hand for decoration is plentiful, including as it does chrysanthemums, Lilium speciosum album, L. longiflorum, arums, poinsettias, Begonia Gloire de Lorraine, and the white variety Turnford Hall, cyclamen, salvias, and the different varieties of bulbs and forced plants. These, if judiciously arranged with the various forms of asparagus and ferns, will make a pleasing display. The temperature will need to be increased to suit some of the plants, and more especially so if the conservatory has to be used as a retiring room during balls and parties.

CHRYSANTHEMUMS.—No time should be lost in propagation, where large blooms are required. A start should be made with those varieties which flower on the second crown, and those which open late in the season. Select strong, healthy cuttings, and insert them singly in thumb pots, using a light compost consisting of equal quantities of loam, leaf-soil, and sand. They may be stood in a cool house, in a close frame, or plunged outside in a cold frame. The latter method is perhaps the best, but it requires careful attention in regard to ventilation, shading, and frost. The frames should be surrounded by a good layer of long manure, and an ample supply of covering material must be kept handy. Perhaps it is advisable, and certainly causes less anxiety, if the frames are matted up every night, whether it be frosty or not.

HIPPEASTRUMS.—If these are required to flower early a start should be made, selecting the strongest and best bulbs for the purpose. Remove a portion of the old soil without injuring the roots, and rectify the drainage. Fibrous loam and charcoal or lime-rubble forms a suitable compost for repotting. A mean temperature of 60 degrees is required to start the bulbs into growth. After the first watering in, little more water is required for a time, but frequent syringings should be applied to maintain a moist atmosphere.

POTTING MATERIAL.—Owing to the exceptional dry summer lately experienced, the cutting of turf has been delayed; but this work may be pushed forward now, and the loam stacked in a cool place. Should this be found poor or light, the addition of some short manure will greatly improve it. A quantity of last year's loam and leaf-soil should be brought into the potting shed, so that it may be handy when required.—A. GRUBB, Porters Park Gardens.

HARDY FRUITS.

PRUNING OLD ORCHARD TREES.—As the pressure of other work in the fruit garden becomes easier, the older standard or orchard trees will require attention. Many of these would be improved both in cropping capabilities and quality of fruit, if a judicious thinning of the branches could be carried out at intervals of a few years. One occasionally comes across instances of old trees that have been mutilated, branches four to six inches in diameter being sawn clean away with the idea of thinning; this is a very crude method, and one likely to upset the ideal aimed at, which should be the general health and well-being of the trees. The guiding principle should be to so thin out the wood, by removing interlacing branches, as to allow the sun and air to play on all parts, and also, as far as possible, to secure an even balance of branches throughout.

PRUNING YOUNG STANDARD APPLES.—It requires more care and knowledge to produce good standards than perhaps any other form of fruit tree. It will depend on the way these are pruned for the first few years after planting, as to whether the orchard will be a success in every sense or not. So much depends on the habit of growth and the way different varieties are treated. As an instance, Bramley's Seedling may, after the first four or five years, be allowed a free run, the side growths only being shortened; this variety should not have the centres kept open, as is the custom with trees of a more upright habit of growth, otherwise, when they become loaded with fruit, the whole of the branches will droop to the ground. On the other hand, Worcester Pearmain should have all leads shortened for a number of years, or it will take a backward course early in life. With other varieties much is gained by shortening the leaders every second year. Encourage the trees by every possible means to form good, well-balanced heads, expecting but little fruit for a few years, for, if one can afford to wait, the standard is no doubt the most prolific type of tree to grow in the long run.

BIRDS.—At the first signs of hard weather gooseberries, red currants, plum trees, etc., should be protected from the destructive sparrows, bullfinches, and other birds. Soot and lime freely dusted about the bushes when the twigs are quite damp will make the buds distasteful, and also have an excellent fertilising effect. There are also little contrivances known as "webbers," by means of which bush fruit may be webbed over with black cotton. Every means available should be used to keep the birds at bay. Sparrows migrate from the towns in thousands each year at harvest time, and, in spite of sparrow clubs, enormous damage is done to both buds and flowers by the cunning little adventurers.—J. WHITTLE, Cheveney Gardens.

THE KITCHEN GARDEN.

EARLY POTATOES.—The first important planting of early potatoes may now be taken in hand. Form hotbeds, perferably in pits, for their reception, and if sweetened manure and a good stock of leaves are on hand, it will facilitate matters for this crop. When making up these beds see that a good proportion of leaves is used, and the whole made firm by constant treading as the material is placed in position. Finish off the beds so that the crop will be tilted towards the sun and reasonably near the glass lights. Use open, sweet, rich soil to a depth of about ten inches. Plant the tubers from twelve to fifteen inches apart as soon as the fermentation of the bed has made the soil comfortably warm. Where proper pits or frames are not at command, or required for other purposes, a beginning may be made by filling a number of eight-inch pots with good soil and placing one strong tuber in each. These can be grown in a newly started fruit house with a temperature of from fifty to fifty-five degrees. The short topped kidney potatoes are very suitable for forcing; Sharp's Express and Duke of York are also favourites with many.

CUCUMBERS.—Make a sowing to produce plants to succeed those that are providing the winter supply, which, by March will have nearly exhausted themselves. If these early-raised plants are grown strongly in a light, close house, they may reasonably be expected to commence cropping by the end of March. Sow the seeds singly into thumb pots, and shift the young plants into larger ones as they make progress, until they have produced two or three rough leaves, when they may be planted out in beds of soil over hotbeds.

EARLY PEAS.—If accommodation is at hand, and a few early dishes of peas are appreciated, a sowing may be made in eight-inch pots, placing about nine seeds in each. The chief points to consider in their cultivation are: thorough drainage, a light, open, but rich soil, and keeping the plants near the roof glass in not too high a temperature, about fifty or fifty-five degrees being ample during their early growth. When the plants are firmly established give a plentiful supply of water, with intermittent applications of liquid manure.

RADISHES.—These are valuable additions to the salad, and may now be grown quite satisfactory over hotbeds, in wooden frames. A mild heat only is required for this crop, with as much air as can be given without cold cutting winds reaching the plants. If unduly forced the top growth becomes elongated and the roots comparatively worthless. Do not sow the seeds too thickly. "French Breakfast" forces well, has a very pleasing appearance, and is in every way a good radish.

GENERAL REMARKS.—The present is a suitable time to secure the stock of pea and bean sticks for next season. Bad weather is probable during the next month or two, and the staff can be profitably employed in open sheds when work is impossible outside, in getting them ready for use. Labels and brooms can also be made at these times. The rubbish, too, may be dealt with by turning it over, burning such parts that require it, and running portions through a sieve.—CHARLES FLACK, Cholmondely Castle Gardens.

EXHIBITIONS AND MEETINGS.

◆

National Sweet Pea Society.

The annual meeting of this vigorous society was held at the Hotel Windsor, Westminster, on Friday, December 8, at 2 p.m. Mr. G. W. Leak presided, and there were about a hundred members present, including a large number of people well known in sweet pea circles.

After disposing of the formal business, the Chairman moved the adoption of the report of the committee, as printed and placed in the hands of the members present. We give a few extracts:

REPORT OF THE COMMITTEE FOR THE YEAR 1911.

Quite early in the year difficulties arose in connection with the formation and election of the Floral Committee, due chiefly to the fact that there were no rules governing these matters, or for the guidance of the committee when elected. Eventually rules were adopted by a special general meeting, and under these rules the Floral Committee for the year was elected.

The society has sustained a great loss by the death of its trials superintendent, Mr. Charles Foster, who passed away in February last. Mr. Foster had conducted the society's trials of sweet peas since their inception, first at University College, Reading, and latterly at the Times Experimental Station, Sutton Green, Guildford. He occupied a high position in the world of horticulture, was one of the first authorities on sweet peas, and was held in the very highest respect by all who knew him. A number of the officers and committee of the society attended the funeral, and two large wreaths were sent as slight tokens of the esteem in which the members of the society held Mr. Foster.

During the winter of 1910, a great deal of the work of preparing for sweet pea trials of 1911 fell upon the shoulders of Mr. Harry Foster, owing to his father's ill-health. The work he thus begun fell wholly upon him on the death of his father, and the committee wishes to express its entire satisfaction with the manner in which Mr. Harry Foster carried out the trials in 1911, and to offer its congratulations to him upon his recent appointment as successor to his father at the Times Experimental Station. A record for the accession of new members has been established, no fewer than 303 having joined during the year. The membership shows a considerable increase, over 1,200 now standing on the books, notwithstanding losses from various causes amounting to 140. It may be necessary in the near future to safeguard the interests of the society by withholding the "Annual," and tickets of admission to the exhibition, until the annual subscription has been paid. Societies in affiliation now number 125, an increase of 16 for the year.

The society is in a sound financial position, having £150 on deposit, and a cash balance is again carried forward. The profit balance on the year's work is not so large as last year, and this is due chiefly to the increased expenditure in connection with the work of the Floral Committee, extra printing and postage incurred by several special meetings, and the grant of £25 to the International Horticultural Exhibition of 1912.

Brilliant weather was experienced during July 11 and 12, when the eleventh annual exhibition was held at the Royal Horticultural Hall, Vincent Square. Owing to the many festivities in connection with the Coronation of their Majesties King George V. and Queen Mary, attendance at the show was not so large as usual, and the receipts at the gate amounted to £41, as compared with £65 8s. 6d. in 1910. The exhibition for 1912 will be held at the Royal Horticultural Hall on Tuesday and Wednesday, July 9 and 10.

A large number of members visited the Times Experimental Station, Sutton Green, Guildford, on July 13, to inspect the society's trials. Our president, Lady Northcliffe, entertained the members with generous hospitality, presided at the luncheon, pointed out the many fine features of the historic old mansion of Sutton Place, and threw open once more the beautiful and famous gardens in which she takes such a personal interest. The following day a visit was paid to Messrs. R. H. Bath's floral farms at Wisbech, at the invitation of Mr. G. W. Leak, the chairman of committee, and a managing director of this great enterprise in Cambridgeshire. Here several miles of sweet peas, grown on wire netting, were inspected, as well as many other wonderful floral displays. Once again generous hospitality was provided.

The popularity of "The Annual" steadily increases, and the editors hope to provide as interesting an issue for the year 1912 as any that have preceded it. During 1912 the "List of Sweet Pea Names" will be issued as a separate booklet, and will be presented to new members, but charged 6d. post free to others.

The forthcoming schedule of prizes will be distinct from its predecessors in several ways. Classes for specified varieties have been entirely omitted, and novelties provided for in liberal fashion. The district classes are a quite new feature, as also are the classes for new seedlings and for flowers with double standards. General donations to the prize fund have been promised by many prominent trade and private growers, and it is hoped that many more friends of the society will come forward with financial help in this direction.

During the year 1912 the great horticultural event will be the International Horticultural Exhibition to be held in the grounds of the Royal Hospital, Chelsea, from May 22 to May 30 inclusive. Our society has contributed £25 towards the expenses, will present one gold and two silver medals, and has guaranteed a further £25 in the event of financial loss. There are several classes for sweet peas, and as several of our members have made arrangements for competing therein, it is hoped that they will secure the awards. Mr. N. N. Sherwood has promised a fine silver cup for sweet peas. Messrs. Walter P. Wright and Chas. H. Curtis are the society's representatives on the General Exhibition Committee, and other sweet pea celebrities who are either on the executive or general committee include Messrs. N. N. Sherwood, V.M.H., W. Cuthbertson, J. Green, R. H. Pearson, A. W. Sutton, V.M.H., G. Gordon, V.M.H., Robt. Sydenham, Horace J. Wright, J. S. Brunton, E. Molyneux, V.M.H., E. Laxton, F. W. Harvey, and E. F. Hawes.

The report concluded with thanks to the president and all who had contributed to the success of the society.

The financial statement, duly audited, showed a turnover of £932 15s. 4d. On the income side, the subscriptions amounted to £361 17s. 7d.; fees from affiliated societies, £66 3s.; advertisements in "Annual" and schedule, £44 5s.; takings at London show, £41; prizes presented, £112 17s.; and trials charges, £30 7s. 6d. On the expenditure side the chief items are: Printing and stationery, £213 4s.; trials expenses, £57 4s. 6d.; honorarium to secretary, £63; postage and carriage, £52 16s. 9d.; medals, £66 4s. 3d.; prizes, £99 0s. 6d.; placed on deposit, £50; contribution to International Horticultural Exhibition, £25. The final result is that the society has now £150 on deposit at its bankers, and, in addition, carries forward a balance of £98 7s. 10d.

The motion was seconded. Two amendments to the effect that members should not receive the "Annual" or tickets until subscriptions were paid, were defeated, as also was a motion to appoint a sub-committee to consider the desirability of reducing expenditure on printing and stationery. It was pointed out that these items were very little above the corresponding ones of 1910, and that matters were quite safe in the hands of the committee. The motion for the adoption of the report was then put, and carried unanimously.

Votes of thanks were accorded Lady Northcliffe, the retiring president; Mr. E. Sherwood, the treasurer; the committees, and to Mr. G. W. Leak, the retiring chairman, to whom a suitably engraved medal was presented by Mr. C. W. Breadmore, on behalf of the Society. Mr. Robert Sydenham was elected president, and Mr. Thomas Stevenson chairman for the ensuing year. Mr. Edward Sherwood was re-elected treasurer; Mr. R. Gluyas as auditor, and Mr. C. H. Curtis as hon. secretary, the latter being voted a handsome honorarium for his services during the year. The election of the General Committee, taken a little later, could not be declared until dinner-time, owing to the heavy voting, but the result was a magnificent vote of confidence in the committee, the only alterations being the return of Mr. G. W. Leak in place of Mr. Stevenson, elevated to the chair; and the addition of Mr. Vernon Hill, in the place rendered vacant by the death of Mr. Charles Foster. Mr. F. J. Harrison, of Ulverston, was added to the list of honorary corresponding members of committee.

The proposed alterations of rules were then taken, and we may say at once that the discussions on these matters were on a very much higher plane than those of the special meetings early in the year, to the very great advantage of business procedure. There were, of course, numerous amendments, and a number of these were not seconded. The General Committee's proposals were adopted until Rules 8 and 9 came up for consideration; these relate to the election and constitution of the Floral Committee. Rule 9: "The Floral Committee of the National Sweet Pea Society shall consist of nine members of the Society, irrespective of whether they be amateurs or traders," was taken before Rule 9. The committee's proposal to add words rendering anyone ineligible for a seat on the Floral Committee who had an interest in any variety on trial, was strongly condemned by Mr. George Gordon and defeated by a very large majority, notwithstanding the support of Mr. W. P. Wright and others; an amendment to the effect that members of the Floral Committee should retire when a variety they were interested in came under consideration was lost also, in view of the method of voting already established, which discounts the vote of any interested member. In the end, the old rule as quoted above was adopted by fifty votes to six.

Rule 8 came next, and it refers to the method of electing the Floral Committee; this hitherto has been in the hands of the General Committee, but the latter proposed that election should be by ballot of the members present at the annual general meeting. The Rev. J. Jacobs proposed a postal ballot from a list submitted by the General Committee, and Mr. Lumley wished to place at least two lady members on the Floral Committee, but at the last moment he somewhat ungallantly withdrew his proposal. The General Committee's proposal was adopted by forty-two to two votes, with the addition of the following words, as proposed by Mr. W. Cuthbertson, seconded by Mr. Sydenham, "One-third of the Floral Committee (those members receiving fewest votes) shall not be eligible for election the ensuing year." This addition was unanimously adopted.

Regarding the inspection of trials it was agreed that each set be visited at least once in the season. At this point Mr. F. J. Harrison, of Ulverston, called the committee over the coals respecting a Northern Trial; he felt that Hinckley, where it was proposed to hold this trial, was not sufficiently far north, and he said he had a good site in view, and at small cost, two hundred miles north of London. He believed this would be more in the interests of the northern members, whereas Hinckley, in the Midlands, would practically place all the good work of the society at the doors of the Southerners. Mr. Harrison spoke with some force and conviction. The Chairman pointed out, however, that the committee had been in communication with authorities in the Northern Counties, in Yorkshire, Cumberland, and Northumberland, but without success in this matter, and Hinckley was the only suitable place in view. It was agreed to hold over the final decision regarding the Northern Trial pending the consideration of a communication which Mr. Harrison promised to make to the committee. Rule 20, regarding the bracketing of "identical varieties," was deleted, and a new one added, i.e., "No award of any kind shall be made to a variety that, at the Trials, contains a rogue or rogues." These alterations have the effect of placing the three best sweet peas of each colour class, in alphabetical order, instead of in order of merit; and of bringing the annual general meeting into the month of October, instead of December, as heretofore.

The scrutineers, Messrs. A. Hallam, R. Pinches, E. F. Hawes, and W. Quick, had an unenviable task, and as they had not finished their task when the vote of thanks was cordialy passed to the chairman for his admirable services, they did not receive the formal thanks which we are sure everyone agreed they deserved.

And so ended one more busy, vigorous, pleasant, and historical meeting.

DINNER.

The new President, Mr. R. Sydenham, presided over about three dozen members, and with his usual generosity provided wine, and, subsequently coffee, cigars, and cigarettes also. The dinner was capitally served, and excellent good humour prevailed; indeed this function was a splendid foil to the sterner business of the annual meeting, which lasted from 2 p.m. to 6.30 p.m., and was excellent preparation to the conference that followed.

The loyal toasts were duly honoured, and the Chairman gave "Success to the National Sweet Pea Society," and in doing so foretold a prosperous year for the Society and for sweet peas and sweet pea lovers, and promised to do his very best to advance the interests of the Society, and so justify the honour that had been conferred upon him. Mr. F. J. Harrison responded in breezy fashion, making a capital speech and referring to the growing enthusiasm for sweet peas all over the country, and, of course, especially the Ulverston district. A vote of thanks to the President concluded this part of the day's programme.

CONFERENCE.

The Conference, commencing about twenty minutes past seven p.m., and presided over by Mr. G. W. Leak, was well attended, nearly seventy members being present. Mr. Leak welcomed the members to the third sweet pea conference, and expressed the belief that this would be as interesting as the previous ones. He then introduced Mr. F. J. Chittenden, Director of the Laboratory, R.H.S. Gardens, Wisley, and asked him to give his lecture, which we have now the pleasure of publishing.

DISEASES OF SWEET PEAS.

Growers of sweet peas are fortunate so far as diseases of their favourites are concerned. When we compare the numbers of pests which roses, chrysanthemums, carnations, and similarly widely cultivated plants have to contend with, and the large literature that has grown up around the subject of pests of these plants, sweet pea lovers may reckon themselves indeed fortunate, for it is easy to count the serious troubles to which sweet peas are prone on the fingers of one hand.

In the animal kingdom aphides and thrips are occasionally a trouble, but these may be kept in check by spraying with a nicotine wash or with quassia and soft soap, and so long as the operation, when necessary, is thoroughly and timely done, they need cause no anxiety. Besides these, if we except the ravages of mice and birds among unprotected seeds and seedlings, slugs and snails are the only menace, and methods of keeping these in check are so well known that they need not detain us.

So far as fungi are concerned, only two need concern us long—one attacks the leaf, the other the root.

Thanks to the kindness of your sub-committee, I was enabled to examine in 1910 a considerable number of specimens of diseased plants from your members, and these were supplemented by large numbers of others sent to the Wisley Laboratory from other sources.

Practically all of these plants were attacked by fungi, and it has become clear from experience in the laboratory and in examination of many collections of sweet peas in various parts of the country, that there are two troubles of outstanding importance due to fungi, viz., the disease called "Streak," and the "Mildew."

The mildew found in certain circumstances on sweet peas is apparently a very common one on a large number of plants, and seems to be identical with one which attacks the culinary pea. Only now and then does it appear to any serious extent upon sweet peas, and then usually when they are either overcrowded or have received a check possibly through drought, or some similar cause. The fungus in this case is, with the exception of some sucker-like organs which it sends into the leaf, entirely superficial, and can be kept in check with comparative ease; dusting with flowers of sulphur or spraying with potassium sulphide (liver of sulphur), using 1oz. to 3 gallons of water, at intervals, being an effective mode of dealing with the pest.

Far and away the greatest number of diseased plants sent to us have, however, been affected by the mysterious disease known as "streak." In its most typical form the symptoms of this disease are brown or dark brown streaks in parts of the stem, yellowing of the shoots near the ends of the growth, crippling of the flowers (those formed often being flimsy), the dropping of buds, brown spotting of the leaves, and finally collapse and death. Not all these symptoms are always present, sometimes even the brown steaking of the stem is absent.

The first specimens of plants attacked by this disease I had to examine had no root attached, and I searched in the leaf spots and brown stripes for fungus mycelium, for bacteria, or evidence of insect attack. All alike were absent. True, the cell contents were brown and coagulated; the protoplasm of the cells in the affected areas, which passed more or less deeply into the stems, was disorganised; but that is only what one might expect if the protoplasm had died. Even uncongenial weather conditions may bring about some such result in plant cells. Who has not seen black spots on orchid leaves?—often the direct outcome of careless, unintelligent use of the syringe. The protoplasm in these cells is wholly disorganised, and their contents assume a brown or very dark colour.

Now and then, on some of the spots or stripes, a fungus has developed on keeping, but never under such circumstances as to suggest that it had been the cause of the spotting or striping in the first place. Recently, Mr. Dyke, of St. Margaret's, has informed me that he has found a species of macrosporium develop from these brown spots on the foliage and the stripes on the stem, and that he considers it highly probable that this fungus has been the cause of the trouble. If he is right, then probably spraying will keep it in check, but many seem to have tried spraying and failed to ward off the disease. The last fact does not, however, negative Mr. Dyke's view, but we have some positive evidence which does not altogether fall in line with it. I hope, however, Mr. Dyke will follow up his investigation and try inoculation experiments and so on.

Later on, I had the opportunity of examining more complete plants, roots and all, and wherever the material was carefully lifted and packed we noticed very dark areas on the root. I had already come to the conclusion that the symptoms typical of the disease might be produced by something wrong at the roots; some of them were evidently the result of a check to the water supply, but others looked much as though some poisonous substance were circulating through the plant.

Careful microscopic examination of the brown patches—and one must insist on the need for care; hasty examination may fail to reveal anything—showed that they were attacked by a fungus which turned out to be Thielavia basicola. The same fungus was present in practically every case, sometimes abundantly fruiting, sometimes with only a few spores. When the disease was far advanced the brown areas involved large parts of the roots, and many of the latter would be found to be quite dead. Thus we had now a definite suggestion to work upon. The finding of the same fungus on practically every diseased plant showing approximately constant symptoms, does not constitute proof that it is the cause of the disease. We must show that if the living plant is infected with the fungus the same symptoms will be produced in it, and the fungus will fruit again so as to prove its identity. We therefore started some sweet peas in pots of sterilised soil, inoculating some of the pots with the fungus and leaving an equal number not inoculated. While they are developing we may leave them for a time.

A student of plant disease always finds it profitable to make himself acquainted with the history of the fungus which he suspects of causing disease, and an examination into the history of this one proved both interesting and profitable. We find it first referred to under the name of Torula basicola in the "Annals and Magazine of Natural History" in 1850, where the veteran mycologist, the Rev. M. J. Berkeley, whom we might almost call the father of the study of plant diseases, describes it as having been found on the roots of nemophila and the culinary pea. The plants on which he found it were dead, but he evidently regarded it as a suspicious organism, for he says: "It is either destructive of the plant on which it grows, or is developed on it in consequence of previous disease."

We need not now follow the references to it in literature in detail, but we may note that it has subsequently turned up in many different countries (it is well known in Germany, Italy, France, and the United States), and on a large number of plants belonging to many different families. When we remember that violets, begonias, cyclamen, lupines, French beans, culinary peas, tobacco and nemophila, members of six different families not at all nearly related to one another, have had the fungus on their roots, that again is enough to cast suspicion upon the fungus as the actual cause of the trouble, for most parasitic fungi are restricted either to one species of host or to a small group of allied host plants. Cases are, however, known where the same fungus is able to live on a large number of different hosts.

During the sixty years that have elapsed since its first discovery, the fungus has received several names, but it was found by one investigator that it produced several forms of fruit, and the name by which we now know it is Thielavia basicola, the name given to the highest form of fruit produced. Many of those who have examined the fungus from time to time have had serious doubts as to whether the disease shown by the plants on which it was found was actually occasioned by the fungus or not, but they have in most cases come to the conclusion that they were actually dealing with the parasite that caused the disease. Thus Thaxter attributes a serious disease of violet in America to it; Aderhold a like attack on French beans; Massee and others a disease of the culinary peas; and many vegetable pathologists in Italy and the United States attribute the most serious disease of tobacco to the same cause.

To return—the plants grew and flourished, alike those in the soil I had inoculated and those in the soil that was not inoculated. The experiment failed to demonstrate any connection with the fungus at all. I repeated it, using this time soils containing acid manures like superphosphate, and others well limed, but again the plants all flourished. My experience would thus lead me to suppose the fungus could not produce the disease, although it was always found with it; but I reviewed what I knew of the conditions under which it occurred. Unfortunately, the replies sent to the questions sent out on the schedules by your sub-committee did not help to elucidate the matter. The disease had occurred on all sorts of soils; it was associated with a number of different varieties; some varieties seemed more susceptible than others in one garden, but the same varieties were apparently immune in another; the seeds of the attacked plants had come from a variety of sources, and the seeds from one particular source did not always, or usually produce diseased plants.

I had never had more than a stray diseased plant in my own garden, although I had grown sweet peas in Chelmsford on a stiff clay soil, in Broomfield on an ideal loam overlying gravel, and in Cobham on one of the lightest sands it could ever distress the heart of a gardener to deal with, and among them were, of course, some of the supposed delicate varieties. But then I did not grow for exhibition; I was content with plenty of sweet-scented flowers with beautiful colours and lasting substance. I did not hanker after spikes with eight flowers or even five, nor standards three inches across. Could it be that the desire for "exhibition" blooms had led to over-manuring, to over-stimulation, and resulting after weakness.

The fact that the disease was apparently a new one, having attacked sweet peas only since the cultivation had spread so widely—and possibly due to the Sweet Pea Society—seemed to lend colour to this view. But I found that Aderhold had had in Germany similar difficulty in causing the fungus to grow on French beans, although they had been carried off wholesale by a disease associated with the fungus. He succeeded with some inoculations, however, after repeated trials. So I took heart of grace, and tried again.

I had noticed that very often, in fact, nearly always in 1910, less frequently in 1911, eelworms were round about the roots, and places which had apparently been "nibbled" by them were frequent on the roots. It seemed possible that the fungus might attack the root only after it had received some injury, and this time the plants, both in soil inoculated and that not inoculated, were badly treated by over-watering. Neither lots flourished as they should have done, but those in the soil not inoculated struggled on and flowered themselves to death. Of those in the inoculated soil, however, 75 per cent. died, showing the yellowing of the foliage, etc., typical of the disease, and on examination the fungus Thielavia basicola was found upon their roots, while those of the healthy plants were free from it. It seems, therefore, to be clear that under certain circumstances, and especially after injury or check to the root, the fungus Thielavia basicola may become a parasite, and my experience coincides exactly with that of other observers.

We thus see that we have other facts of great importance in the chain of evidence—we can inoculate plants of low vitality with the fungus, and it will produce in its host the symptoms associated with the "streak" disease, and will produce its spores upon the diseased tissues. These spores are thick-walled and resistant, and will live for a considerable time in the soil ready, no doubt, to infect fresh plants when the conditions suitable for their growth recur.

Now, from what has been said it seems evident that there are two things to which attention may be paid in attempting to deal with the disease.

The first and most certain would be to kill the spores of the fungus which are present in the soil. This can readily be done in soil in small bulk by steaming it or otherwise raising its temperature to about 180 deg Fahr. or over. The process outdoors is, however, much more difficult, and practically the only thing that could be done would be to thoroughly soak the material which it is desired to grow the plants in about three weeks before the seeds are sown or the plants transplanted, with a solution of formalin; carbolic acid, or lysol, might possibly be similarly effective. The application of steam for purposes of sterilisation, though not impossible, would be difficult outside. It does not seem practicable to use any fungicide in the soil during the growth of the crops, and certainly spraying the tops of the plants would be entirely useless, so far as this fungus is concerned.

It would appear, though one does not like to speak too positively, that a most important means of dealing with the fungus lies in maintaining the vigour of the plant at its highest pitch. That does not by any means indicate that it is desirable to grow the plants as large and sappy as possible. Indeed, it may well be that too heavy manuring will lead to trouble by making the plants less resistant than they would otherwise be to fungus diseases. It would seem very desirable, too, to see that the drainage is thoroughly efficient always, for nothing so quickly lowers the vitality of earth-dwelling plants as stagnant water about their roots. Another thing to guard against, and I fear a very common practice, is to put thick layers of dung at intervals, with earth between, in a kind of multilaminate sandwich. The manure ought, when used, to be mixed very thoroughly throughout the soil, and not to be put in layers, for its decomposition may lead to the formation of substances that are poisonous to crops and damage to any roots that come in contact with the substances produced.

DISCUSSION.

Mr. Chittenden was listened to with great interest and close attention, and a fairly brisk discussion followed his remarks, though this took the form of short references to success or failure with sweet peas. The most curious fact was that under apparently similar conditions, one member had great success while another had complete failure. Mr. H. A. Perkins' failures even after sterilisation could not be explained on any grounds. Mr. T. Stevenson stated that he had no disease in the sweet peas he had grown for exhibition, whereas Mr. Voss said he lost all the plants he grew well. Mr. Sydenham expressed a firm belief in new sites for sweet peas, and immediately Mr. H. J. Wright related how a certain Surrey enthusiast had been very successful, and had had no disease after seventeen years' continuous cultivation of sweet peas on the same site, and on sandy soil. Mr. Usher also said he could grow sweet peas very well on the same site year after year, but when he broke up new land for them the plants succumbed wholesale from streak and other diseases. Mr. Weeks, of Bromley, and Mr. Leech, of Dulwich, both spoke of the evils of watering, especially watering with tap water in the evenings. Mr. Malcolm expressed a strong belief in drainage and soil aeration; Mr. Weston thought firm soil one of the secrets of success, and Mr. W. Cuthbertson's suggestion that lime was often needed to help the nodule-forming bacteria met with very general approval. Mr. Vernon Hill, Mr. A. Bunyard, Mr. F. J. Harrison, Mr. Aley, Mr. Davidson, the chairman, and others all joined in the discussion.

Mr. Chittenden, in replying, said that the use of sterilised soil for the seed bed was a most valuable aid to strong plants and freedom from disease; he advocated the use of lime on clay soils and Chalk on sandy soils. He did not know how long the dormant spores of streak disease might lay dormant, but he pointed out that as long as the plants were healthy and unchecked the disease would not attack them. The aim therefore should be to secure steady, sturdy growth, and avoid checks to root or stem.

Mr. Chittenden was cordially thanked for his paper.

Two other papers were read, one on "Packing Sweet Peas for Exhibition," by Mr. T. Stevenson, and the other on "Packing Sweet Peas for Market," by Mr. Thomas Page, and the text of these we propose to give in our next issue.

A vote of thanks to the readers of papers was heartily accorded on the motion of Mr. George Gordon, V.M.H., and Mr. Leech, while a similar hearty vote to the chairman was given on the motion of Mr. W. Weeks and Mr. Alsen. This brought a busy day to a close, as not a few of the officers and committee had been on duty since twelve noon, and it was now about half-past ten p.m. Who says the enthusiasm in sweet peas is declining?

An edition of "SWEET PEAS AND THEIR CULTIVATION," by C. H. Curtis, has just been issued for 1912, and consequently this is the most up-to-date work on the subject. The price, by post, is 1s. 2d. (cloth, 1s. 9d.) from the Publishers, 148-9, Aldersgate Street, London, E.C.

Perpetual Carnation Society.

The society that devotes its attention to the encouragement and improvement of the perpetual-flowering carnation held its winter exhibition at the Royal Botanic Society's Gardens, Regent's Park, on Tuesday and Wednesday, December 5 and 6. The carnations were finely shown, and the whole exhibition was a success, speaking horticulturally, but there were very few visitors, the folks present being chiefly exhibitors and nurserymen who specialise in carnations. Moreover, the corridor and conservatory, especially the former, were uncomfortably cold for the greater part of the time covered by the show.

OPEN CLASSES.

In the open class for a group of cut carnations arranged on a space 10ft. by 3ft. there were three competitors, and the first prize, a gold medal, was won by Mr. W. E. Wallace, Eaton Bray, with a beautiful exhibit consisting of thirteen fine bunches of lovely flowers, associated with asparagus fronds, and set over a groundwork of ferns. Such varieties as Carola, Rose Pink Enchantress, May Day, Winsor, and Gloriosa well represented. Messrs. Allwood Brothers, Wivelsfield, Haywards Heath, were awarded second prize for a display that needed a few more bright-hued flowers to make it first-rate. Third prize fell to Messrs. Young and Co., Hatherley, Cheltenham, who had a very effective exhibit, and a well-arranged one.

Mr. Brunton's challenge cup for the best three vases of British novelties was secured by Mr. Bertie E. Bell, Guernsey, with Coronation, Judith, and Constance. For American novelties, three bunches, the American Carnation Society's cup was won by Mr. W. E. Wallace with beautiful blooms of Gloriosa, May Day, and the brilliant Scarlet Glow; Mr. Bertie Bell came second, and Messrs. W. Wells and Co., third. The Covent Garden Challenge Cup for one vase and one packed vase, each of flowers of two varieties, was won by Mr. W. E. Wallace, Eaton Bray, with exquisite examples of Dorothy Gordon and White Wonder; second prize fell to Mr. D. M. Collins, Heathfield Nursery, Swanley, and third to Mr. Phillip Ladds, Swanley.

In the series of classes for one bunch of twenty-five blooms there was a fair competition. For a vase of pink flowers, Enchantress style, Mr. W. E. Wallace scored with Enchantress in superb condition of size and colour, and to this vase was awarded the special prize as the best vase of flowers in the show. For pink flowers of the Mrs. Burnett style Mr. Wallace scored with May Day; while for rose-pink varieties Mr. Wallace was again first with Rose-pink Enchantress. In the Lawson class Mr. Bertie Bell scored with handsome flowers of Mrs. C. W. Ward; while in the white class Mr. D. M. Collins came to the front with beautiful flowers of Perfection. First prize for scarlet flowers was won by Mr. W. E. Wallace with Scarlet Glow.

The best self in other colours than those named was Mikado from Mr. A. F. Dutton, Iver; while for a vase of a fancy variety Mr. H. Burnett, Guernsey secured the premier award with effective flowers of the yellow-ground Mandarin.

For a registered variety not in commerce Mr. Wallace led with Una, a bright cerise variety that also secured an Award of Merit.

AMATEURS.

Mr. Usher, gardener to Sir Randolf Baker, Bart., M.P., Ranston, Blandford, secured the medal and first prize for a display of carnations arranged on a space 6ft. by 3ft.; he put up vases and stands of fine flowers, Enchantress, Britannia, Winsor, and White Perfection being especially good.

Mr. J. Bruce, gardener to Mrs. Bischoffsheim, won first prize for a group of carnations, and therewith secured the handsome cup presented by Lord Howard de Walden. Second prize was won by Mr. R. Barnett, gardener to Lord Furness, Grantley Hall, Ripon. Mr. Usher was first, and Mr. J. H. Bruce second for six pots of carnations.

For a case of Messrs. Stuart Low and Co.'s novelties, Mr. Usher scored, showing Lady Dainty, Lady Alington, Royal Purple, Rival, etc.; Mr. F. Norman, Much Hadham, Herts, second. Mr. Usher won the chief award for Mr. Burnett's novelties, and showed R. F. Felton, Mikado, and Pluto finely; in another class for Mr. Burnett's varieties Mr. Usher was equally successful. Mr. Usher scored for a case of twelve blooms, not less than six varieties, and here he had Carola, White House, Scarlet Glow, and Rose Doré in good form; Mr. A. R. Allan, gardener to Lord Hillingdon, Uxbridge, second.

In the small growers' section classes were provided for a vase of blooms of certain colours. Mr. Usher scored in the Enchantress class, but was beaten by Mr. A. R. Allan and Mr. Plowright in the Mrs. Burnett class, the first-named winning with Mrs. H. Burnett. In the rose class Mr. Usher scored with Rose Pink Enchantress; led in the white class with White Wonder; was first in the scarlet class with Britannia; was first in crimsons with Carola, and first for any other self colour with Rose Doré. Mr. Allan, Mr. Bruce, and Mr. Johnson, gardener to Lord Burnham, Hall Barn, Beaconsfield, won most of the other awards.

In the small growers' section some very charming flowers were displayed; three flowers of a variety were here required. Mr. G. H. Lawrence, Stratton, Godstone; Mr. J. Mackenzie, Plumstead; Mr. T. H. Plowright, Trinity Place, Windsor; and Mr. Kenyon Fuller, Sonning, were the leading prize winners in a brisk competition.

DECORATIVE CLASSES.

Mr. Wallace scored for a vase of three dozen blooms artistically arranged, and he showed May Day; Mr. H. J. Dudney, Erith, came second with Scarlet Glow, and Mr. Bell third with May Day. Messrs. R. F. Felton and Sons, Hanover Square, had the best bouquet of carnations, and were also easily first for a basket of carnations. Messrs. Felton and Sons were also winners of first prizes for three ladies' sprays and six button-hole bouquets, all composed of carnations.

First prize for table decoration of carnations fell to Mr. Usher, who used the variety May Day; Miss Muscutt, Wolverton, came second, and Mrs. A. R. Bide, Guildford Road, Farnham, third. In the open class for a table decoration Mrs. A. R. Bide won first prize with a capital arrangement of May Day; Mr. F. G. Bealing, Bassett, Southampton, second; and Messrs. Clarke and Cook, Castlethorpe, Bucks, third.

NON-COMPETITIVE.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, contributed a very fine display of carnations, and set up fine stands of May Day, Baroness de Brienen, Lady Alington, etc. (Gold Medal). Messrs. W. Wells and Co., Merstham, showed a few carnations and single chrysanthemums, and Mr. E. Guile, Newport, Essex, exhibited a new pink carnation named Lady Meyer, of very pleasing shade. Messrs. G. Fairbairn and Sons, Carlisle, gained an A.M. for Geisha, a large heavily fringed variety of deep heliotrope hue. Mr. Engelmann (Saffron Walden) and Mr. Clarke, March, conjointly showed a new crimson variety named Triumph, which secured a First Class Certificate.

Mr. G. Lange, Hampton, set up about a score of bunches of popular varieties of carnations (Silver-gilt Medal). Mr. G. Engelmann, Saffron Walden, had a very pretty display, wherein Carola, May Day, Harlequin (very bright yellow and scarlet fancy), White Wonder, Lady Northcliffe, Sunstar (yellow), Triumph, and Scarlet Glow were notably fine varieties (Gold Medal).

ANNUAL MEETING.

The annual meeting preceded by a dinner was held at Anderton's Hotel, Mr. J. S. Bruton presiding. The minutes of the previous annual general meeting being confirmed, the committee's report for the past year's work was read by the Hon. Secretary, Mr. E. F. Hawes. The Chairman, on moving its adoption, spoke of the important work in which the society was engaged, and hoped that much greater developments would take place during the coming year. After being duly seconded, the motion was carried unanimously. Mr. L. J. Cook, hon. treasurer, read the financial statement, which was also approved and adopted.

The following are the more important items in the report of the committee: Classes have been instituted for the encouragement of members resident over fifty miles from London, the committee agreeing to stage flowers sent to the exhibition. The Society's Year Book has been a great success. Sixty-three new members joined during the year, and thirty-four lapsed or resigned, the membership now standing at 301. The steps taken to ensure that no varieties raised in the British Isles would be considered for certificate or award unless registered, have proved most successful; the total number of British-raised varieties to date is 84. A working arrangement has been made with the American Carnation Society to prevent the duplication of names of varieties and its consequent confusion.

The financial statement showed a turnover of £201 3s. 4d. Subscriptions amounted to £111 2s. 6d., special prizes £22 4s., gate money £17 14s. 9d., sales of Year Book £9 7s. 6d. On the expenditure side prominent items were, £98 19s. 6d. for prizes and medals, £35 1s. 6d. for printing and stationery, and £18 9s. 3d. for postages. The society has now £25 on deposit, and carries forward a cash balance of £3 0s. 5d.

A hearty vote of thanks was accorded the retiring officers and committee for their valuable services during the year, and an altera-
A letter was read from Mr. H. Mathias
tion of rule, increasing the number of committee from 18 to 20 members, was adopted.
regretting his inability to attend owing to severe illness, which also necessitated his resignation as hon. secretary, a position he has held since the formation of the society, and, jointly with Mr. Hawes, for the past two years. As a mark of appreciation of the able services rendered by Mr. Mathias, the committee unanimously elected him a vice-president of the society, and instructed Mr. Hawes to write on their behalf expressing a hope that Mr. Mathias would have a speedy and complete recovery to health.

The following officers were elected for the coming year: Lord Howard de Walden, president; the whole of vice-presidents, with the addition of Messrs. Mathias and F. C. Harwood; Mr. J. S. Brunton, chairman of committee; Mr. W. E. Wallace, vice-chairman; Mr. L. J. Cook, hon. treasurer; Mr. E. F. Hawes, hon. secretary and show superintendent; and Mr. Richard Pinches, auditor. The following gentlemen were elected to serve on the committee: Messrs. W. H. Page, H. F. Mason, H Matthias, G. H. Lawrence, M. C. Allwood, Mairbairn, S. Mortimer, A. R. Allan, Usher, T. Weston, W. Wells, jun., Shaw, Metcalfe, Jordan, Sherwood, Lawrenson, Zaudevin, and Kirkwood.

A vote of thanks to the chairman concluded the proceedings.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE.—December 5.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair); Dr. A. B. Rendle, F.R.S., Messrs. G. Gordon, V.M.H., A. Worsley, W. Fawcett, G. Wilson, J. O'Brien, V.M.H., W. C. Worsdell, and F. J. Chittenden (hon. secretary).

THE LATE MR. JAMES DOUGLAS.—It was unanimously resolved to convey a vote of condolence to Mrs. Douglas on the death of Mr. James Douglas, who had for many years been a member of the Scientific Committee.

DOUBLE ODONTOGLOSSUM CRISPUM.—Mr. Gurney Wilson, on behalf of Mr. Jensen, showed a double flower of Odontoglossum crispum. The two outer whorls were normal, but the stamens had apparently developed and become petaloid. The plant showed the same peculiarity each year.

GALLS ON RIBES ALPINUM. — Dr. Rendle exhibited a branch of Ribes alpinum from near Grantham, in Lincolnshire, having large numbers of black galls upon it about three-eighths of an inch to one inch long so numerous that the whole bore a superficial resemblance to a small branch of larch bearing numerous small cones. The cause of the production of these galls was unknown.

UNCOMMON FRUIT.—Mr. George Gordon exhibited a ripe fruit of Holboellia latifolia (Stauntonia latifolia) from a wall at Somerleyton Hall, where it had not been known to fruit before.

ABERRATIONS OF SAXIFRAGA LIGULATA.—Mr. W. C. Worsdell showed specimens of leaves from a plant of Saxifraga ligulata at Kew which, season after season in the autumn, produces leaves of ascidia form and developed in different degrees. Many of the leaves showed cresting as well.

VIOLETS WITH BRANCHED PEDUNCLES. — He also exhibited violets with branched peduncles from Mr. Williams. The specimens were sometimes branched low down and sometimes so near the flower, that two double flowers were developed almost touching one another.

Horticultural Club.

On Tuesday, the 5th instant, the usual monthly dinner of this club was held at the Hotel Windsor, under the chairmanship of Mr. Harry J. Veitch, a considerable number of members and guests (including ladies under the new regulations) attending. After the dinner, as is customary, a lecture was delivered, this time by Mr. Arthur W. Sutton, J.P., V.M.H., entitled, "Four Hundred Miles on Horseback East and West of the Jordon." The lecture was illustrated by means of 100 beautifully coloured views of the Lebanon, Gilead, Basham, Moab, and Southern Palestine, and was intensely interesting, as most of the views had been taken by Mr. Sutton himself, who described them seriatim, adding the experiences, difficulties, and adventures which accompanied their taking, together with the habits and customs and industries of the Arab Jews and other inhabitants of the district traversed by him and his party under the care of Messrs. Cook and Sons. As Palestine is only about 150 miles from north to south, the first slide was a map of that country upon which he indicated the tortuous route which the 400 miles involved, embracing, of course, the many points of salient interest which the plan included. As the scene of innumerable scriptural references, Mr. Sutton increased the interest of most of the slides by briefly alluding to these, indicating now and then how a visit to the actual localities dissipated critical doubts which had been raised, by confirming instead of confuting. The many magnificent ruins of ancient temples of Roman, Greek, and still older periods, which indicate the presence of large populations where now lies a practical desert, were shown on the screen to great advantage, and among these, undoubtedly, the most curious and interesting were those of Derea. Here there are at least four cities superposed the one above the other. The present Arab buildings are founded upon a Græco-Roman city, which, in its turn, stands on the remains of a still older one in which bevelled stones are used; while below these three there is a treglodyte city entirely excavated in the native rock, the subterranean residence of King Og, to whom the Scriptures refer in many places. This subterranean city consists of a labyrinth of streets with shops and houses, and a market place, but is hardly safely accessible to foreigners. A reference to the Dead Sea, which, however, only appeared in the distance in one of the views, related to the curious fact that it is no less than 1,300 feet below the level of the Mediterranean, and forms the lowest lying body of water on the earth's surface. It was computed that about six million tons of water pour into it daily, the whole of which is evaporated, as there is obviously no outlet; its excessive saltness is therefore the outcome of accumulation from the Jordon of the minute quantity of salt in its waters. From the Dead Sea to Jerusalem there is a rise of nearly 4,000 feet, as that city is about 2,500 feet above sea level. The Jerusalem of Christ's time lies about 100 feet below the level of the present city, and in this connection and others the lecturer alluded to, and showed some slides of, the valuable work effected by the "Palentine Exploration Fund," which has been busy for forty-five years in bringing to light the many buried treasures of Palestine. After the lecture, Sir Charles Watson, chairman of the fund in question, who has long devoted himself to these operations, and Mr. Harry J. Veitch, spoke in high terms of the lecture, and a very hearty vote of thanks concluded the meeting.

National Chrysanthemum Society.

At the meeting of the Executive Committee held recently at Carr's Restaurant, Strand, Mr. Thos. Bevan presided. After reading the minutes and various correspondence, the Secretary was authorised to sign the contract with the Crystal Palace for the N.C.S. Show of 1912. The Rochford and District Society applied to be admitted in affiliation, and the same was agreed to. After considering a question of interpretation from the Alsayer Society, the financial statement to date was read, showing a satisfactory working balance.

It is pleasant to be able to record that cheques for all prize money awarded at the November show were sent off to the winners two days after the show was held.

The Chairman of the Floral Committee referred to the meeting held on November 20, which, he thought, constituted a record; 106 novelties were staged; of these fourteen were awarded F.C.C., sixteen were commended, and four were asked to be seen again. There was one award for colour. The committee passed a special vote of thanks for the generous way in which the trade had supported the society at the October and November shows.

New members were elected, ten at a guinea, three at half a guinea, and twenty at 5s. Mr. Harman Payne was asked for a report on his recent visit to the French chrysanthemum shows.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

BEGONIA GLOIRE DE LORRAINE.—W. F., Chippenham: This famous begonia was raised by Mons. Lemoine, of Nancy, France, and its parents are Begonia socotrana and B. Dregei. The "rust" that sometimes appears on this and other begonias is due to the presence of a tiny mite. The mites eat into the leaf substance, usually on the under-surface or close to the leaf-stalk, and so produce the rusted appearance. Dusting with tobacco powder is a good remedy, while dipping in a nicotine solution and regular fumigation are preventives.

BACTERIA ON PLANT ROOTS.—F. R. C., Epsom: Leguminous or food-bearing plants have the power, with the aid of certain bacteria, of obtaining free nitrogen from the air for use in the upbuilding of their structure and the perfecting of their seeds. The nodules on the roots of leguminous plants are the homes of these useful bacteria. The cycas and some few other plants have also the same power and assistance, and a few years ago it was thought palms should be added to the list of plants which carry colonies of domesticated nitrogen-collecting bacteria. Symbiotic relations also exist between these nitrifying organisms and podocarpus and alnus.

PERMANENT WHITEWASH.—S. C., Rawtenstall: There are now so many good permanent washes on the market, white, or in colour, that it is probably not worth while to mix one's own material. However, we give you an American recipe, and one that has appeared before in these pages. Take a half-bushel of freshly burnt lime, slake with boiling water, and cover during the process; strain through a fine sieve or cloth, and add seven pounds of salt previously dissolved in warm water, three pounds of rice flour boiled to a thin paste, and stirred in boiling hot, half a pound of powdered Spanish whiting, and one pound of glue previously dissolved in the usual way. Add five gallons of hot water and stir well; then let the mixture stand, carefully covered, for a few days, when, after re-stirring it and making it quite hot, it will be ready for application. It is important that the lime be fresh and slaked with boiling water.

KALANCHOE FLAMMEA.—J. M. W., Lincoln: Kalanchoe flammea is a native of Somaliland, and seeds of it were received at Kew in 1895, the resulting plants flowering at the Royal Gardens for the first time in 1897. Not only is the species a valuable conservatory plant, but it is largely grown for market.

FAILURE WITH BEGONIAS AND CYCLAMEN.—H. B. A., Kent: The knotted roots are caused by eelworms, and if the comparative failure of the plants in previous years has been brought about by similar conditions, you had better sterilise the soil for future batches. This means raising the temperature of the soil to boiling point by placing it on sheet iron over a fire, or in a brisk oven. Where there is any possibility of trouble of this kind the soil should always be sterilised before use; the plants will not grow quite so vigorously at first in sterilised as in non-sterilised soil, but they soon make up for lost time, and will, ere long, get ahead.

INJURED VIOLETS.—V., Sunningdale: The soil and roots of the violets sent give us no clue to the cause of the trouble; the former is good, and the roots show that they like it. We believe that some injury was done to the crowns at the time of planting; there may have been a bruise such as would be caused by an unskilful handling of the trowel, or from letting the collar of the pant lay on the sharp edge of a box during conveyance from bed to frame. Such weakness would only show when the plants commenced to flower, and to be subjected to the trying conditions of frame culture. That only a few plants have suffered at once suggests some such cause as this; when fungoid diseases attack violas in frames, practically every plant is affected more or less.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

X. Y. Z., Barnet.—1, Maxillaria picta; 2, Oncidium flexuosum; 3, Selaginella Emileana; 4, an Asplenium, send fertile frond; 5, seedlings of Cyrtonium falcatum; 6, Gasteria verrucosa.

C. B., Saffron Walden.—

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without those it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

E. J. P., Southampton.—Gravenstein.

L. H. A., Gloucester.—Sturmer Pippin.

J. T. A., Bethersden.—Probably Dutch Mignonne.

G. P. J., Blandford.—Not a good specimen; probably Hubbard's Pearmain.

H. H., Harrow.—1, King of the Pippins; 2, Emperor Alexander; 3, Herefordshire Beefing.

E. C. H., Hastings.—1, Vicar of Winkfield; 2, Josephine de Malines; 3, New Hawthornden.

A. C. W., Broxbourne.—1, Pitmaston Duchess; 2, not recognised; 3, probably Margil.

W. P., Canterbury.—Pears: 1 and 2, Beurre d'Aremberg; 3, not recognised; Apples: 1, not recognised; 2, Cox's Orange Pippin.

FORTHCOMING ENGAGEMENTS.

MONDAY, December 18.—National Chrysanthemum Society, committee meeting at Essex Hall, Strand, at 7 p.m.
TUESDAY, December 19.—Royal Horticultural Society; there will be no exhibition on this date, but the committees will meet to consider novelties at 12 o'clock.
WEDNESDAY, December 20.—Royal Meteorological Society.
THURSDAY, December 21.—Linnean Society.
MONDAY, December 25.—Christmas Day.
TUESDAY, December 26.—Bank Holiday.
THURSDAY, December 28.—National Horticultural Society of France.
Manchester and North of England Orchid Society.

Cytisus filipes.—This greenhouse broom, which is a native of Teneriffe, flowers more or less during the winter and early spring. It is widely removed from the popular Cytisus racemosus, which forms a dense growing bushy plant, while in Cytisus filipes the shoots are long and slender, and practically devoid of foliage. In the case of a tall specimen they hang down for a considerable distance, and form a very graceful feature. The absence of leaves is not so apparent as the bark of the shoots is green. The flower are white.—W. T.

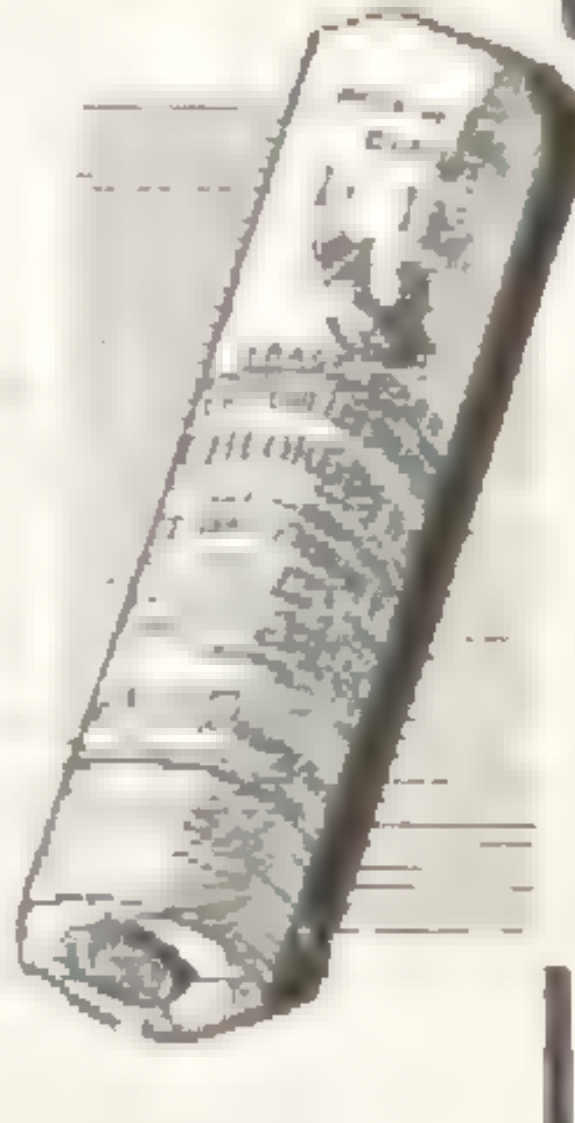
Dr. J. Collis Browne's

Chlorodyne



Universally acknowledged to be the Most Valuable Medicine known, and one which should be in every home.

THE BEST REMEDY FOR

COUGHS, COLDS,

ASTHMA, BRONCHITIS.

Cuts short all attacks of Spasms, Hysteria, and Palpitation.

The only Palliative in Neuralgia, Toothache, Gout, Rheumatism.

Acts like a Charm in DIARRHŒA and DYSENTERY.

Insist on having **Dr J. COLLIS BROWNE'S** Chlorodyne, *The Original and Only Genuine.*

Convincing Medical Testimony with each bottle.
Of all Chemists, **1/1½, 2/9, 4/6.**

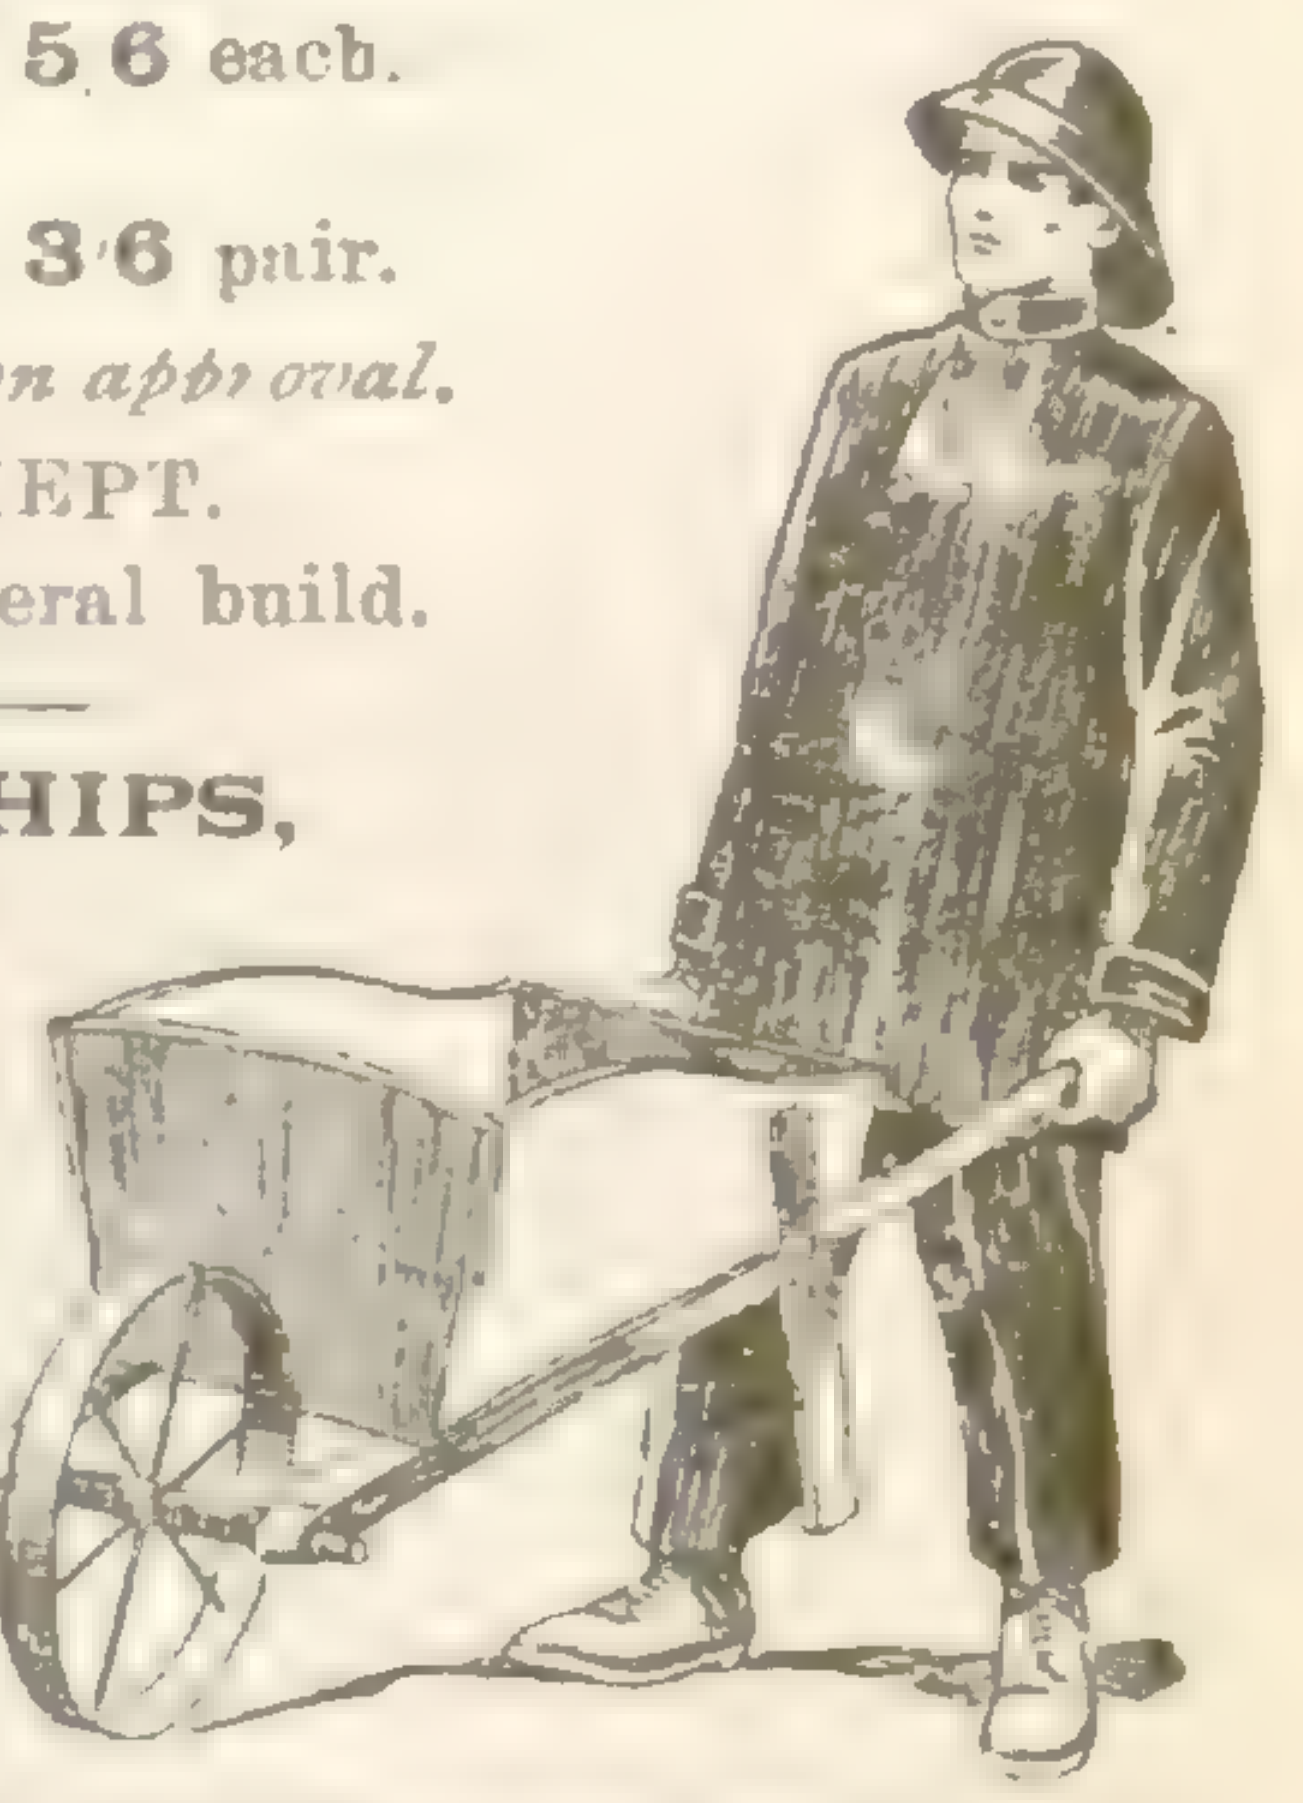
ORCHIDS

EIGHT MILES BY ROAD FROM THE CITY.

A visit of Inspection invited of our well grown stock of Thousands of **CATTLEYAS, DENDROBIUMS, ODONTOGLOSSUMS,** and an endless variety of Choice **ORCHIDS.** Nurseries easily reached by Rail to BUSH HILL PARK Station, or by Road.

Telephone:—Enfield, No. 1 and 2.

STUART LOW & CO., Royal Nurseries, BUSH HILL PARK, MIDDX.



Sou'westers, 1/6 each.
Oilskin Jackets, 5/6 each.
Overalls, 2/6 pair.
Felt-lined Clogs, 3/6 pair.

Any of the above sent on approval.

ALL SIZES KEPT.

State height and general build.

QUASSIA CHIPS,
FOR FRUIT & FLOWER SPRAYING,
in 28 lb. bags, **5/6.**
All Goods Carr. Paid

CHRYSANTHEMUMS.

THE BEST 12 JAPANESE EXHIBITION NOVELTIES OF 1911.

Countess Granard, Mrs. G. Drabble, Mrs. A. Herbert, H. E. Converse, D. B. Crane, Mrs. G. C. Kelly, Queenie Chandler, F. T. Mew, F. C. Chandler, Marie Loomes, Mr. Turner, Harry Wood.

Strong plants of the above—or purchaser's option of other 1911 varieties—**1/-** each, **10/-** the dozen; 3 of each for **25s.**; delivered early spring. Unrooted cuttings also supplied as per catalogue.

THE BEST 6 NEW EXHIBITION SINGLES OF 1911.

Charles Dickens, Charles Kingsley, Miss May Thorne, Snowflake, Mrs. W. Higgs, Mrs. Trenham Gilbey.

Plants in early spring, **1/-** ea.; the 6 for **5/-**; or 3 of each, **12/6.** Cuttings one-third less.

NOVELTIES FOR 1912.

JAPANESE: His Majesty, magnificent crimson; **Gorgeous,** rich deep yellow; **Mrs. J. H. Cocken,** beautiful bright yellow; **Miss Beatrice Hoar,** distinct crimson; **Mrs. T. Brooke Edwards,** salmon-buff; **Miss Gladys Herbert,** beautiful mauve; **Amber Queen,** rich amber and terra-cotta. All being distributed from these Nurseries. For further particulars, also for New Incurveds and Singles, see Novelty List, now ready.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

Seedless Fruits.

The very term, seedless fruits, from the scientific point of view, involves a contradiction in terms, since, properly speaking, the seed itself is the true fruit, and what is popularly known as the "fruit" is a mere adjunct thereto, evolved to assist that seed in one way or another in its dissemination. To this end we see the seeds associated in innumerable ways with fleshy pulps of many kinds and many flavours sweet or acid, as with oranges, lemons, apples, pears, and in short all the succulent dessert fruits with which we are blest in these days, and in which connection, from the dessert point of view, the seeds are regarded as things to be avoided rather than appreciated. This being so, the selective cultivator has devoted all his attention to the improvement of the pulp alone, and, as is ever the case when plants are induced to grow abnormally strongly in one direction, it is at the expense of growth in another, the result has been that in some directions, such as seedless oranges, bananas, grapes, cucumbers, etc., the seed has entirely, or almost entirely, been suppressed, while in many other fruits the number of seeds has been greatly reduced, and their vitality impaired. Thus the few pips we shall find in choice apples and pears can by no means be compared with the number present in wild fruits. The curious point in this connection is that Nature should so far lend herself, as it were, to such a frustration of her own primary object, i.e., the creation of seed for reproductive purposes, as to enable man, through the fertilising pollen, to start the development of the seed plus its quite secondary attractive pulp, and then, to honour him sufficiently, to drop the primary object entirely, or almost so. This she does by limiting herself to the production of what has been rendered objectless, so far as she is concerned, since the pulp by itself is absolute waste from the reproductive point of view. Once indeed a plant has lost its seed-bearing capacity its doom is sealed so far as Nature is concerned, since its individual existence terminated it can leave no successors. It is, indeed, in the direction of cultivated fruit that we see some of the most remarkable results of diverted energy, since therein we see an immense increase in bulk and attractiveness of the luscious pulps and sweet flesh destined by the cultivator for human enjoyment alone, which involves the minimum of chance of its fulfilling its primary object as an assistance to seed dissemination, and it may be germination when it reaches the soil, while at the same time, the energies of the fruit-bearing plants are so largely taken up in this direction that the seeds are much reduced in number, or even suppressed entirely. On parallel unnatural lines we may advert to the beautiful double-flowering plums and cherries which nowadays embellish our parks and gardens in the spring. Here we see plants, robust and healthy, which, from the point of view of Nature, have gone altogether wrong in another direction by devoting all their seed-producing energies to the production of bunches of useless rosy petals, which in their primary simple form of single flowers were designed to attract the insect world for fertilising purposes connected with the all-important seed which has now been absorbed in favour of barren flowers. In all these cases man has contributed by his selection on unnatural lines to absolute inversion of natural selective laws, which Nature would very speedily set about revenging, were these artificial products turned adrift and left to her untender mercy. Man, however, might well retort that Nature has set him the example, since every now and again she spontaneously produces "imitations" or "sports" of an unfertile character, but which by their imperfection can never become elevated to specific rank, since they belong to the unfit, and have therefore but a transient career in the evolutional scheme. In this particular connection, claiming the seed to be the fruit proper, we may legitimately advert to the sugar cane, which was cultivated on an enormous scale for a very long period as a presumed barren or seedless plant, until careful search, instituted by Sir Daniel Morris, led to the discovery that seed was occasionally sparsely produced. This discovery, permitting as it did of seminal reproduction for the first time, led in its turn to selective cultivation, which promises to lead to such great improvements, both quantitative and qualitative as to entirely revive the moribund sugar industry of the West Indies, by virtue of the redemption of the sugar cane from the stigma of a seedless plant.

MR. MONTAGU C. ALLWOOD.

Mr. Montagu C. Allwood.—Though young in years, Mr. M. C. Allwood is old in experience so far as the perpetual-flowering carnation is concerned, and he is recognised as holding a foremost position among the raisers and growers of this very popular class of flowers. Quite recently Mr. M. C. Allwood has joined forces with his brother in the arrangement of a nursery devoted entirely to carnations, at

Wivelsfield, Haywards Heath, Sussex. In his earlier years Mr. Allwood spent some time with the Messrs. Illman, at Lincoln, and then, coming South, entered the service of Myatt's Horticultural Company, Swanley, presently passing on to Mr. Philip Ladds' place at Swanley Junction. From Swanley he went to Edmonton, and was employed at Messrs. H. B. May and Sons' establishment. His next move was to Messrs. Clibran's, at Altrincham, and then he came South again, to Enfield, where, first with Messrs. Hugh Low and Co. and then with Messrs. Stuart Low and Co., he spent seven years. Mr. Allwood has written a book on "Perpetual Carnations," has invented a carnation support, and contributed carnation notes to these pages. He has an extremely optimistic temperament, and unbounded faith in the future of the flower with which his life work has been chiefly concerned.

The Gardeners' Magazine Almanack.—Conjointly with the first issue (January 6) of the Gardeners' Magazine for the New Year, we shall publish our Almanack for 1912, which, as in previous years, will be supplied with each copy free of cost. The Almanack will be of double-sheet size, be attractively printed in colours, and will contain the dates of all the important exhibitions and meetings arranged for the year. The contents of the issue will be of special interest, and, as a large additional demand is expected, we advise those of our readers who require extra copies to give their orders early, and thus avoid the risk of disappointment.

Funeral of Sir Joseph Dalton Hooker. — The funeral of Sir Joseph Hooker took place at Kew on Friday, December 15, his remains being interred in the family vault, where his father was buried. The service was conducted in Kew Church by the Rev. W. H. Bliss, Mus. Bac., Hon. Chaplain to the King, Rev. A. Ogilvy, and the Rev. A. G. Musgrave, Rector of Wndlesham. The church was well filled with mourners, and those who had come to pay respect to the memory of a great scientist, and, in addition to Lady Hooker, Dr. Chas. Hooker, Sir William Thiselton Dyer, and other members of the family, there were present members of many learned societies, while those representing botany and horticulture included Professor Bayley Balfour, Dr. D. H. Scott, Sir Daniel Morris, Professor W. W. Watts, Dr. Daydon Jackson, Mr. Harry J. Veitch, Professor Bower, Lieut.-Colonel Prain, Mr. E. G. Baker, Lieut.-Colonel Strachey, Professor Sir G. Darwin, Dr. Francis Darwin, Professor S. H. Vines, Professor Frank W. Oliver, Dr. A. Henry, Dr. A. Gunther, Dr. Boulger, Dr. D. Oliver, Mr. George Gordon, Mr. R. Hooper Pearson, Dr. Stapf, Mr. W. Watson, Mr. W. Goldring, Mr. A. R. Rolfe, Mr. A. E. Brown, Mr. Hill, Mr. C. H. Curtis, Mr. Harvey, Mr. W. Irving, Mr. Coutts, and Mr. Osborne. Though not actually shut during the time of the funeral, the gates of the Royal Gardens, Kew, were closed as a sign of respect for a past Director, but, though closed, they were at once opened to anyone presenting themselves for admission.

Market Gardeners Compensation.—The text of the Market Gardeners' Compensation Bill, presented by Mr. Eyres-Monsell, and supported by Mr. Courthope, Mr. Pollock, Sir Luke White, Mr. Charles Bathurst, Sir Ivor Herbert, Sir John Rolleston, and Sir Courtenay Warner, has been issued. A memorandum accompanying the Bill states that the recent decision of the Court of Appeal in Kedwell v. Flint has deprived a large number of market gardeners of their right to compensation, and consequent security for capital, which the Market Gardeners' Compensation Act, 1895, was intended to secure, and up to the present time has actually secured, for them. The object of the Bill is to restore to market gardeners the right to compensation, and the security which they have enjoyed for sixteen years, and have now lost. The Bill is supported by the Central Associated Chambers of Agriculture, the National Federation of Fruit Growers, and the Market Gardeners' Association.

Bushey Park.—A Royal warrant has been issued authorising the appropriation of part of Bushey Park for allotments for the benefit of the parish of Hampton. The land is being divided into plots of ten rods each, and the applications already received are more than sufficient for the area available. The provision of a new entrance to Bushey Park at Hampton Hill has been sanctioned by the Board of Works.

The Gardening Year Book for 1912, is now published, and may be obtained direct from the Publishers of the Gardeners' Magazine, 148 and 149, Aldersgate Street, 1s. 3d., post free, or through any bookseller or newsagent. We shall take advantage of an early opportunity for referring to its contents, but for the present it must suffice to say that the high standard which has placed it in a unique position among annual publications associated with horticulture is fully maintained.

New Park for Shadwell. — At the meeting of the London County Council on Tuesday a joint report was received from the Parks and Open Spaces and Improvements Committee, recommending the Council to co-operate with the King Edward Memorial Committee in acquiring the Shadwell Market site and converting it into an open space. The City Corporation are the freeholders of the site, and are willing to transfer their interest for about £70,000, provided that the site is acquired for the purposes of a memorial. The London County Council holds from the Corporation a lease of a part of the property, at a rent of £710 a year, which has fifty-five years to run. The Memorial Commitee suggested that the London County Council should, as its contribution, capitalise its liability under this lease and agree to the property being incorporated in the proposed open space. The Corporation is prepared to accept the sum of £14,000 as the capitalised value, and the joint report recommend the Council to approve the expenditure, and offer to undertake the maintenance of the park for the use of the public. The report was adopted unanimously.

Preservation of Cut Flowers.—The advice which Mr. T. Stevenson gives on the cutting of the flowers of sweet peas is of so high a degree of value, not only in relation to the flowers with which he is dealing, but to cut flowers generally, as to fully justify special attention being directed to it. Mr. Stevenson advised that when the sweet peas are cut the flower stems should at once be put in water and remain therein for one or more hours, and stated that flowers so dealt with would retain their freshness for twenty hours or so after being removed from the water and packed in basket or box, and then conveyed several hundred miles by train. Many of our readers might say that there is nothing new in placing the stalks of flowers in water immediately they are cut, and allowing them to remain there for some time, for it has long been practised by market growers, and we have recommended the practice on numerous occasions, but these facts do not in the slightest degree detract from the importance of the advice given by Mr. Stevenson. The practice has not, however, become general, and we trust the simple method of procedure advised by this skilful cultivator and exhibitor will receive the attention it merits and be generally adopted.

Certificating Gardeners. — At the meeting of the North of England Horticultural Society, held at Leeds on the 13th inst., a motion, proposed by Mr. F. C. Puddle, seconded by Mr. P. Clapham, and supported by Mr. W. Cuthbertson, that "At the request of the gardener, and by permission of the owner of the garden, the N.E.H.S. send a deputation to consider the granting of a certificate to the head gardener, who has been responsible for the work of the garden for at least three years," was lost, an amendment, proposed by Mr. J. F. Donoghue, and seconded by Mr. J. P. Leadbetter, that, "the matter be indefinitely postponed," being carried by a small vote. A considerable number of the members had left for home when the vote was taken.

Hardy Shrubs Flowering in Winter.—The hardy shrubs that produce their flowers during the winter months are more numerous than is generally considered to be the case, a fact of which we are reminded by a gathering of flowers received from Mr. W. A. Cook, head gardener at Leonardslee. Among the specimens are sprays of Jasminum nudiflorum; the flowers of exceptional size and colour; Colletia Bictonense, a distinct and interesting evergreen shrub; Choisya ternata, rather out of season, perhaps, but the fragrant white flowers are nevertheless most acceptable; Erica lusitanica, a distinct and beautiful species producing a profusion of pure white flowers; E. carnea, also free in blooming and most attractive; Azara integrifolia, a handsome evergreen shrub, bearing with great freedom clusters of small greenish flowers; Chimonanthus fragrans grandiflora, so well known for the fragrance of its blossoms. A short time since we received from the Wych Cross gardens sprays of several of the species of Osmanthus which are of interest for their flowers as well as their other attractions. Especially noteworthy for flower production are O. ilicifolius, which has foliage resembling that of the common holly, and O. myrtifolius, which, as indicated by its specific name, has myrtle-like leaves. Both species, when they have attained some age, produce large numbers of small white flowers along the growths, these flowers being delightfully fragrant.

Honour for M. Victor Lemoine.—The trustees of the Massachusetts Horticultural Society have awarded the George Robert White medal of honour for the current year to M. Victor Lemoine, of Nancy, France. This medal is awarded annually to the person who has done the most during the year, or in recent years, to advance the interest in horticulture in its broadest sense. The award for the year 1911 is eminently appropriate as a recognition of the accomplishments of M. Lemoine in the production of so many varieties of flowering plants and shrubs which have become of permanent value to the horticultural interests of the United States, as well as of Europe. If he had done nothing more than to give to the world Begonia Gloire de Lorraine, he would have merited the award; and, in addition, his numerous other introductions have made the name of Lemoine a familiar one to all horticulturists. This is the third award of the George Robert White medal. It was founded by Mr. White in the year 1909, when the first award was made to Professor Charles Sprague Sargent, director of the

Arnold Arboretum, of Boston. The award for 1910 was given to Jackson Thornton Dawson, also of Boston, and well known throughout the United States as a skilful plant man. The medal now crosses the ocean to convey America's appreciation of what France has done in the interest of horticulture.

Action for Payment of Prizes. In Huntley Small Debt Court, Sheriff Dudley Stuart heard a case in which an exhibitor sued the Strathbogie Horticultural Society for delivery of certain prizes, alleged to have been won by him at the society's summer show. The solicitor who appeared for the plaintiff said that he was a competitor, and was awarded certain prizes by the judges. The committee, however, having received a protest against the plaintiff's exhibits disqualified him, and the action was the result. The solicitor for the society read the rules to show that the committee had acted in accordance with them. On the other side, it was contended that the rules did not give the committee the power to disqualify a competitor after the judges had given their decision. The Sheriff held that the rules of the society gave the committee the powers they claimed in this case, and decided in their favour, with costs.

National Chrysanthemum Society. The following are the dates of the shows and meetings of this society in 1912: Early Autumn Show, October 2 and 3, and Autumn Exhibition, October 29, 30, and 31, both at the Crystal Palace. Meetings of Executive Committee, at Carr's Restaurant, Strand, at seven p.m., excepting the February meeting, which will commence at six p.m.; January 15, February 19, September 23, October 21, November 18, and December 16. Meetings of Floral Committee, September 9, seven p.m., Carr's Restaurant; September 23, three p.m., Essex Hall, Essex Street, W.C.; October 2, one p.m., Crystal Palace; October 21, three p.m., at Essex Hall; October 29, one p.m., Crystal Palace; November 11, three p.m., Essex Hall; November 20, three p.m., Essex Hall; December 2, three p.m., Essex Hall. An Exhibition and Conference will also be held at Essex Hall, Wednesday, November 20. The annual meeting will be held February 5 at Carr's Restaurant, seven p.m.

Wages of the Edinburgh Botanic Gardens Employees.—The members of the Edinburgh Royal Botanic Gardens Employees' Union have sent a memorial to the Right Hon. the Earl of Beauchamp, First Commissioner, H.M. Office of Works, drawing attention to the difference in the wages paid to the staff and those paid in London parks and gardens. It states that in spite of the increased cost of living, which is as expensive as it is in London, the wages have not increased in proportion. The young men in the gardeners' and foresters' department, for instance, receive 21s. weekly, and pay from 14s. to 15s. for their lodgings, exclusive of extras. The skilled labourers receive 24s. weekly, and the unskilled labourers 21s. After three years' service the latter are supposed to be skilled labourers, but the memorial states that there are several men in the gardens who have this qualification, but have not received an increase. Attention is also drawn to the wages of the park keepers, who receive 22s. to 25s. weekly.

Conference on Dahlias. In accordance with the practice which has obtained during the past two years, the National Dahlia Society will, we understand, hold a conference early in the spring of 1912. The date has yet to be fixed, and the programme to be settled.

ROSE GROUPING FOR COLOUR.

Colour makes the character of a garden. No matter how fair the formation the whole effect will not please unless the mysterious harmonies and contrasts of which hues are capable have been well balanced and exhibited. A cold, sad garden is one in which there are few warm tints, but a preponderance of white, lavender, pale blue, and silver, or grey foliage, and the presence of white or gray walls can so add to this error as to make the spot positively depressing. Sunshine is golden, true, whether it falls on a melancholy scene or a cheering one, but it loses half its glory unless there are ruddy masses of blossom in the pleasure grounds, and up the brickwork that is the shell for a home.

When considering how to use roses for their colour value only we come face to face with many truths to put in practice. No varieties should be chosen for their size of bloom alone, nor yet for their excellence for cutting. Whether the shape is globular or pointed, the petals numerous or few, the centre visible or veiled, is of little consequence. The merits to be looked for are freedom and long continuance in the output of vivid or delicate flowers, and these must be well revealed. A rose that droops on thin stems, as though trying to hide its beautiful heart, should be passed by; so, too, should those which bury their blossoms among the too luxuriant foliage sprays, or which change in hue with every hour of life. As a rule, roses of composite colour are much less effective than those in which one tint is spread over all the petals; an exception is the Lyon rose, for in this the chrome yellow base so shades into the shrimp and sherry-red that the whole appearance is a deep salmon, unique, it seems, in the rose family. A bed of this, on a verdant velvet lawn, is surely one of the unsurpassed beautiful features of any garden.

Self beds of roses can always be advised, but then we are confronted by the necessity for well grouping the beds. It is not enough to keep varieties distinct, for the effect of a lawn, or gravel square, in which several beds are set, has to be estimated altogether. A gardener who has mastered only the elements of colour art will separate pink from salmon, and carmine from scarlet, yet allow these discordant hues to occupy positions from which they can see one another.

Vermilion is one of the most difficult colours to group, but also one of the most lovely. There are some shades of salmon that tone into it, as though an artist had simply mingled white with the vermilion pigment, and so obtained a diluted form of it. Two of the most opposed roses possible to name are L'Ideal and Cheshunt Scarlet, yet many catalogues describe them simply as "red." Either may be admirably placed near buff roses, of the type of Gloire de Dijon and Madame Bérard.

Deep pink roses can be set off best by snow-white ones. If cream are introduced near, all the bluish or lavender shadings in the pink are so intensified by contrast as to give the blossoms a dull, heavy look that they need never wear. Cream should be kept to accompany apricot, of which they are really but a paler shade. Another secret is that salmon roses, such as Madame Abel Chatenay, Lady Waterlow, and Countess of Gosford, the last having a yellow base, are seen to perfection in juxtaposition to lemon varieties, which may be exampled by Madame Hoste, Céline Forestier, Aglaia, the yellow Rambler, and Isabella Sprunt, to mention old varieties known to all rose-lovers.

One possibility too seldom realised is the planting of lawn beds only with the darkest crimson and maroon roses. This unique arrangement attracts great admiration, and nowhere but on turf are these hues sufficiently shown up by the green they need. The leaves of varieties of deepest crimson do not give the grass-green that brightens their ruby petal shadings by contrast.

There are numbers of coppery roses now, but very few that can be safely mingled in bed or border. These should be carpeted beneath by pinks, or other plants with silvery foliage.

M. H.

CLIMBING ROSES.

White Lady will, I hope, not object to a few additional notes on the interesting selection of climbing varieties (see p. 933). Madame Alfred Carriere is quite one of the best of roses, grown here amongst many, for a pergola or a pole; it is the earliest to open its freely-expanding blossoms, and its delicate pink-tinted blooms are always admired either on the plant or in a cut state. It is a variety specially immune from mildew and aphis attacks, and in growth it is free, sending up stout sucker-like shoots, which are quite the best suited for freedom of flower. In a selection of climbing roses this variety can safely be given premier position, and what more can anyone say in favour of any rose?

Ards Rover for a south wall, either low or high, is particularly well suited, as it is amenable to both forms of treatment, bearing quite restricted pruning, when once the allotted wall space is covered. A close method of spur-pruning may annually be practised with great success. This is one of the earliest roses to open its flowers, and in the bud and half-open state no variety can excel it, especially for its perfume. The foliage, too, is robust, dark green in colour, and forms a fine contrast with the brilliantly-coloured flowers.

Climbing Caroline Testout is a good rose, but it should not be allowed to ramble too high without occasionally cutting back to induce vigour, as, without this, the plants are liable to become weak and leggy. I have in mind a dozen plants growing in a nursery for the sake of flowers and stock buds. These are cut each year to within 7ft. of the ground, and very well do they succeed. If another pink of a similar character is required, Climbing La France can safely be planted, as the blossoms are freely produced, and are more shapely than those of Caroline Testout.

Climbing Aimée Vibert is so excellent in growth, flower, and perfume that it seems almost a pity to say one word against its inclusion; but the fact of its holding its dead blossoms so long in the forks of the huge trusses gives it an unsightly appearance. To the list I would like to add Tausendschon (Schwartz, 1906), which is not grown out of doors nearly so much as its merits deserve. Last summer, during the extreme hot weather, the blooms on this variety lasted longer in a fresh condition than those of any other rose in the garden; indeed, the bright sun seemed to emphasise the colour. Individually the flowers remind one of the pink oleander in shape and colour.

E. Molyneux.

Thunbergia fragrans.—As a rafter plant for a small or medium-sized structure kept at an intermediate temperature this has much to commend it, for its pure white blossoms are borne from the summer often on into the winter. I do not know why it bears the specific name of fragrans, as the blossoms are practically scentless.—W. T.

RED BERRIES AT CHRISTMAS.

Growers who have not the room to grow large holly trees, and yet want some colour in their gardens at Christmas, should grow skimmias. These are ornamental at all seasons. They are compact growing shrubs, and take up but little room, and the beautiful scarlet berries brighten up the shrubbery for several months; indeed, they bloom again while the berries are still on them as the birds rarely trouble them. They are very impartial as to position or soil, and will grow and flourish in any ordinary compost, providing they have depth, which means that the soil should be trenched—or a good-sized hole made, and if the soil is very poor, it would be a pity not to add a little manure, so that the plant may be encouraged to grow away strongly. The skimmias commence to bear berries when in a quite small state. They may also be planted close to the edge of a walk. The best are Skimmia japonica, S. Formanni, S. oblata, and S. ovata; care, however, should be taken that male and female varieties be procured, in which case the berries set with great freedom. Skimmias require but little attention when once well established, and a little mulch of manure in the summer will only be necessary to keep them growing well.

Leonardslee Gardens. W. A. COOK.

PACKING SWEET PEAS FOR EXHIBITION.

The two following papers were read at the Conference arranged by the National Sweet Pea Society on December 8, at the Hotel Windsor, Victoria Street, Westminster:—

Packing Sweet Peas for Exhibition,

(By Mr. THOMAS STEVENSON, of Addlestone.)

The cutting and packing of sweet peas for exhibition is certainly a matter well worth discussing, and an exhibitor would be well advised if he gives it really serious consideration. It is of little use to be able to grow good flowers and not be able to put them up at the exhibition in the best possible condition. Many and varied are the means employed for carrying the flowers to the shows, and one must at least give the exhibitors credit for some pains, especially when we see them using a box that would well hold a good-sized shrub for conveying a dozen bunches of sweet peas in water.

It may be taken for granted that well-grown flowers (by this I mean flowers that have been disbudded and grown liberally) require more care than do their less highly cultivated neighbours; they are rather more easily bruised in packing, and, having more sap in them, are certainly more liable to spot, and all this must be given due consideration, especially when the flowers have to be conveyed a long distance. But if proper precautions are taken as to feeding the plants beforehand, the time of cutting, etc., etc., a few hours' railway journey should have no terrors for the sweet pea exhibitor. I think we should have invited our friend Mr. Cowdy, from Armagh, Ireland, to give his experiences on this matter in place of my own, for anyone who saw his flowers at our exhibition of 1911 must have agreed that they were the acme of perfection, both in freshness and colour, and these should at all times be strong points in favour of any collection. It is not giving away a secret when I tell you that Mr. Cowdy wrote asking me what he should put in the water to preserve the colour of his flowers during transit and I wired back to him, "Use clean, soft water only." Whether he followed my advice I do not know, but certainly he gave us an ocular demonstration of really good colour in sweet peas that had come from a long distance.

When exhibiting near home there should be no question as to when to cut the flowers, because if this can be done on the morning of the show so much the better, and many of the colours will be all the better for it; especially is this the case with the orange, crimson and scarlet varieties, and even some of the pink sorts, for several of these are very apt to take on a touch of magenta after a few hours in water, and there is nothing so depreciating to the pink colour as this tint.

When flowers have to be conveyed some distance then the trouble begins; and yet, if the weather is fine, there is not much to worry about, but if the weather is damp and stormy the problem is fairly difficult, though if a suitable place can be found in which to dry the blooms before packing them, there is still ground for hope that they may emerge from the boxes in a fairly good condition. At all times the flowers should be as dry as possible when they are cut, so I would advise that they be cut either just after the dew has gone off in the morning or left until about four o'clock in the afternoon, when the temperature is generally a little lower. Unfortunately we cannot always choose the exact time to cut, as the length of the railway journey may necessitate cutting in the middle of the day sometimes, or even before they are dry in the morning, and when this latter is the case then the flowers must be treated as though they were cut during rain.

Under any circumstances, if the flowers have to travel some distance they should be cut at least a couple of hours before they need be packed. Immediately they are cut I prefer to place them loosely in water in a fairly light room or shed, where a current of air can pass between them; here, if at all damp, they will soon dry, and, if kept from sunshine, this current of air will not harm them, even if they are dry, but will tend to keep them cool. In a position such as this it is astonishing how much the flowers will grow.

If the weather is wet at the time of cutting some further provision should be made for drying the flowers, such as placing them in a house where a current of air can pass over the hot-water pipes and then among the flowers, or placing them in a dwelling-room where all the windows are open and a good fire is burning. In either case the flowers must be very lightly disposed in vases or jars, but if a little trouble is taken it is surprising how quickly the flowers will dry in this way. I have proved how well this answers, as the flowers have come out fresh and bright after being packed from twelve to fifteen hours.

The age at which flowers should be cut is a debatable point, but if good strong stems and good substance are desired then the flowers must be fairly well matured at the time of cutting, and the top flower must be at least half expanded, though under exceptional conditions, such as a very long rail journey, they may be cut a little younger, but this is not an advantage except, perhaps, from the point of freshness; size, colour, and substance one cannot get in flowers partly opened in water. Here I should like to emphasise the need of a good light place wherein to place the flowers after cutting; if put in a dark room or shed, some of the varieties may partially close up, and if this happens the probability is that they will not expand properly again. After they have been in water for an hour or two in a light room, afterwards packed in dark boxes, there is not that tendency in them to close up.

As mentioned before, the crimson, scarlet, and orange varieties should be left on the plants as late as possible, but some of the pale blue and lavender flowers may improve a little if given an extra hour or two in water, but this must not be overdone or the colour will be fading by the time the judges go round.

The systems of packing are varied, and when visiting the shows one finds many different kinds of boxes and baskets used. In some instances it may be an advantage to carry the flowers in water, but I certainly do not think it necessary, for if the flowers are treated as already advised and given at least two hours in water before packing, they will travel quite well, even if left out of the water for from eight to twelve hours, and I have had them out of water for twenty hours and then they have come up quite fresh after an hour or two in water. But if the flowers are very young and the stems "soft," they certainly will not rise to the occasion, hence my advice to cut rather older flowers, the stems of which are harder.

For packing I use flat hampers in preference to boxes, as they are very light to handle, and the flowers are not liable to sweat and spot in them. I use baskets to hold one dozen fairly good bunches, packed, of course, in one layer only. In really hot weather I use waxed paper for lining the baskets as this prevents too rapid evaporation; if the flowers are in the least damp I prefer very soft tissue paper, and this, I think, absorbs the moisture, which is an advantage.

When packing, especially if the blooms are being sent, instead of being taken, they must be packed tightly enough to prevent any movement in the baskets or boxes, or bruised flowers will be the result.

If the few precautions that I have outlined are followed, the flowers ought certainly to arrive at the exhibition in fair condition, and it only remains for them to be put in water as quickly as possible after arrival and set out temporarily in the various positions allotted to the classes, first cutting any ties that may be around them. Here they will freshen up and grow, and the work of arranging the flowers may be carried out in a leisurely manner without any need for worry lest some are spoiling while the others are being arranged.

Packing Sweet Peas for Market.

(By THOMAS PAGE, of Hampton.)

There is not much to be said concerning methods of packing sweet peas for market. To insure that the blooms arrive at their destination in a good and sound condition the most important detail is that they must be of the first quality culturally, and not at all moist when being packed. It is also most essential that directly the flowers are cut the bunches should be placed, not too thickly, in water, taking care not to wet any of the blooms, otherwise they may possibly heat in transit, the stems alone being in the water.

I find that 24-sized pots, with the hole cemented up, serve very well for holding the newly-cut flowers; in each pot we put ten or twelve bunches, according to size. If the weather be hot and moist it is as well to take the bunches out of the water and place them in empty pots for about half an hour, to allow them to drain, previous to packing.

The mode of packing I consider the best adapted for the conveyance of sweet peas to market is as follows, viz., a flat box about 5in. deep, 20in. long, and 12in. wide, line with blue or tissue paper, and pack in each box 30 to 36 bunches, placing a piece of tissue paper between each row of bunches. Packed in boxes of this character the contents have not room enough to move about and consequently damage is prevented. If, however, I have to send sweet peas any considerable distance, and the weather be hot and dry, I find it a good plan to put a small piece of wet cotton wool round the base of the stems just before packing. The varieties I consider most suitable for packing and travelling are Mrs. Hugh Dickson, Mrs. Routzahn Spencer, Countess Spencer, Nora Unwin, King Edward Spencer, Sunproof Crimson, Asta Ohn, and Florence Nightingale. These are all good market varieties.

Tecoma Smithi.—It is only when plants of this tecoma are well baked in the summer's sun that they flower in a satisfactory manner in a small state. In this condition it forms a bright and attractive winter feature in the greenhouse. The flowers, which are broadly tubular in shape, are borne in clusters. They are of a rich yellow colour, tinged outside with deep orange.—W. T.

RED BERRIES AT CHRISTMAS.

Growers who have not the room to grow large holly trees, and yet want some colour in their gardens at Christmas, should grow skimmias. These are ornamental at all seasons. They are compact growing shrubs, and take up but little room, and the beautiful scarlet berries brighten up the shrubbery for several months; indeed, they bloom again while the berries are still on them as the birds rarely trouble them. They are very impartial as to position or soil, and will grow and flourish in any ordinary compost, providing they have depth, which means that the soil should be trenched—or a good-sized hole made, and if the soil is very poor, it would be a pity not to add a little manure, so that the plant may be encouraged to grow away strongly. The skimmias commence to bear berries when in a quite small state. They may also be planted close to the edge of a walk. The best are Skimmia japonica, S. Formanni, S. oblata, and S. ovata; care, however, should be taken that male and female varieties be procured, in which case the berries set with great freedom. Skimmias require but little attention when once well established, and a little mulch of manure in the summer will only be necessary to keep them growing well.

Leonardslee Gardens. W. A. Cook.

PACKING SWEET PEAS FOR EXHIBITION.

The two following papers were read at the Conference arranged by the National Sweet Pea Society on December 8, at the Hotel Windsor, Victoria Street, Westminster:—

Packing Sweet Peas for Exhibition,

(By Mr. THOMAS STEVENSON, of Addlestone.)

The cutting and packing of sweet peas for exhibition is certainly a matter well worth discussing, and an exhibitor would be well advised if he gives it really serious consideration. It is of little use to be able to grow good flowers and not be able to put them up at the exhibition in the best possible condition. Many and varied are the means employed for carrying the flowers to the shows, and one must at least give the exhibitors credit for some pains, especially when we see them using a box that would well hold a good-sized shrub for conveying a dozen bunches of sweet peas in water.

It may be taken for granted that well-grown flowers (by this I mean flowers that have been disbudded and grown liberally) require more care than do their less highly cultivated neighbours; they are rather more easily bruised in packing, and, having more sap in them, are certainly more liable to spot, and all this must be given due consideration, especially when the flowers have to be conveyed a long distance. But if proper precautions are taken as to feeding the plants beforehand, the time of cutting, etc., etc., a few hours' railway journey should have no terrors for the sweet pea exhibitor. I think we should have invited our friend Mr. Cowdy, from Armagh, Ireland, to give his experiences on this matter in place of my own, for anyone who saw his flowers at our exhibition of 1911 must have agreed that they were the acme of perfection, both in freshness and colour, and these should at all times be strong points in favour of any collection. It is not giving away a secret when I tell you that Mr. Cowdy wrote asking me what he should put in the water to preserve the colour of his flowers during transit, and I wired back to him, "Use clean, soft water only." Whether he followed my advice I do not know, but certainly he gave us an ocular demonstration of really good colour in sweet peas that had come from a long distance.

When exhibiting near home there should be no question as to when to cut the flowers, because if this can be done on the morning of the show so much the better, and many of the colours will be all the better for it; especially is this the case with the orange, crimson and scarlet varieties, and even some of the pink sorts, for several of these are very apt to take on a touch of magenta after a few hours in water, and there is nothing so depreciating to the pink colour as this tint.

When flowers have to be conveyed some distance then the trouble begins; and yet, if the weather is fine, there is not much to worry about, but if the weather is damp and stormy the problem is fairly difficult, though if a suitable place can be found in which to dry the blooms before packing them, there is still ground for hope that they may emerge from the boxes in a fairly good condition. At all times the flowers should be as dry as possible when they are cut, so I would advise that they be cut either just after the dew has gone off in the morning or left until about four o'clock in the afternoon, when the temperature is generally a little lower. Unfortunately we cannot always choose the exact time to cut, as the length of the railway journey may necessitate cutting in the middle of the day sometimes, or even before they are dry in the morning, and when this latter is the case then the flowers must be treated as though they were cut during rain.

Under any circumstances, if the flowers have to travel some distance they should be cut at least a couple of hours before they need be packed. Immediately they are cut I prefer to place them loosely in water in a fairly light room or shed, where a current of air can pass between them; here, if at all damp, they will soon dry, and, if kept from sunshine, this current of air will not harm them, even if they are dry, but will tend to keep them cool. In a position such as this it is astonishing how much the flowers will grow.

If the weather is wet at the time of cutting some further provision should be made for drying the flowers, such as placing them in a house where a current of air can pass over the hot-water pipes and then among the flowers, or placing them in a dwelling-room where all the windows are open and a good fire is burning. Packing Sweet Peas for Market.

(By THOMAS PAGE, of Hampton.)

There is not much to be said concerning methods of packing sweet peas for market. To insure that the blooms arrive at their destination in a good and sound condition the most important detail is that they must be of the first quality culturally, and not at all moist when being packed. It is also most essential that directly the flowers are cut the bunches should be placed, not too thickly, in water, taking care not to wet any of the blooms, otherwise they may possibly heat in transit, the stems alone being in the water.

I find that 24-sized pots, with the hole cemented up, serve very well for holding the newly-cut flowers; in each pot we put ten or twelve bunches, according to size. If the weather be hot and moist it is as well to take the bunches out of the water and place them in empty pots for about half an hour, to allow them to drain, previous to packing.

The mode of packing I consider the best adapted for the conveyance of sweet peas to market is as follows, viz., a flat box about 5in. deep, 20in. long, and 12in. wide, line with blue or tissue paper, and pack in each box 30 to 36 bunches, placing a piece of tissue paper between each row of bunches. Packed in boxes of this character the contents have not room enough to move about and consequently damage is prevented. If, however, I have to send sweet peas any considerable distance, and the weather be hot and dry, I find it a good plan to put a small piece of wet cotton wool round the base of the stems just before packing. The varieties I consider most suitable for packing and travelling are Mrs. Hugh Dickson, Mrs. Routzahn Spencer, Countess Spencer, Nora Unwin, King Edward Spencer, Sunproof Crimson, Asta Ohn, and Florence Nightingale. These are all good market varieties.

Tecoma Smithi.—It is only when plants of this tecoma are well baked in the summer's sun that they flower in a satisfactory manner in a small state. In this condition it forms a bright and attractive winter feature in the greenhouse. The flowers, which are broadly tubular in shape, are borne in clusters. They are of a rich yellow colour, tinged outside with deep orange.—W. T.

NATURALLY GROWN CHRYSANTHEMUMS.

The cultivation of bush or decorative chrysanthemums is a subject with which everyone is more or less well acquainted, and many systems are adopted to ensure success, but it is very doubtful if even a small percentage of growers allow the plants absolute freedom throughout the whole period of growth. In my early days of chrysanthemum growing it was quite the practice for cut flower purposes to stop the plants as often as possible up to about the middle of June, this being about the time of shifting into the pots in which they were flowered. The plants at this stage would be about nine to fifteen inches high, and immediately after potting the pots were plunged to about three or four parts of their depth in ashes. Needless to say, they soon began to grow away freely, and the shoots being crowded, they soon attained a good height, and, if anything, remained rather on the soft side. If I remember rightly they required much attention in respect to tying, staking, etc. With the exception, perhaps, of plunging the pots, this is the most general method adopted to-day for the cultivation of the decorative and single chrysanthemums, and in most instances it probably answers very well.

Some seasons ago I was not at all satisfied with the results obtained in this way, and decided to try something different. I tried a few varieties grown quite naturally, and the results being far and away better than from the stopped plants I at once adopted this method for growing all my decorative and single varieties.

Where stopping is practised with a definite object in view, say to induce the plants to bloom at a certain time, or to keep certain varieties very dwarf, then I have nothing to say against it; but when it is only done for the purpose of obtaining a multiplicity of half-ripened shoots, then I submit that it is not desirable. It is certainly not conducive to the production of either better or more bushy plants or higher quality in the bloom. For market purposes where the plants are restricted to six or eight shoots, and are required to produce what might be termed half specimen blooms, then I believe it is an advantage to take out the point of the shoot just before it makes first natural break; in this way fewer shoots are made, and they are somewhat stronger and possibly a little more regular. Where, however, a big crop of moderate-sized flowers, with stiff stems is required, the following system of culture will, I am sure, give satisfactory results. In very few instances will the plants be taller than those grown on what may be termed a stopping system.

Cuttings may be rooted any time between January and the middle of March either in thumbs, small or large sixties, or in boxes, and if large quantities are required pricked out on the stages or bed in a cool house. Cuttings of late varieties ought to be rooted fairly early to ensure a good season's growth, as it is generally acknowledged that these require a little more care to produce a really good crop than do some of the earlier varieties. The usual procedure of potting off into large sixties must be carried out before the young plants are in a way drawn, transferring them to a cold frame at once. Here, as soon as rooting commences, they must be kept just as hard as possible without letting them sustain a check by being frozen or cut about by cold northerly or easterly winds.

Before they become pot-bound they should be shifted into forty-eights, potting firmly and giving them plenty of room to ensure stout short growths. As soon as rooted nicely in the last-mentioned size of pot, if favourable weather conditions prevail, they may be transferred to the open from the frames. If they have been treated as suggested, one or two degrees of frost will not do them any harm. If plenty of frame-room is at liberty they might with advantage be left there till the first week in May. It is not necessary, and I frequently, through lack of frame room, put mine out quite by the middle of April.

The final potting should be done as soon as the plants have filled their pots with roots, which probably will be about the middle of May, using 9in. pots and a fairly holding compost, with just a small amount of well-rotted manure added, and a little bone-meal and soot. Other manures are not necessary for some time, the whole object being to keep the plant growing sturdily, and if they can be kept in this condition they will produce from twelve to thirty shoots, or even more, at the first natural break. After potting stand them two or three feet apart on a bed of ashes or a hard surface, and secure the stakes to a horizontal wire to prevent their being blown about by the wind.

The plants are not staked till they are put in their permanent positions, and then only one is used to each, giving the growths perhaps a couple of ties at the time of staking. After this they are left to themselves till well on in August when the shoots are from a foot to eighteen inches in length, and in some instances more. Each shoot is slung to the central stake and in many instances they are not tied again after this, although all the plants receive attention a week or two previous to housing and tied when necessary.

Watering is carefully done throughout the season, and I seldom find it necessary to use much manure before August, when the plants are given a top-dressing of soil, and of course a watering once or twice a week with liquid manure.

If spray bloom is required they are allowed to flower in an absolutely natural manner, but if single flowers are required then one bud is retained to each shoot, and the rest rubbed out, and if this is done the flowers are about the right size to exhibit as decorative chrysanthemums. If they are singles the flowers come large enough for any purpose, and according to the variety vary from four to seven inches in diameter, and the plants are certainly more shapely and the flowers better disposed on them than is usually the case with bush plants that have been stopped.

CHRYSANTHEMUM MRS. HUBERT WILLIAMS.
A beautiful single variety, the blooms bright pink.

From the time the bud appears they are

systematically fed with a little artificial fertiliser every week or ten days, and the very late varieties are not neglected after the feeding of the early and mid-season varieties are discontinued. In fact, they are fed liberally, and at the time of writing (December 13),such varieties as J. W. Crossby, Winter Cheer, Thompson, and one or two others are having weekly feeding; the first-named is showing colour, while Winter Cheer and Thompson will be at their best about the first week in January. Varieties that are very fine now under this treatment are A. J. Balfour, Maud Jefferies, White and Yellow Victoria, Kathleen May, True Gold, December Gold (this latter just going over), Brightness (single), Mrs. Hubert Williams (single; this latter having been good since early in November), Jack (single), Allman's Yellow, and Hetty Wells. By this it will be seen that when grown quite naturally they flower at just about the same dates, and it is quite easy by making a judicious selection of varieties, to maintain a succession of bloom without any difficulty from early in October to the end of January, and this is what I endeavour to do. I have had J. W. Crossby and Winter Cheer quite good until the first week in March in some seasons. The style of the plants will be readily seen from the two illustrations given herewith.

Thomas Stevenson.

CHRYSANTHEMUM MERSTHAM JEWEL.

An effective single variety; the blooms terra-cotta red, with golden disc and yellow points to the florets.

TREES AND SHRUBS WITH ORNAMENTAL FRUITS.

With an abnormal summer such as we passed through this year, Nature expresses her redundance in a variety of ways, and in no direction more so than in the quantity and colour of the fruits produced by various trees and shrubs. Even the most casual observer cannot have failed to notice the rich colour of fruit produced in orchard and fruit garden, and also of the fruits of many of the occupants of the pleasure ground.

Nowhere in the garden has the abundance of fruit been more apparent than among trees and shrubs of an ornamental character. Consequently, where a representative collection is grown, the fullness of the year attained a high degree of beauty, and the fruits, in conjunction with the autumn tints of the leaves, imparted to the garden a series of most delightful colour effects.

It is not generally the custom to regard in planting trees and shrubs from the standpoint of the ornamental aspects of their fruits in the autumn. Probably one of the shrubs that has for the longest period been employed for this purpose, and now one of the commonest, is Cratægus pyracantha, of which the form Lelandi is the best. This fine old shrub is one of the most reliable, and the specimens, as seen at present, on cottage walls and elsewhere, loaded with bright orange fruits, give to it a first place among the best of fruiting shrubs. The thorns are conspicuous in autumn as, for example, Cratægus Crus-Galli, Carrieri, orientalis, and tanacetifolia are all large fruiting kinds, and of the two latter, we have here mature trees that are loaded with high-coloured cherry-like fruits, the latter standing out prominently from the grey-green of the foliage.

The symphoricarpuses or Snowberries yield fruits of most distinct appearance, S. racemosus and S. occidentalis being reliable kinds in this respect. They are best massed in quantity, then it is that one fully realises their great beauty when in fruit, the snow-white fruits, like huge pearl-drops, convey at some distance the same effect as earlier in the year is produced by the dwarf Philadelphus when in flower.

Of older fruiting shrubs in full bearing now, are Arbutus Unedo, with pendulous, ball-like fruits in clusters, that later change to a reddish hue and present a charming picture at the same season as the flowers expand. Citrus trifoliata (the hardy orange) is worthy of mention for its curious growth and orange-like fruits, so also is Celastrus scandens, a plant producing orange fruits and that succeeds equally well as a wall shrub or ascending another tree.

The majority of berberis are free fruiting shrubs, although not always conspicuous; in this respect Berberis Wilsonæ, in itself a pretty, densely branched, spiny shrub of recent introduction, is a notable addition, the fruits being a bright and attractive shade of coral red. Pernettyas and skimmias are best in masses, the latter, on account of the sexes, ensures fertilisation and subsequent fruit production; while the former admits of the full play of contrast with the diverse colours of the fruits. The beauty of rose-hips as decorative elements is of a high order in the autumn. Rosa rugosa is a well-known type, and a notable addition to this family is found in Rosa Moyesi, the hips resemble in shape an oriental water-bottle, and are coloured glowing orange-red.

Cotoneaster applanata, recently introduced, bears an abundant crop of bright scarlet berries that contrast admirably with the dark-green foliage, while the fruits are retained into the winter season.

Two new shrubs of merit in this respect are Rubus innominatus and Viburnum rhytidophyllum, the former a member of the raspberry or bramble family, producing its fruits in compound heads and of a vivid orange hue, the viburnum having elongated fruits, which are carried in dense clusters, and are a rich shade of crimson.

No selection of decorative fruiting shrubs would be complete unless it includes the various forms of crab, of which the variety John Downie is the most brilliant in colour; so, too, recognition should be given the species and varieties of Ilex (holly), as they are among the most beautiful of fruiting evergreens, Ilex flavescens, with yellow berries, being a striking object when in fruit. Of ornamental vines, Vitis vinifera purpurea has carried excellent fruit this season in the open, and in Vitis heterophylla humulifolia we have a colour almost unique in fruits; in this plant the berries are an enchanting shade of turquoise blue.

Thomas Smith.

Coombe Court Gardens.

An edition of "SWEET PEAS AND THEIR CULTIVATION," by C. H. Curtis, has just been issued for 1912, and consequently this is the most up-to-date work on the subject. The price, by post, is 1s. 2d. (cloth, 1s. 9d.) from the Publishers, 148-9, Aldersgate Street, London, E.C.

TREE IVIES.

The peculiarity of the ivy in altering its character from a trailer or climber to a shrub of bushy habit on attaining maturity has been put to good use by horticulturists, for by propagating from the mature growths a very useful group of evergreen shrubs has been obtained. Not only do the commoner kinds, which alter their habit when the flowering age arrives, but the many varieties which differ from the type in the colour, size, or shape of the foliage do so also; therefore the range of bush varieties is almost as large, if not larger, than that of the trailing kinds. Quite as much difference may be noticed in the shape of leaf between the juvenile and mature form as in the habit, and the percentage of some bush forms would be difficult to give with any degree of accuracy.

It is not possible to raise bush forms from seeds, for seeds sown from any of the varieties produce trailing forms. Bush varieties, though usually retaining the stiff, shrubby habit, sometimes revert to the trailing types, though this may be checked by the removal of shoots which develop the tendency. It is not difficult to raise bush forms from some trailing kinds, for if a trailing kind is planted against a support which it can quickly cover, it straightway commences to form flowering branches. Thus, a trailing variety planted against a pillar or over an old tree-butt, may, in the course of a few years, entirely alter its habit, and it is no uncommon thing to find two entirely different kinds of growth from the same plant, that about the lower parts corresponding with the juvenile form with leaves typical of that stage, and the higher shoots agreeing in habit and foliage with some tree variety. The juvenile habit may, however, be prolonged indefinitely by keeping its growth restricted. This may be seen in the case of common Irish ivy growing on walls where it is hard clipped each year. In such cases no bushy branches are to be seen, but where clipping has been neglected for two or three years flowering branches are soon formed.

By repeatedly propagating from trailing kinds it is possible to keep them true to type for many generations. Increase of the tree forms is usually by cuttings, or by grafting on to stocks of the trailing Irish ivy. The latter is the quicker method of producing serviceable plants, for those raised from cuttings grow very slowly for several years.

The decorative value of the various kinds of tree ivies has been demonstrated on several occasions at the Horticultural Hall, and in this way their value for the decoration of large halls in winter may be estimated; they are, however, even better suited for outdoor use, and in some gardens series of beds are planted with gold, silver, and green kinds for the sake of colour effects. For grouping in beds, the weaker growers are better adapted than for growing as isolated plants, though, as specimen bushes, the larger and stronger kinds are admirably suited.

The accompanying illustration of a bush of the tree form of Irish ivy (Hedera Helix var. canariensis), growing in the Royal Gardens, Kew, is evidence of the ornamental character of this variety, although the beauty of the glossy leaves cannot be reproduced. Similar plants may be grown of a number of kinds, such as the mature forms of the large-leaved H. dentata, H. algeriensis, H. macrodonta, H. maderiensis, H. gigantea, and H. amurensis. Several of these fruit freely and are additionally attractive when covered with deep purple, black, or yellow fruits as the case may be.

Among smaller-growing kinds we have the numerous golden-leaved varieties, such as H. arborescens folius aureis, H. aurea, H. Golden Cloud, H. palmata aurea, H. spectabilis, and H. flavescens. Silver sorts are represented by H. Silver Queen, H. maderiensis variegata, H. arborescens folius argenteis variegatis, H. Crippsi arborescens, and H. La Reine. Varieties with green or bronze leaves are H. dentata, H. Emerald Green, H. purpurea, H. rhomboidea, and H. minima. Several of these varieties form compact bushes 3 to 4ft. high, and some grow even taller.

Any ordinary garden soil suits the ivies and they give little trouble beyond an occasional cutting over. This is best done in spring, for at that time the remains of the inflorescences can be removed and new growth quickly appears to cover up the cut ends of the branches.

A SPECIMEN OF THE TREE FORM OF THE IRISH IVY AT KEW.
(Hedera Helix canariensis arborescens.)

CIDER APPLES.

I can assure my friend, Mr. E. Molyneux, who contributed a short article under the above heading in the issue for December 2, that he is right in the conclusion he has arrived at, i.e., that there is much more art required in producing good cider than is generally thought. I would further add that, not only does the right kind of apple play an important part in the production of the best cider, but there are comparatively few varieties that are suitable for making cider by themselves, and therefore one of the secrets of cider making is to know how to blend your apples which possess different characteristics in order to produce a wholesome and palatable beverage.

In the varieties which Mr. Molyneux noted at the Brewery Exhibition, he appears to have got a little astray, probably owing to careless or illigible labelling, as regards the names. "Sweet Harcourt" should, I think, be "Sweet Harcombe"; "Jarligton Mill" should read "Yarlington Mill, which is a well-known Somerset apple; "Cup and Liberty" should be Cap of Liberty; "Hay Masters" is Harry Masters; and "Comane Red" should read Cowarne Red, this being a favourite old cider apple with makers in Gloucestershire.

Many of the cider apples are of local origin, and were raised in the first place from pips thrown out with the pulp from the cider mill after it had gone through the press. Many of the quaint names given to cider apples are of local origin, the varieties either being named after the persons who introduced them or the places where they were raised. In the orchards of the West Country there are hundreds of local varieties of cider apples, some of which are quite unknown outside the districts where they are grown, while others, such as Kingston Black and Foxwhelp, are known more or less throughout the western counties.

If Mr. Molyneux would like further information about cider apples, he should apply to the Director of the National Fruit and Cider Institute, at Long Ashton, Bristol, as this institution has done a great deal during the past few years in collecting, classifying, and testing local cider apples.

Mr. Molyneux is forced to the conclusion that cider apple trees are not much in demand, and that there does not appear to have been much planting done in recent years. This, unfortunately, is true; and cider apples have doubtless been neglected for the sake of table varieties; but a change is now taking place, and within the past three years hundreds of trees propagated at the National Fruit and Cider Institute have been distributed and planted in orchards in the counties that contribute to the upkeep of the establishment. As a matter of fact, people in the West of England are realising the necessity of planting more cider apples. Unless this is done the present promising outlook for the cider industry must end in disappointment in the future if the fruit for grinding purposes is not forthcoming.

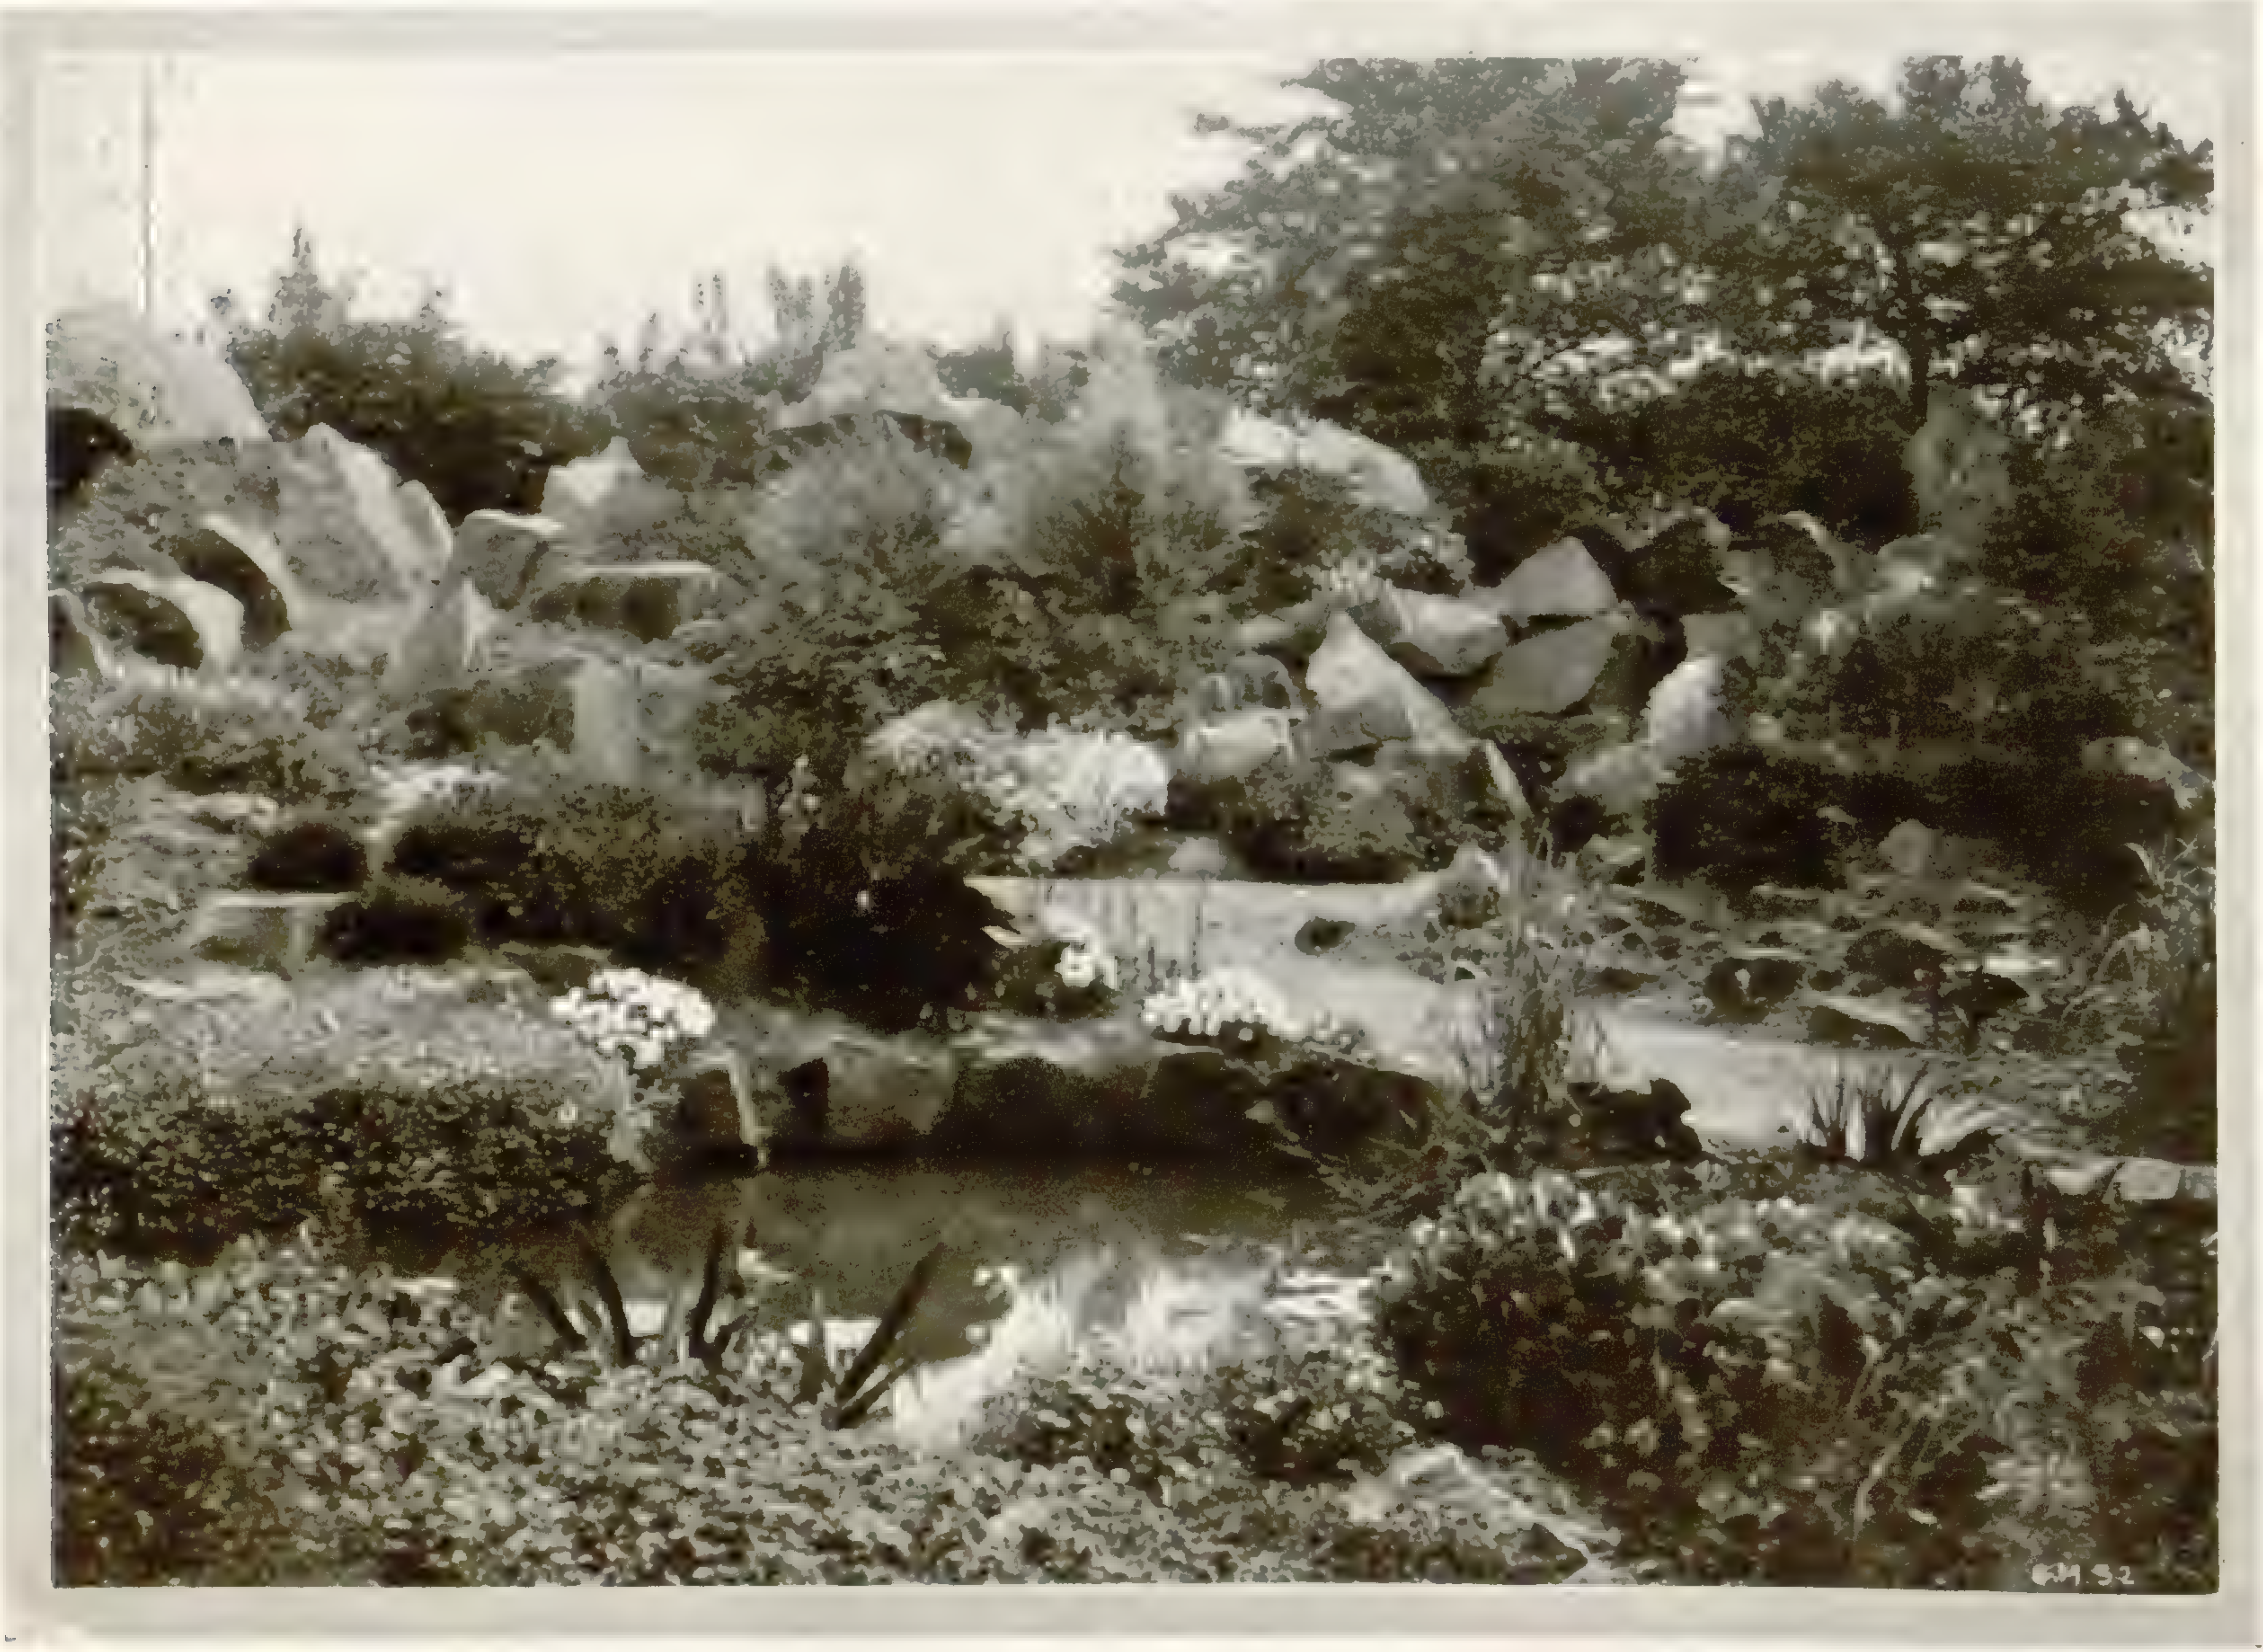
Throughout this year there has been a great demand for cider; prices have been good, and makers are now busy filling up their empty hogsheads. Only the other day a large cider maker informed me that he never remembered paying so much for apples for grinding, and the fruit of several choice cider varieties has this year fetched more money than table apples. These facts appear to support the contention that the shortage of good cider apples is beginning to be felt, owing to the death of old trees, and lack of new ones to take their places; and it is hoped that the present generation will realise its responsibility in respect of cider fruit, and not only fill up old orchards, but continue to plant new ones.

G. H. Hollingworth.

WHERE ROCK AND WATER MEET.

The history of horticulture is one of changing ideas. In all its changes it is the "novel" idea that attracts. The way of progress lies through new ideas and rising art, and progress uses present successes as stepping stones to the something better beyond.

Garden life and garden art are so full of possibilities that one can only write with certainty of past and present things, as the future is ever-widening to a greater conception of the garden beautiful, and though the forward spirits of the present generation are helping to mould the future ideals, yet the ultimate result is beyond our ken.



A CHARMING VIEW IN AN EAST ANGLIAN ROCK GARDEN.

But to return to the present-day garden —for this is the mark by which the present-day garden lovers are judged; it is well for us that the natural ideal in gardening has had such full play, and that we have brought the countryside into the garden, and have given to so many subjects that unrestrained freedom which is at once the grace and charm of the floral world.

The subject of these opening-out thoughts is connected with the value of rocks and water in the making of garden scenes. The use of rock has given to us the whole range of mountain flora. Thousands of small plants, many of them of supreme beauty, and all of them of entrancing interest, have thus been brought within the confines of our English gardens. This in itself has been of two-fold benefit, i.e., by the formation of gardens practically suited for the culture of these plants and for scenic effect, and the increased knowledge gained by the study of the numerous flower groups and their varieties.

Then there is the great development of water gardening, with its attendant host of aquatic, sub-aquatic, and moisture-loving plants. From the lake to the lily pool, from the streamlet to the bog, we gain not only the never-failing charm of water scenery, but the full beauty of the wealth of plants which are inseparably associated with pools and water margins. In the accompanying illustration of a portion of the rock garden at Holland House, Southcliff, we obtain just a small idea of the value of water in conjunction with rocks, and this where space is somewhat restricted. The idea of utilising rock and water for decorative effect is not new. So many English gardens can now glory in this ideal combination, and the Japanese artists of the distant past worked with the same combination.

Provided the work is not over-elaborated or, on the other hand, made paltry for the want of material, or want of discretion on the part of the designer, the rock and water scenery will provide the most charming aspects of garden beauty. The prime necessity is to work for undulating ground, and allow the waterways to fall naturally through the lower levels. Water may be in the form of a large lake suitably outlined and planted; it may be a series of winding pools, alive with beauty at the margins; or possibly a well-planted streamlet. The main thing, the water, is secured in any case, and once this is done one can work to that, creating and shaping mounds, slopes, banks, foregrounds, and backgrounds, with the one dominant idea of making a happy combination which shall breathe interest, charm, and artistic effort at every point.

The placing of rocks, and their conformation will be a matter of individual study and individual requirements. Bold bluffs, and cliff-like formations, are only desirable where one has space enough to emphasise the bold character pictured, and water enough to take off the hardness delineated by the free use of massive rocks. In this case, assuming that a perpetual water supply is assured, the rocks should, at places, rise sheer out of the water itself, thus losing the lower lines of the stone, and gaining some fine spaces between the individual rocks for the naturalisation of dwarf plants, and, furthermore, ensuring those exquisite "reflections" which are obtainable only by the mirroring of flower and foliage in clear water.

On the other hand, for a small garden some very pretty effects can be obtained by a restricted use of stone, and in the utilisation of gently sloping banks, and low mounds, which can be planted with trees, shrubs, as well as with a multitude of other plants. The free use of these subjects will result in the formation of undulating scenery in which the pools or stream will form the key of the picture. In this case the rocks that are used will be shown as outcrops from the soil banks, and this will almost entirely free the water margins for the planting of waterside subjects. The wonderful foliage masses formed by waterside plants will effectually hide any bare outlines, and give almost a tropical luxuriance of vegetation. Gunneras, Rodgersias, irises, astilbes, spiræas, juncas, scirpus, eulalias, glyceris, lobelias, lythrums, and a host of other strong growing waterside subjects, are really glorious during the whole of summer, giving their varying colourings, heights, and beauty to the waterside garden.

While not wishing to dwell too much upon the subject, I desire to promote a further enthusiasm for the many diverse pictures of garden beauty that may be created by varying arrangements of rock and water. The broad flagged pathway which winds by the tall waterside irises; the stepping stones placed in shallow waters, where calthas, mimulus, myosotis, villarsias, and many other subjects grow in gay profusion; the ridges of rock placed so as to catch the movement of the wind-stirred rippling waters, or the grim boulder rising out of the deep pools, are all charming combination of rock and water.

Or, going further still, consider a garden in the Japanese style, where every stone, every conformation of the landscape, every phase of water scenery has its own intense interest and meaning, and where stone is used freely as the highest essential of Japanese garden art. Study the outline of those quaint stone bridges or those granite slabs, which carry the visitor on an informal pathway across the water. Study those quaint stone well heads, and those more quaint stone lanterns. Note these things, and consider if we have yet reached the zenith of horticultural art. There is more in garden art than we have yet considered; more in the use of rocks and running water, in the draping of crags, and in the embellishment of pools than we have ever dreamed.

At the meeting of rock and water we now stand, and the way is open for the landscape gardener to make a fuller and freer use of these agents than he has done in the past. P. S. Hayward.

Erlangea tomentosa.—It is not many years since this erlangea was introduced from Central Africa, but it has already become generally distributed. This is, to a great extent, owing to its ready propagation and easy culture, for cuttings may, in the spring, be struck without any trouble, and the plants so obtained will make good flowering examples by the autumn. It cannot be regarded as showy; indeed, it bears a general resemblance to a eupatorium, but the undersides of the leaves and the young shoots are clothed with a whitish tomentum. The ageratumlike blossoms are of a lavender shade with a lighter centre.—W. T.

SPECIMEN HYDRANGEAS.
Arranged in the Portico of the Mansion, Buxted Park.

HYDRANGEAS.

Some years ago large specimens of these shrubs were usually seen at most of our summer and autumn shows, amongst collections of stove and greenhouse plants, but in time they became so common that judges passed them over in favour of specimens of more choice and rare subjects, hence the reason they lost favour. Small plants carrying one truss of bloom are grown by the thousands for market, and usually meet with a ready sale at a few pence each. No plant is more easily grown than the hydrangea, and few will put up with such rough treatment.

To produce plants having a truss of bloom on a single stem, prepare a bed in a cold frame about the middle of August, the soil must be of a rich, light, sandy nature, about four inches deep. Choose cuttings of the young shoots having plump terminal buds. If dwarf plants are desired, the cuttings should not be more than four or five inches long. Remove the lower pair of leaves, but take care not to injure the buds at their base, as the shoots from these will help to form large specimens later on if desired. The cuttings should be inserted up to the first pair of leaves, allowing a distance of about three inches each way between them, taking care to make each cutting firm in the soil; about three hundred and fifty cuttings may be inserted in a one-light frame six feet by four. When all the cuttings have been inserted, put on the light and shade from the sun, sprinkle with water every evening until rooted, when the light should be removed to harden the young plants. By November they will have shed their leaves, and should be well rooted, having stems from three to four inches long, with a plump bud on the top.

Potting should now be resorted to, the strongest and best rooted should be put straight away into 48's, the smaller ones into large 60's. When potted they should be returned to the frame and protected from rains by having the lights put over them, and in frosty weather afforded a protection to prevent their being frozen. Early in February a batch of the most forward may be taken into a structure in which a moderate temperature is maintained, but growth must not be unduly excited, or the plants will fail to bloom satisfactorily. I have had plants in full bloom as early as the first week in March, from twelve to fifteen inches in height, with heads as far through grown in 48's from cuttings inserted in a cold frame in August. Where a quantity of these have to be provided this is the most simple and economical way of producing them that I am acquainted with.

If young plants of this description are well attended to in the way of watering when in bloom they will make a couple of small shoots at each pair of leaves, in addition to a couple from the eyes beneath the surface of the soil. When the flowers have faded, the trusses should be removed, and these young shoots encouraged to grow. If shifted into nine-inch pots by the autumn they will make fair-sized plants, and if half a dozen or more are arranged in a large pot or tub you have a specimen the second year. In three years from the time the cuttings are taken specimens may be had from four to five feet through them and as many high.

To induce these large specimens to bloom freely the points of the young shoots ought not to be allowed to suffer from the early autumn frosts. If they are removed to an open shed where the leaves can be kept free from damp, they will gradually ripen and fall off while in this position. The plants need but little water at the roots, only just enough to keep the buds plump being sufficient. We have often wintered large specimens by just turning the pots on their sides in sheltered places, covering them with litter, but we prefer a dry shed or outhouse where the buds can be exposed during favourable weather, as they are not then so liable to damp off.

In some parts of the country where the winters are mild hydrangeas may be allowed to remain out without protection, but such do not often bloom so freely as those whose buds have not been injured by the damp and frost. Large specimens when planted out should always have some protection unless in a favourably situated place. There are not many species of hydrangeas sufficiently hardy to withstand the rigour of our winters with impunity, but I have never known H. paniculata grandiflora suffer in the least from the most intense cold of our winters, but this belongs to a class quite different to that which includes the Japanese kinds. The flowers of the latter are produced on the terminals of the preceding year's shoots, whereas those of paniculata are found on those of the current year. The three kinds usually found growing in our gardens, and regarded with the most favour by the market growers are Hortensis, Otaksa, and Thomas Hogg. There are several others, such as quercifolia stellata, japonica, and japonica variegata, but the three first-named are those most commonly met with. Hortensis and Otakso can both have the colour of their flowers changed to blue by adding sulphate of iron to the water. In some places where this abounds in the soil there is no need to add the same.

APPLE ANNIE ELIZABETH.

A large and handsome culinary variety of excellent quality; the fruits illustrated were grown by Mr. J. Whittle, gardener to Colonel Borton, Cheveney, Kent.

We have known plants having blue flowers sold by hawkers as new species, but which have proved to be nothing more than the common forms treated with these chemicals. There are no blue hydrangeas naturally, and some species fail to respond to the treatment suggested. I have not known Thomas Hogg turn blue, but have seen the flowers a dull pink. To grow this kind to perfection it should have a very rich light soil; its habit is very slender, therefore should be grown in an open sunny position. I have planted this in tubs with hortensis, and while the latter has turned a most beautiful blue, Thomas Hogg has not altered its colour in the slightest degree. Quercifolia is most attractive when well grown, its foliage differing from the other kinds, while the trusses of stellata have a light graceful appearance. Two kinds of recent introduction are Narcissi and Veitchi, both of which promise to become popular, but as yet they are but little known to the general body of growers.

H. C. Prinsep.

GREENHOUSE JASMINES.

The various species of jasminum are characterised by the refined and delicious fragrance of their flowers, and it may be said that the common and hardy form, known as J. officinalis, is unsurpassed, and perhaps unequalled in this respect. In addition to the hardy species there are a number which require either stove or greenhouse treatment, and several of these are well worth cultivating.

From India we have J. grandiflorum, which bears in profusion large white flowers, and, further, is found to luxuriate in the cool greenhouse. The same applies to J. heterophyllum from Nepaul, and J. odoratissimum, which hails from lovely Madeira. Borneo supplies us with J. gracillimum, whose fine white flowers are produced in uninterrupted succession over many months in the year; together with a double-flowered species in J. Sambac flore pleno, and the fine J. Duchesse d'Orleans, it requires a warm house in order to bring out its full capabilities and to do it justice. J. gracilis, too, is usually treated as a stove plant, but experiments have gone to prove that it succeeds admirably in an ordinary greenhouse. It is of slender growth, and care must be taken not to overpot it in the early stages of its growth.

Each and all of the jasmines thrive in loamy soil, enriched with short manure, and rendered porous with sand, while their propagation is of a very simple order, being effected by means of cuttings inserted in pots at any season of the year. Kept close in a propagating case they form independent plants in a very short time, and it may be suggested that where accommodation exists, they be planted out and utilised to furnish the roof, pillars, or ends of both stove and greenhouse.

Walter H. Aggett.

APPLE ANNIE ELIZABETH.

This is a grand old apple, and one that holds its own in good competition, and finds a fitting place in many gardens. It is a culinary variety of great merit, and its large, roundish, ribbed fruits are very fine either for baking or other culinary purposes, while late in the season they are not bad eating in a raw state. There is a briskness and sprightliness about the flower of Annie Elizabeth that commend it to many tastes. The skin is yellow with crimson spots and streaks, and the flesh is firm and white. It may not be generally known that Annie Elizabeth was raised by Messrs. Harrison and Sons, of Leicester, and was granted a First Class Certificate by the Royal Horticultural Society in 1868—well on towards half a century ago. The dish of fruits illustrated in the present issue was one of the splendid set exhibited at the Great Fruit Show this autumn by Mr. J. Whittle, gardener to Colonel Bourton, Cheveney, Hunton, Maidstone.

BLECHNUM SPICANT.

The very pretty and thoroughly evergreen Hard Fern, although of easy culture, hardly figures in collections so widely as it should. To some extent, this may be due to the fact that it resents the presence of lime either in the soil or in the water supply, and hence, if this fact be ignored and hard water be used, it dwindles and dies for no very obvious reason. If, however, a good compost of leaf-mould and good loam, the latter predominating, be given, it does well, either in pots or in the open, provided only rain water be used. Using these precautions we have still a vigorous plant of Blechnum spicant polydactylum which we found 30 years ago, and in "The Book of British Ferns" there is illustrated a magnificent specimen of Airey's plumosum, which created quite a sensation when exhibited in 1891.

The species is a solitary member of the genus in this country, and is characterised by producing two sets of fronds, barren and fertile. The former are of a long, lanceolate form, consisting of a midrib, flanked on both sides by bluntly pointed pinnæ, set closely together like a double comb. They are of a dark lucent green and very tough texture, whence the common name. These form a lax rosette, from the centre of which rise a number of erect, longer fronds, with very narrow pinnæ, only wide enough to carry two lines of fructificution, one on each side of the secondary midrib.

The linear sori or spore heaps are protected by a thin skin-like cover or indusium, which rises within the margin, and it is this independent indusium which distinguishes Blechnum from Lomaria, with which it is erroneously associated even by the Kew authorities, though in Lomaria it is the margin itself which is turned back as a protection, as in Pteris aquilina. The distinction is perfectly clear, and had been as clearly defined by the very botanists who now misname it, and, despite repeated representations, tacitly refuse to make a correction. The reality of the distinction is demonstrated by the fact that in B. s. anomalum, by no means a rare form, the fertile pinnæ are as wide as the barren ones, and the sori lie next the secondary midribs and far from the margin, a form Lomaria cannot possibly assume. Blechnum spicant is found in abundance in many parts of the country, forming extensive colonies in damp woods and on hedgebanks and similar positions, but always where rather humid conditions prevail. As a rule, the fronds run from six inches or so to a foot, but under very favourable conditions. We have waded through plants almost waist high, the roots then being in almost bog-like soil. Thoroughly established pot plants which have filled their pots with roots are therefore benefited by standing in saucers of water, rain water, of course.

Some pretty "sports" have been discovered. One of the prettiest of all, B. s. concinnum Druery, we have a particular affection for, as it constituted our first "find," and infected us with the fern fever, from which we have never recovered, and which eventually we have every reason to believe, had proved contagious to a large number of friends who have been incautious enough to approach us and the dangerous plant itself. The best varieties, with few exceptions, are all wild finds, very little having been done in the way of selective improvements. The exceptions are Airey's plumosum and Hartley's pretty little "crispissimum," the latter raised from an unpromising "strictum," which had yielded successive batches of the little gem named. There is also a serrata ramo-cristata form raised by crossing by Stansfield. The wild ones are B. s. ramo-cristatum Kinahan found in Ireland, and of which a counterpart was found in Strathblane, N.B., but has unfortunately perished. Our own "concimum," already mentioned, has long, narrow fronds, about half an inch wide, built up of two even rows of rounded, hollowed serrate pinnæ like little scallop shells. Barnes' lineare is equally narrow, but the pinnæ are rounded and smooth-edged, and, as a rule, so joined together that the frond is simply strap-shaped like a narrow, leathery Hart's-tongue. Forster's "plumosum," of rather mysterious origin, has wide imbricate fronds, with somewhat confluent pinnæ. Crested and polydactylous forms are represented by a find of our own "polydactylum," one by Miss Barraud—cristatum Barraudæ—and a fine form found long ago by Mr. S. B. Wollaston.

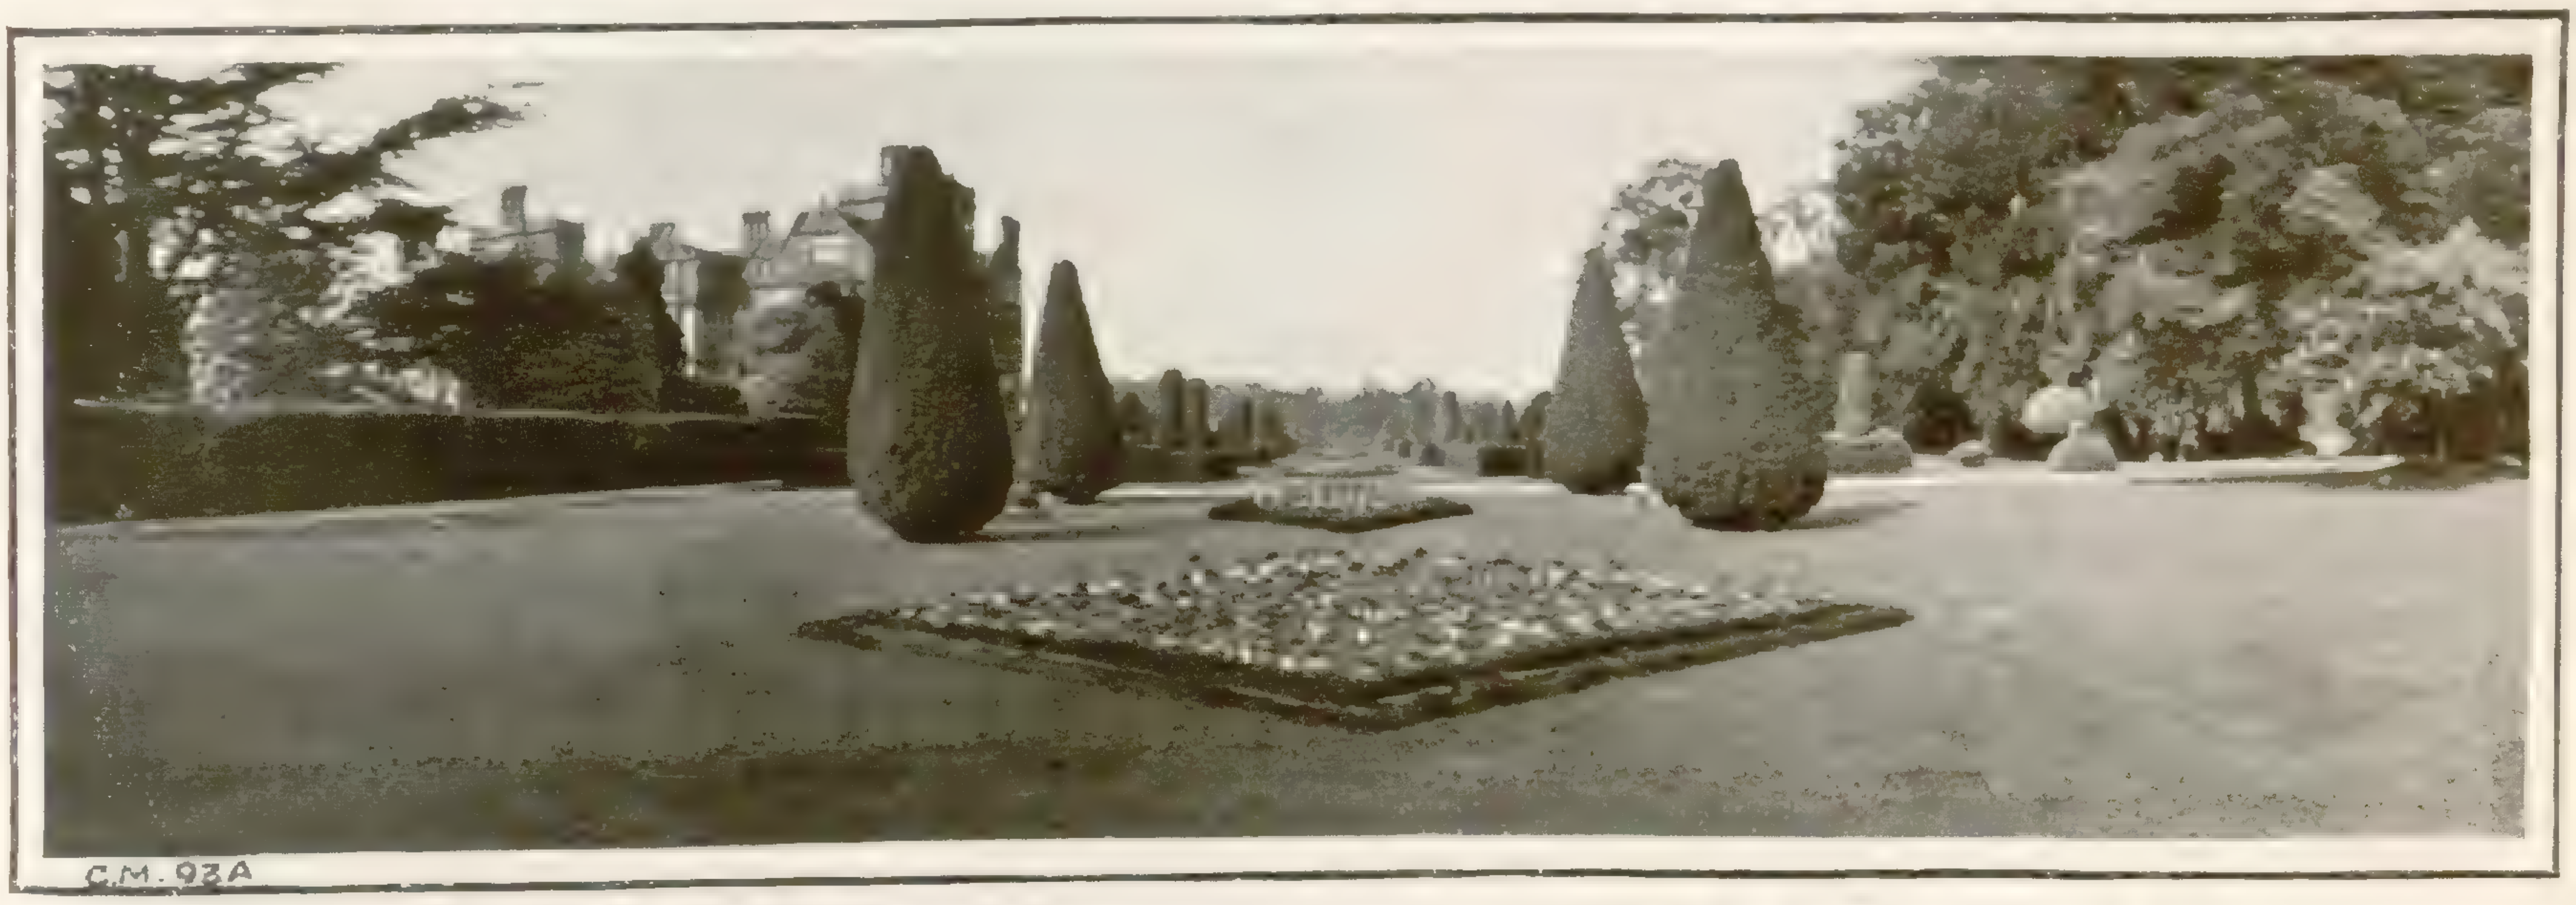
A number of strictum subconfluens forms exist. Maunderi is a dense, dwarf ramose cristata form, raised from a larger one found by Mr. Maunder.

As we have said, the species is thoroughly evergreen, and therefore retains its verdure well into the following season, the fertile fronds, however, die when the spores have ripened, and scattered; this, however, distracts but little from its merits as regards winter decoration, since they need only to be cut off when withered, leaving the attractive rosettee growth intact until a fresh batch rises in the spring.

C. T. Druery, V.M.H., F.L.S.

CLIPPED TREES AT CONDOVER HALL.

In connection with a recent article on "Hedges" we gave an illustration representing a view in the gardens at Condover Hall, near Shrewsbury. Clipped trees and hedges of yew are a great feature of these gardens, but in the clipping of the trees there has not been any severe striving after wondrously fantastic forms. Cones, pillars, and pyramids abound, and all are kept in excellent condition. We give another view in this garden, to further emphasise the value of dense well-kept hedges, and also to illustrate the utilisation of formally-clipped specimen yews in conjunction with brilliant summer bedding.



CLIPPED SPECIMENS AND HEDGES OF YEW AT CONDOVER HALL, SHREWSBURY.

SOIL STERILISATION.

In your esteemed paper (December 2) my name is mentioned in connection with a discussion on the "Sterilisation of Soils," and your correspondent at the Northern Fruit Congress states that I evidently wanted someone to wave the magic wand over my eelworm-infested soil and make it clean, and that I evidently had little faith in science, and left the room a disappointed man. With your permission, I will throw a little light on the subject, especially as to the statements I made, and my opinion respecting steam heating to sterilise soils.

It does not need much scientific knowledge to understand that if you can get eelworms within the reach of steam it must be death to them. This reminds me of the humour of a clown long since, who said, "There are always as good fish in the sea as ever yet were caught," but the retort came, "You may lose all your bait in trying to catch them." It seems to me that this subject of steam for sterilisation of soils to destroy eelworms is thrashed over much, because of the uncertainty of catching all the eelworms.

As a practical man, I have to face the problem in all its bearings. Fancy anyone who may be obliged to deal with hundreds of tons of soil by this method, and consider, after careful operation, that all had been destroyed that came within reach of steam, which we grant as probable. Now then, I am advised to steam rather than import new soil; but here we come face to face with the practical difficulty. In many large market nurseries thousands of plants are annually lifted and planted inside, carrying with them new colonies of eelworms to reinfest the soil, and yet we cannot think of steaming all the outside soil as well as that inside. I fill several large houses with chrysanthemums lifted from outside and planted inside, and we have reasons for thinking that our countryside is altogether infested with eelworm.

Your correspondent knows quite well that I appealed to scientific men to assist us in solving this problem of destroying the eelworm with chemicals. I have yet to learn that any serious investigations have been instituted to carry out experiments by either Government authority or any disinterested body of men. As the Board of Agriculture has money for experimental purposes, we look to receive some practicable scheme evolved by that department for the assistance of horticulturists.

We have many advertised remedies, but I have not found a cure among them hitherto. We have used gas lime with much benefit to cucumbers and tomatoes, and new soil is used for the former annually, but the eelworm destroys the roots of cucumbers by July and August, and the crop becomes very light, so that we may lose nearly half or a third of the crop. We have also saturated all our houses with a patent fungicide, but have not succeeded as we desire.

Am I unreasonable in my hope that eelworms may yet be destroyed by chemicals, either by fumes or direct application? I am not forgetful that since 1885 Bordeaux mixture has done much in the destruction of fungoid diseases on plants, and, later, that sulphide of potassium has come as a cure for mildew and rust. The County Council lecturer for Durham is now commending ground limestone, unburnt, as a preventive of finger-and-toe in swede turnips, and also as a cure for scab in potatoes.

I am a firm believer in the science that produces satisfactory results, but I am not to be set aside by science that will scarcely touch the subject with the finger-tips. At Newcastle I called for the attention of a man who had both the will and the faculty to assist us in this difficulty, and on the spur of the moment there came to my mind the name of Mons. Pasteur, and I said, "Oh, if we had one Pasteur to assist us out of our difficulty." That great scientist was once met in a street in Paris, and embraced by a friend, who said to him, "You must come out to my district and help my poor people, who are in danger of losing their industry through disease in silkworms." Pasteur went and found a remedy. That is the class of man that I am calling for. But I only got the answer of "the magic wand" in response.

Private gardeners know little generally about the destructive influence of eelworms. During more than 40 years' connection with private gardeners, I do not remember the subject cropping up in private conversation, but, according to trade papers, eelworms are found to infest many kinds of soils and plants in large districts. We growers may be ignorant of a remedy, even though this may be near at hand, but we freely confess that ignorance, if, by making it known, we can learn from any source of a practical remedy, cheaper, and more certain than sterilisation by steam, and even this idea, if my memory serves me rightly, we got from the United States.

George Harris.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

GENERAL REMARKS.—The work in the houses will now be confined principally to clearing operations. While we have so many of the different species and hybrids in the various divisions in a more or less dormant state, the opportunity is afforded for a careful examination of the plants, as scale and other insect pests may have become secreted about pseudo-bulbs and foliage. One is often asked to recommend some safe insecticide for sponging purposes. There are several on the market quite up to all that is claimed for them by the manufacturers, but the unfortunate part is, that users do not always comply with the instructions, consequently one hears complaints of injury. We have found that spraying is generally effective for thrips and greenfly, but where black thrips have been on the plants, they are not destroyed altogether by spraying, especially where the eggs are laid on the under sides of the leaves, and other protected portions of the plants. Sponging, therefore, becomes necessary, and there is nothing safer than warm water with a little soft soap added—not sufficient to colour the water. This will not only remove the pests, but dust and other settlement from the leaves. At this season all necessary washing and cleansing of the houses should be attended to, for as soon as we come to the turn of the days, there are so many calls on one's resources of labour that it is advisable to have all work of this kind as forward as possible while work is not so pressing.

DECIDUOUS DENDROBIUMS.—Many of the early-flowering dendrobiums have their flower buds prominent on the pseudo-bulbs. Where it is desirable to have plants in flower early in the New Year, the most forward should be transferred from their resting quarters to positions in the warmer divisions, where they may obtain the conditions necessary to encourage the development of the flower buds. When endeavouring to get plants into flower thus early, there is generally a tendency among them to produce side growths, instead of flower buds. There are two causes for this; the chief one is want of proper ripening in the early autumn. The other is too liberal treatment. Plants are often taken from their resting conditions and placed in the hottest position obtainable, where the atmosphere is at the point of saturation at all times; here, even without any root moisture whatever, the conditions are sufficient to keep the plants in a normal state; but in cases where water is given the root growth is often obtained instead of flowers. It is never safe to be liberal to dendrobiums until the flower buds are seen to be separating from each other.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

GLOXINIAS for early flowering may be produced by a selection of the earliest ripened corms. These may be left undisturbed in the pots in which they flowered, but the surface soil should be removed and a top-dressing of good fibrous loam, peat, and well-decayed sheep manure in equal parts be given. Place the plants in a light position, and as near the glass as circumstances permit. A shelf in the stove may often be found an ideal position for early gloxinias. As soon as the roots are active and growth is progressing, light feeding may with advantage be afforded, and given more frequently as the foliage develops and the flower buds appear. An early display of gloxinias is always appreciated, and the flowers are of great value when cut and tastefully arranged with asparagus growths or trails of smilax, for dinner-table decoration.

SEEDLING GLOXINIAS cultivated expressly for winter-flowering are now developing their best blooms; the plants will need extreme care at this season, for excess of watering will end in disaster. After flowering the corms must be subjected to a thorough ripening process by exposure to the sunshine, and a gradual reduction of water to the roots.

HIPPEASTRUMS.—Seedlings raised early last season may be kept nearly in a state of rest until early in the year, and they will then commence growth with renewed vigour and make rapid progress during the early spring months. For producing an early supply of flowers of these bulbous plants, the old bulbs will need to be specially treated. A careful selection should be made of the strongest bulbs for forcing into bloom from Christmas onwards, until the seasonable time for the general flowering of the main stock. Experience and long observation have proved that for early forcing the best results are obtained by a selection of thoroughly ripened and established bulbs, which have not been repotted the previous year. After flowering it will be found advisable to repot those that may require such treatment at this stage, and any new roots formed must be carefully preserved; but only the loose soil removed. If bulbs are liberally treated by regular feeding, every third year is generally sufficed for repotting, and an excellent plan is to divide the stock into three batches, each separately labelled, the newly-potted batch each year being kept for late flowering. The early bulbs now selected will not require water until the flower stem is visible. If the bulbs are now thoroughly overhauled and cleansed, much after labour will be saved.

GENERAL REMARKS.—The present season affords an excellent opportunity for a thorough washing and cleansing of the houses. I have found nothing more satisfactory than hot-water and soluble paraffin soap for scrubbing down woodwork, stages, floors, etc. The glass, both outside and indoors, is all the better for a good wash down. After the work is satisfactorily concluded, attention must be given to lime-washing the walls, and the renovation of permanent borders where creepers are growing. All pruning and thinning out of weak or undesirable wood should be carried out without delay. Then the occupants of the plant stoves should be sponged with weak insecticide, the pots washed, new shingle put upon the stages, and a general rearrangement of plants tastefully carried out.—John Donoghue, Bardon Hill Gardens.

FRUITS UNDER GLASS.

EARLY VINES.—The weather has been very wet and dull, and rather against early forcing, but still at this early stage it does not matter so much as when the young growths are pushing, for it is then sunshine is so necessary to make our efforts successful. In the last calendar I advised an increase of 5 deg. of heat, and now another 10 deg. must be added, making the temperature up to 60 deg. This will be sufficient until the growths are further advanced. Maintain the atmosphere sweet by occasionally giving ventilation. Keep the soil from getting dry near the hot-water pipes, and spray the rods gently in genial weather. As soon as an even break has been obtained the rods should be tied up to the vines, using fine tarred twine for the purpose. In houses built for vines the wires should be 2ft. from the glass, as at that distance the temperature is fairly even.

LATE HOUSES AND MUSCATS.—Wherever practicable it is a good plan to cut all grapes as soon after this date as possible, or at least as soon as the new year comes in, and the vines should then be pruned and dressed, as advised for the early house. Sometimes on the back walls of lean-to houses plants are grown, and these also should be detached and thoroughly cleaned, and the wall should be given a good coat of hot lime to which some petroleum and sulphur has been added. This mixture should be well brushed in, and if done twice over all the better, as a better colour will be obtained, and the result be more permanent.

PEACH HOUSES.—The early peach-house should have some additional heat, now that the buds will soon be bursting, and 50 to 55 deg. will be a good temperature to maintain while the trees are in bloom, admitting a little air on all favourable occasions. Keep the air rather drier during the flowering period, and brush over the flowers at regular intervals with a hare's tail.

EARLY STRAWBERRIES.—These should have a little more heat as soon as the flower spike is showing; a temperature of 55 deg. will be sufficient for the present, as forcing must be proceeded with cautiously. Syringe gently on fine days, especially under the foliage.

GRAPE ROOM.—Look over the bunches frequently, and cut out all bad berries. Keep the temperature as even as possible, about 50 deg. is quite enough. — W. A. Cook. Leonardslee Gardens.

THE FLOWER GARDEN.

VIOLETS IN FRAMES.—Much difficulty is experienced in some gardens at this season of the year in maintaining a supply of violets, especially where heavy fogs are frequent. In such places the foliage is attacked by disease and damp, and strict attention is necessary to keep the plants in a healthy condition. To accomplish this, free ventilation must be afforded at every available opportunity, removing the lights from the frames on bright days, and only closing them when the weather is foggy or frosty. If leaf spot occurs, it must be attended to immediately it is noticed, and before it does serious damage; spray with a solution of sulphide of potassium, half an ounce dissolved in a gallon and a-half of water. The soil should be frequently stirred with a hand fork to prevent it becoming green and sour. When water is required, it should be given in the morning, to allow the foliage to dry before night comes with its lower temperature. A little stimulant in the way of artificial manure is beneficial, and should be lightly worked in with a hand fork before watering.

PERGOLAS.—An examination of all woodwork used in the construction of pergolas, arches, etc., should be made now, and all decaying timber replaced with new. Oak and elm are the most suitable materials, and, if possible, should be well seasoned before use.

THE BOG GARDEN.—Slugs are very troublesome among many of the dormant plants, and a close watch must be maintained to prevent any losses from the activity of these pests. The resting crowns of the cypripediums are often destroyed by slugs, and consequently the flowers which are looked for next season never appear. A careful application of one of the approved preparations for the destruction of evil pests usually proves effective. Encircling the roots with strips of tin is sometimes advised, but in many instances the slugs are too close down amongst the roots for this to be of much service. Occasional top-dressings are beneficial, and a few pieces of charcoal should be mixed with it, to keep it sweet. Primula rosea has a tendency to work out of the soil, and the roots become bare if not top-dressed. P. sikkimensis is extremely difficult to keep after flowering for one or two seasons, therefore one should always have a reserve stock of pot plants for putting out in the spring to fill up vacancies. Saxifraga peltata has a habit of encroaching, and its thick rhizomes creeping about will in time destroy some of the choicer plants, if not checked.

SNOW.—When a heavy fall of snow occurs no time must be lost in removing it from the shrubs, to avoid the risk of their being broken down by the weight. This can be accomplished with the aid of a long bamboo pole, slightly shaking the branches with it, but dealing with them in as gentle manner as possible to avoid bruising the bark or breaking the shoots.

DRAINS.—All faulty drains should be examined and broken pipes replaced. Where choked it is often necessary to break into them and push the cleaning rods through, making good the breaks when the pipes are clear.—E. C. Pooley, Gnaton Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at sixpence per line, the minimum charge being two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

There was no general exhibition at Vincent Square on December 19, but the various committees met, the members signed the attendance book, wished each other the compliments of the season, and discussed the few novelties placed before them. The Fruit Committee had two dishes of apples to consider; the Floral Committee had half a dozen subjects before them, while the Orchid Committee, which met in the Lecture Hall, had to adjudicate upon a goodly number of plants, and there was a quite bright display around them.

FLORAL COMMITTEE.

Messrs. James Veitch and Sons, Chelsea, exhibited a new Buddleia named B. officinalis (A.M.): this was collected by Mr. E. H. Wilson, and should prove a useful conservatory plant, as its clusters of pink flower are sweetly honey-scented. It is in the way of B. asiatica, and has sage-green leaves, with white under-surface.

A number of chrysanthemums were staged, including a mauve anemone-centred variety from Mr. Cresswell, gardener to P. Bullivant, Esq., Holmwood, Eden Park, Beckenham; Fred Rose, Patty, and H. Douche, red-pink, and yellow decorative varieties respectively from Messrs. W. Wells and Co., Merstham; and Christmas Bronze, a loosely incurving variety from Mr. W. Iggulden, Lock's Hill Nursery, Frome.

ORCHID COMMITTEE.

There was a capital little display of orchids in the Lecture Hall. Mr. Hopkins, gardener to F. A. Wellesley, Esq., Westfield, Woking, showed Brasso-cattleya Veitchi (the F.C.C. variety), carrying a pair of very big brilliant flowers, each with an enormous lip; and Lælio-cattleya Rubens, Westfield var., a charming form of the hybrid between Cattleya Hardyanum and Lælio pumila.

Mr. Edward V. Low, Vale Bridge, Haywards Heath, brought up some very bold cypripediums, such as C. Samuel Gratrix, C. The Gaekwar, C. Maharajah, and C. Beryle, West Point var., and C. The Nizam, the last-named resulting from a cross between C. Helen II. and C. insigne Harefield Hall.

Messrs. Charlesworth and Co., Hayward's Heath, contributed Oncidium anthrocrene, an old strong-growing species, with brown and yellow flowers of moderate size; Odontioda Cooksoni venustum, a brilliant crimson form with a very attractive white apex to the lip; Cypripedium Actæus Durbar (A.M.), of great width and substance, but a trifle dumpy; and Lælio-cattleya Myrrha flavescens, pale yellow-buff and purple.

From Messrs. James Veitch and Sons, Chelsea, came the handsome Lælio-cattleya Nella (F.C.C.), a fine purple hybrid; Cypripedium Snowdon, a yellow and white hybrid in the way of C. insigne Sanderæ; and C. Clionia, a useful hybrid between C. Actæus and C. insigne Harefield Hall.

Mr. H. Alexander, orchid grower to Lieut.-Colonel Sir George Holford, Westonbirt, Tetbury, Gloucester, brought up Cypripedium Lord Wolmer Westonbirt var. (A.M.), an attractive cross between C. Leeanum and C. Euryades leonardianus; this has bright purple spots on the white dorsal sepal; the ventral sepal is especially broad, two inches across, white and green, with purple spots.

Mr. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate, submitted the big, bold Cypripedium insigne Gatton Park var. (A.M.), which, we understand, is the result of crossing C. insigne montanum magnificum with C. insigne Harefield Hall; it has a big, heavily spotted dorsal sepal, and Odontioda Diana Gatton Park var., very bright clear red, the odontoglossum parent in this case is O. amabile.

From Messrs Sander and Sons, St. Albans, came some bold cypripediums, the best of which was C. Royal Sovereign (F.C.C.), a handsome hybrid between C. Hera robustum and C. Martin Cahuzac; it has a huge blush white dorsal sepal, freely spotted with bright purple.

Very fine was Odontoglossum crispum Alcyone (A.M.), carrying a grand spike of fourteen large and beautiful blooms, white and blush, with a few red-brown spots on the sepals, and a cluster of red-purple dots on each petal. This was from J. Gurney Fowler, Esq., Glebelands, South Woodford.

FRUIT AND VEGETABLE COMMITTEE.

Mr. Lee Hubble, Faversham, Kent, showed a bright Pearmain-shaped apple named King George V.; and Mr. A. Hussey, Crowthorne, Berks, showed a very heavy, solid seedling apple, unnamed, that seems to possess no small merit.

National Rose Society.

The annual general meeting of this society, held at the Westminster Palace Hotel, at 3 p.m. on Thursday, December 14, was presided over by the President, the Rev. J. H. Pemberton.

There was a good attendance, and the room was well filled with well-known rosarians, which included Rev. F. Page Roberts, Rev. J. B. Shackle, Messrs. C. E. Shea, E. J. Holland, G. W. Cook, J. Collingridge, G. Gordon, V.M.H., O. G. Orpen, A. H. Darlington, A. Tate, H. Mount, J. Mattock, C. Cant, J. Jefferies, J. T. Strange, F. Cant, G. Prince, G. Paul, V.M.H., G. Prior, A. H. Brown, J. T. West, G. D. Pawle, W. Tayler, R. Pinches, and G. Burch, and Dr. Williams.

Before the report was placed before the meeting the President read a letter from Mr. E. Mawley, V.M.H., who was prevented from attendance owing to illness, as follows:

"Dear Mr. President,—I cannot tell you how disappointed I am not to be able to be with you to-day. For after attending 34 of these annual meetings of the society it has become a pleasant habit with me to look forward to the next one, as each year's end comes round. I had quite hoped and expected to have joined you this afternoon, but it has been decreed otherwise. I feel sure you will all be pleased with the society's present position, in that we have now over 5,000 members, and knowing all that that means in the interests of the rose. I well remember the time, and our President will no doubt do so as well, when for years we felt we should be perfectly happy if our membership could be only advanced to 500. I trust this meeting may be a good one, and that you will all enjoy the conversazione, which promises to be the best attended we have yet had. Do not omit to see the coloured photograph of the basket of roses sent to H.M. the Queen. Wishing you all a happy Christmas and a better rose season next year than in 1911, I am, yours sincerely, Edward Mawley."

REPORT FOR THE YEAR 1911.

We give a few extracts from the report:

The Council congratulate the members upon the continued satisfactory position of the society. For the first time in the history of the society the number of members exceeds 5,000. The membership has doubled in the last four years, and is still increasing rapidly.

The Metropolitan Exhibition was again held in the Royal Botanic Gardens in Regent's Park. It took place this year on July 7, and proved one of the largest the society has yet held. The most noteworthy feature in regard to this exhibition was that it occupied a canvas structure, with a level-boarded floor, which had originally been erected for the purposes of a large ball, so that for the first time a view of nearly the whole of the exhibition could be seen by members and other visitors to the show. This arrangement also had the great advantage of permitting a free circulation of the visitors to the show, and a close inspection of all the exhibits.

The provincial show took place at Ulverston on July 19. Unfortunately, owing to the excessively hot and dry character of the weather from the beginning of July, this exhibition proved much less extensive than usual. The arrangements were admirably carried out by a large staff of stewards, under the able direction of Mr. F. J. Harrison, hon. secretary of the North Lonsdale Rose Society.

The autumn exhibition, the eighth of the series, again took place in the Royal Horticultural Hall, Vincent Square, Westminster, and, when is borne in mind the trying character of the season for roses throughout the country, it must be regarded as having been a surprisingly good one.

On the occasion of the Coronation of His Majesty King George V., the society had the honour of presenting a basket of choice rose blooms to Her Majesty the Queen, and also to Her Majesty Queen Alexandra, which were most graciously acknowledged by their Majesties.

At a special general meeting of the society held on April 25, a number of alterations and amendments were made in the rules and bye-laws of the society, with a view to ensure a more satisfactory method of electing the officers and Council at the annual general meeting. On the same day a rose conference was held which proved an undoubted success. The President delivered an address on "Roses for the Garden," which was followed by a discussion.

During the course of the past year the following publications have been issued to the members. In March, the "Rose Annual for 1911"; in October, the 1912 edition of the "Official Catalogue of Roses"; and in November last the 1912 edition of the "Handbook on Pruning Roses." The Council again feel that they cannot too warmly express their thanks to the Publications Committee for their labours during the year.

At the last annual general meeting the Dean Hole Memorial Medal was presented to the hon. secretary of the society, Mr. Edward Mawley, for his invaluable services as hon. secretary of the National Rose Society extending over a period of thirty-three years, and for his efforts on behalf of the rose.

The Council announce with regret the death in April last of one of the society's vice-presidents, Mr. R. N. G. Baker, of Heavitree, Exeter. The Rev. Alan Cheales, another veteran and respected rose grower, has passed away from among us during the year.

During the past twelve months 886 new members joined the society. Allowing for the losses by death and resignation, the total number of members is now 5,125.

On the occasion of the jubilee of the Southampton Royal Horticultural Society, it has been decided to hold a rose show in conjunction with that society on June 26, 1912. The Metropolitan Exhibition will take place in the Royal Botanic Gardens, Regent's Park, on Tuesday, July 9. The provincial show will be held at Belfast, in connection with the Irish Rose and Floral Society, on Friday, July 19. The autumn exhibition will be held in the Royal Horticultural Hall, Vincent Square, Westminster, on Thursday, September 12.

The receipts from all sources during the past year, including a balance from the previous year of £364 12s. 10d., amounted to £3,516 13s. 6d., and the expenditure to £3,027 17s. 8d., leaving a balance at the bankers of £488 15s. 10d. after £250 had been placed to the reserve fund. The reserve fund now stands at £1,250.

Mr. G. W. Cook, the treasurer, made a few comments upon the balance-sheet, which he read, showing the differences between the 1910 and the 1911 accounts; he said the income from show receipts was considerably less than usual, due largely to the great increase of membership. Publications had not cost so much, but postages and telegrams had become a heavier item. The exhibitions cost about £1,400, or nearly half the total expenditure, and yet comparatively few members competed for or won prizes—though these latter amounted to about £800.

The President then moved the adoption of the report and financial statement, and said the society was not merely an exhibition society, but, unlike other societies dealing with a special flower, the non-exhibiting members were catered for by means of publications. He pointed out that in the coming year the society proposed to hold an extra show at Southampton, another rose conference, and to entertain the foreign rosarians who would be coming over for the great International Exhibition in May. He hoped the society would continue to progress as rapidly as in recent years. Mr. J. Jefferies seconded the motion, and said that when he joined the society there were only about 200 members.

Mr. E. J. Holland expressed the regret all felt at Mr. Mawley's absence and its cause, and suggested that a message of sympathy should be sent him. Mr. Holland pointed out that in the last six years the increase of membership was very considerable, but in 1911, though it was great, it was not so large as in 1910, but he thought this need not give rise to any doubts as to future progress. The gate money had decreased, and he thought this was due somewhat to the fact that the rose show was held too closely to the great three days' show of the R.H.S. He thought exhibitions should be the great feature of the society's work, and should be maintained in every possible way, though at the same time he did not wish the publications to suffer. Mr. Darlington thought the society did not give sufficient privileges to guinea members, such as to induce others to raise their subscriptions to that point, and he hoped something might be suggested to alter this state of affairs. He made a kindly reference to the decorative roses at the society's autumn show, and suggested these should be increased, but so arranged as to encourage all classes of members. The motion was then put and carried.

Mr. George Paul moved that an honorarium of £100 be granted to Mr. Mawley for his services during 1911; this was seconded by Mr. Cook, and carried unanimously. It was stated that the Council had granted £105 to Mr. Mawley as a token of love and respect, to meet heavy expenses incurred by the severe operation he had recently undergone. Mr. Cook said that he believed in the earlier years of the society's work Mr. Mawley could not have spent less than £1,500 in cash from his own pocket to further the interests of the society. The meeting signified thorough approval of the Council's action, and considered they were only in some measure repaying the debt owing to Mr. Mawley.

NEW BYE-LAW.

Mr. C. E. Shea briefly proposed the following bye-law which, he said, was based on the experience of the council and of those who had formed the International schedule: "By the word Nurseryman is understood a person who maintains a garden, or other horticultural establishment, for the purpose of gaining a livelihood, and who intends it to return him an annual profit. By the word Amateur is understood a person who maintains a garden with a view to his own use and enjoyment, and not for the purpose of gaining a livelihood. The fact of his occasionally disposing of surplus produce, or new varieties, for money, does not change him into a nurseryman, unless the whole maintenance of the garden is intended to return him an annual profit; but no person shall be allowed to compete as an amateur who sells rose plants (except when giving up possession of the place where they grow, and in the case of new seedlings or sports), rose blooms or buds for budding. No lady may exhibit as a lady amateur who is either engaged in the floral or horticultural trade or as a paid gardener herself, or is a resident member of the family of one engaged in such trade or employment. To exhibit in the ladies' artistic classes a lady must either be a subscriber to the society, or else a member of the family, and of the household, of a subscriber. Any objection raised as to the rightful qualification of an exhibitor shall be referred to the council for arbitration, and their decision shall be final and binding on all parties."

Mr. Darlington seconded the motion, and said the new bye-law was for the purpose of more strictly defining the amateur member.

The President added a few explanatory words, and Mr. Christy asked whether, in the case of a club possessing a club garden, and selling blooms to its members, would such members be ineligible to compete as amateurs, because, virtually, they were sellers, through the club manager. The President thought they would be eligible, but said such a matter needed consideration in committee. Mr. Shackle suggested that the second and third sentences allowed an amateur a very large amount of latitude, and were thus not sufficiently safeguarding the nurserymen. The President pointed out that the whole by-law applied only to people who competed or exhibited and did not otherwise define an amateur. After a few other remarks the motion was put, and carried.

Mr. Colin Romaine moved thanks to officers and council in a few appropriate remarks, and this was unanimously accorded. The President said the house list of officers and council was elected, and requested that Mr. C. W. Edwards' name, inadvertently omitted, should be added, and this was allowed without dissent.

The meeting then unanimously forwarded the following telegram to Mr. Mawley: "Members National Rose Society greatly regret your first absence from annual meeting for thirty-five years, and send hearty greetings and best wishes for your early and complete restoration to health.—President."

The Rev. F. Page Roberts humorously moved a vote of thanks to the president, which was heartily accorded, and briefly responded to, and the meeting then closed.

CONVERSAZIONE.

At the conclusion of the annual meeting the members took part in the conversazione, which is now a recognised part of proceedings. The function was again a success, and most enjoyable.

North of England Horticultural Society.

DECEMBER 13.

At a well-attended meeting of the above society, Major J. W. Dent (chairman of the Yorks Agricultural Committee and chairman of the N.E.H.S.) in the chair, papers were read on "Compensation for the Destruction of Diseased Plant Stock" by Dr. Burtt, York (British Botanical Association); Mr. W. F. Emptage, and Mr. J. Smith, F.L.S., Durham.

The first speaker was Dr. Burtt, who submitted to the Conference the following resolution:

"That this Conference views with concern the persistent increase in this country of the pests American blight of Woolly Aphis (Schizoneura lanigera) and Currant Big Bud Mite, or Black Currant Gall Mite (Eriophyes [Phytoptus] ribis), both causing dangerous and contagious diseases of plants, and urgently requests the Board of Agriculture and Fisheries to place them on the schedule under the Destructive Insects and Pests Acts 1877 and 1907."

During the past nine months he said they had all caught up much of the enthusiasm of the secretary and had already studied the text of Professor R. A. Harper Gray's instructive lecture on these pests. It was not therefore necessary to take up their time with an account of the life-histories of woolly aphis and currant big bud mite, or even to dwell upon their present wide distribution. Sufficient to know that in adopting the resolution they were at least making an endeavour to set the machinery in motion which is designed for the purpose of eradicating these dangerous insects from our country.

This should be the result, at any rate, in theory; but how about the practical results, assuming that the request is complied with?

We have our Destructive Insects Act of 1877 (the first recorded instance of legislation against specific plant diseases). We have the supplementary Act of 1907. We have orders and regulations from time to time of the Board of Agriculture and Fisheries, and yet we have with us still to a varying extent such old enemies as: The large larch sawfly (Cumberland, 1904) (not given as a scheduled pest in Board of Agriculture Leaflet 155), black scab, or potato canker (Synchytrium endobioticum), tomato leaf-spot, American gooseberry mildew, and others.

It may not be out of place to consider for a moment what are the causes which tend to prevent the successful combating of plant diseases.

A word in regard to the question of compensation is necessary. This, you may perhaps be aware, formed the subject of a letter to the secretary some months ago, and it may be that to some extent the idea of the present Conference was suggested by that letter.

Turning to the legislation on the question, Dr. Burtt said it would be found in Article 3 of the Destructive Insects Act, 1877, that where the Privy Council may by order direct or authorise the removal or destruction of any crop, they may direct or authorise the payment by the local authority of compensation, and the local authority shall pay the same, subject to certain provisions as to amount, etc. This article is endorsed in the Destructive Insects and Pests Act, 1907, with the proviso, that the Board of Agriculture and Fisheries shall not make an order for compensation unless the local authority consent to make the payment.

These may be tabulated as follows:

I.—Ineffectual legislation.

II.—Want of accurate knowledge of plant pathology.

III.—Indifference.

In the first category may be mentioned:

(a) The absence of statutory ports of entry for imported plants, etc., with compulsory inspection and fumigating stations connected therewith.

(b) The delegation of duties under the Acts above mentioned to local authorities under the Diseases of Animals Act, 1894.

(c) An uncertain scheme of compensation—the question of compensation being at the discretion of the local authority.

(d) Absence of compulsory and periodic inspection of growing stocks by expert officials.

Dr. Burtt described at some length what is being done in Canada and the United States in combating plant diseases and injurious insects, and suggested that in this country the delegation of duties under the Destructive Insects and Pests Acts, 1877 and 1907, to local authorities acting under the Diseases of Animals Act, 1894, might with advantage be altered to the extent of appointing a staff of horticultural inspectors with powers similar to those obtaining in Canada.

After instituting a number of inquiries in various parts of the country, we had not, he stated, been able to discover from the replies so far sent in either that an order has yet been made for compulsory destruction—(with one exception where destruction by order of the local authority resulted in "quite unimportant" loss), or that compensation had yet been granted.

On the other hand he had met with an instance (previous to the issue of the American Gooseberry Mildew Order of September, 1911) where, after inspection by an officer of the Board of Agriculture, followed by the voluntary destruction of stock to the value of over £150, no compensation could be claimed, the Board declining responsibility.

He suggested that the eradication of some of the most dangerous and destructive insect and fungus pests, some of which have long resisted the individual efforts made against them, would be hastened if compulsory destruction, accompanied by a fair and certain compensation, were more generally adopted.

In making this suggestion he did not wish to underestimate the value of the efforts which many nursery firms and private growers are making to combat disease. He could, however, endorse the opinion which obtains, he believed, in the trade, that legislation against disease is not needed. Experience tends to show that individual efforts, stimulated as they doubtless are by the thought of maintaining a great and well-deserved reputation, are frequently rendered of no avail, and that the only certain cure lies in the direction of effective legislation.

Mr. Emptage stated the commercial aspect of the case. He pointed out that in our Colonies and elsewhere, the fumigation of general nursery stock was compulsory, also the destruction of affected fruit. Generally speaking, wholsale compulsory destruction could not be practically carried out—spraying should, however, be made compulsory, and would prevent, check, and limit the spread of disease.

Mr. J. Smith advocated the inspection of markets. Packing materials, greengrocers' refuse, cork dust, and refuse from docks should be burnt, and not allowed to go on to manure heaps, etc., and spread disease up and down the country. The Ipswich Natural History Museum has a rich collection of insect life, collected from such sources. Much good could undoubtedly be done in instructing the public in good cultural methods, thereby lessening the spread of disease.

Mr. W. Cuthbertson, of Messrs. Dobbie and Co., Edinburgh, stated that the export of potatoes to Australia was at present an impossibility owing to the refusal of the Board of Agriculture to grant clean bills of health to exporters. Any compensation should come from Imperial sources. He recommended the self-denying ordinance of the Government of South Africa in placing the work of the agricultural authorities outside party politics for three pears. In England a similar resolution would enable much practical progress to be made. He advocated the establishment of a research station in the North of England—conditions of climate, etc., demanded such a station.

Professor Seton (Leeds University) pointed out the need for inspection at our entry ports of both stocks for fruit trees and also fruits.

After further discussion Major Dent laid stress on the necessity for only destroying diseased stock, and that compensation for diseased stock alone should be given and paid for out of the Imperial Exchequer. In agriculture the principle adopted was to compensate a man for stock apparently healthy but infected by accident or misfortune by contact with diseased stock.

The Chairman then put the following resolution, which was carried unanimously: "That this Conference urges upon the Board of Agriculture and Fisheries the urgent necessity (1) of a staff of trained horticulturists as inspectors to carry out the provisions of the injurious insects and pests orders; (2) of more stringent precautions against the entry of diseased plants, fruits, and vegetables, and packing materials used for same, at our ports; (3) of the establishment of a station for horticultural research in the North of England and other parts of the country."

Scottish Horticultural Association.

The December meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 5th inst. Mr. Massie, the president, was in the chair, and there was an attendance of 120 members.

Mr. Thos. Anderson, M.A., B.Sc., Edinburgh and East of Scotland College of Agriculture, delivered a lecture, illustrated by lantern slides, on "Insects and Flower Pollination." It proved of great interest, and on the motion of the Chairman, the lecturer received a very cordial vote of thanks.

The exhibits included new single chrysanthemums Miss Callander, a creamy white (awarded First-class Certificate), Mrs. G. F. Eyre and Miss E. L. Cowan (awarded Certificates of Merit), and Mrs. R. C. Cowan, from Mr. W. G. Pirie, Dalhousie Castle, Midlothian; new single chrysanthemums Lady Helen and unnamed seedling, from Mr. D. McLean, Raith, Kirkcaldy; Chrysanthemum Felton's Favourite, from Mr. James Bruce, Davidson's Mains, Midlothian; chrysanthemums and Christmas roses from Mr. Chas. Comfort, Broomfield, Davidson's Mains; and collection of chrysanthemums from City of Edinburgh Distress Committee's farm at Murieston, Mid-Calder, per Mr. Cairns.

Captain Stirling of Keir, Dunblane, was nominated as honorary president for 1912, in succession to Sir John Gilmour, Bart.; and Mr. Massie was nominated for re-election as president. Messrs. J. Phillips and D. W. Thomson were nominated for the two vacancies in the vice-presidencies, and there were eleven nominations for the seven vacancies in the council. The annual business meeting will be held on January 16 next, when the office-bearers will be elected, and the revised constitution and bye-laws will be submitted for adoption.

Mr. King, the Convener of the Finance Committee, stated that there was a balance of income over expenditure of approximately £25 on the chrysanthemum show, notwithstanding the very bad weather which was experienced on the first and second days. It was agreed to hold a three days' show in 1912, the dates to be November 14, 15, and 16.

On the invitation of the Honorary President-elect, it was agreed that the annual excursion in 1912 be to Keir, and Captain Stirling was very cordially thanked for his kind invitation.

Royal Scottish Arboricultural Society.

FORECAST OF SCOTTISH FORESTRY COMMITTEE'S RECOMMENDATIONS.

The annual general meeting of the Aberdeen Branch of this Society was held in the Botany Classroom, Aberdeen University, with Mr. Sydney J. Gammell, of Drumtochty and Countesswells, in the chair.

In moving the adoption of the treasurer's report, the Chairman said the branch could congratulate itself on its satisfactory financial position. They started the year with a credit balance of £20 11s., and finished with a balance of £13 10s. 10d. They had to consider that, not only had the ordinary expenses been met, but that also a grant of £10 had been made to the branch library. The report, duly seconded by Mr. C. S. France, Aberdeen, was unanimously adopted.

The meeting then proceeded to elect office-bearers for the coming year. The Chairman asked the meeting to allow him to retire from the position he had occupied for the past three years. He felt that the honours should go round, but if he had a chance of occupying the chair again at some future time he would be only too pleased to do so. He begged to propose as his successor Mr. Alexander Forbes Irvine, of Drum. This was seconded, and heartily agreed to. Mr. Irvine, who is a very popular landed proprietor in Aberdeenshire, then took the chair, and thanked the meeting for the honour conferred on him. Sir John Fleming, of Dalmuinzie; Mr. John Michie, M.V.O., factor to the King on the Balmoral Estates; Dr. James W. H. Trail, professor of botany in Aberdeen University; and Mr. Gammell, the retiring president, were appointed vice-presidents of the branch. Thereafter a large and representative committee, comprising landed proprietors, factors, and foresters, was appointed. Mr. G. D. Massie, solicitor, 147, Union Street, Aberdeen, was cordially re-elected secretary and treasurer.

Sir John Fleming, in proposing a vote of thanks to Mr. Gammell for his services as president of the branch during the past three years, remarked that during the long time he had been a member of the society he had come into contact with all sorts of forestry experts, but he found Mr. Gammell had a greater knowledge of forestry than almost any other man he had come across. His estate was a model, as he happened to know, being one of the Forestry Commission that had been lately tramping throughout Scotland in this connection. Sir John's remarks were heartily endorsed by the meeting.

SCOTTISH FORESTRY.

This part of the proceedings over, the meeting settled down to hear an address by the Right Hon. Robert Farquharson, of Finzean, Aberdeenshire, on "The Past, Present, and Future of Forestry." The genial Doctor opened his address by saying that it was quite evident forestry was at this moment much in view. There had been a great deal of attention directed to it lately. There had been debates in Parliament, and debates before their own association. They had got a lectureship in this subject in Aberdeen University now, and it was hoped that in the not very distant future they might see a chair of forestry established in Aberdeen University. This would enable the whole subject of forestry to be brought definitely to the front by the establishment of a definite professional chair. A deputation that waited upon the Chancellor of the Exchequer not very long ago had made a very strong impression on the mind of the Chancellor, and that gentleman had shown by his sympathetic attitude that he was quite aware of the great importance of the subject of forestry. The Chancellor had pointed out that there was a very general agreement that some steps should be taken in afforesting the waste lands of the country. They were behind every civilised country in the world, and, declared Dr. Farquharson, he felt sure all there would agree with him when he said that this country of ours could grow better trees than could be grown abroad. The Chancellor had announced what he called a Development Grant. It began with the comparatively small sum of £200,000 annually for purposes of agricultural education, the development of forestry, and a large number of really important matters connected with agriculture. He thought it was quite evident from what the Chancellor had said, that the time had come when something had to be done. Our best authorities tell us that the outlook is serious, and that in twenty-five years we will be face to face with a timber famine. They imported £30,000,000 worth of timber per annum, and he thought it was really time they should try to produce some of that wood at home. They knew perfectly well that when they planted wood they had to wait 80 or 100 years for their return. Landlords had been accused of being niggardly in not planting woods enough in the past. He was not defending his own class from that accusation, but there were extenuating circumstances. The most extenuating circumstance of all was the chronic impecuniosity of the landlord class.

After all, they must remember that wood to be profitable now would require to have been planted 70 or 80 years ago. He pretty well remembered the conditions of 50 years ago. The landlord would not plant simply because there was no market then, and foreign wood was coming in in overwhelming cataracts. He remembered, too, the larch disease. Nobody ventured to plant larch 30 years ago. It was simply considered waste of time and money, so deadly was the disease. They planted wood, and what was the return? Three per cent.; and they had to wait eighty years for that! Was that good enough? Any landlord who planted at that time under all these drawbacks and difficulties ought to have his name enshrined in imperishable memory by the State.

Dr. Farquharson then proceeded to deal with the many pests which had to be contended with in growing trees. He remembered forty years ago there was not a single squirrel in Aberdeenshire. Things have greatly altered since, and he would have the squirrel exterminated altogether. Rabbits, too, were one of the greatest curses the forester had. Then came black game, roe deer, and, in the winter time, red deer. They had, also, parasitic disease to contend with.

FORESTRY AND UNEMPLOYMENT.

There had been a good deal of talk about the great advantage of forestry in the relief of unemployment. He was no great believer in getting the tag-rag and bobtail to help in forestry. It needed skilled labour, and he would have the small holders and crofters given employment in their slack seasons. That was the real way in which he thought forestry might be of service to the rural community. What about the State and forestry? He was not much of a believer in State interference. He thought private endeavour would be much better than attempts by the State. State aid meant State control, and fussy interference. The State might help in cases where the landed proprietor could not, or would not, have anything to do with it. The lecturer then proceeded to point out some of the drawbacks of the landed proprietors. Their system of rating was very much against planting, and he would have forestry relieved from local taxation.

An animated discussion followed Dr. Farquharson's address, in which Sir John Fleming, who is a member of the Departmental Committee on the Afforestation of Scotland, joined. Sir John said that, no doubt afforestation was in the air. When a question came to be a public question, as this had, they might be very certain that it was only a matter of a very short time until something practical resulted. Referring to the pending report of the Departmental Committee, he said it was a pity it had not been placed before the public ere now. In this report they had touched upon most of the matters discussed at that meeting, and they had made suggestions which he hoped would lead to a very great amelioration in regard to forestry. The report would shortly be out, and he was sure they would all be pleased with it. Dr. Farquharson seemed to think that the State should not tackle the subject of afforestation. That was very much what the report would say. They had recommended that all sorts of encouragements should be given to the private owner to go in for afforestation. At the same time, he thought there was a misconception abroad. It was not the case that forests were specially taxed. They were only taxed at the price of pasture land. The report made recommendations that would make it even easier than in the past in matters of that kind. Dr. Farquharson must be aware that, although State forestry might not be feasible here, it prevailed very largely in other countries. In Russia a very large proportion of the forests were under the State. They were treated on a proper system, put up by auction at upset price in blocks every year, and were well conserved and looked after.

Very cordial votes of thanks to all who had contributed closed a very instructive meeting.

Bristol Gardeners' Association.

A largely-attended monthly meeting was held at St. John's Parish Rooms, presided over by Dr. Shingleton Smith. The society having suffered a severe loss by the death of Mr. Francis Tagart, F.L.S., a vote of condolence and sympathy was passed to his family. The loss of Mr. Tagart is keenly felt, as he was a real friend to Bristol gardeners; he died in his 94th year.

Mr. Horne, of Cardiff, read a paper on "Winter-flowering Begonias," and gave a full description of the best varieties and the best way to grow them. The lecturer specially recommended the new hybrids, and said these would take the place of the Lorraine group before long. The best and easiest way of propagation is by leaf cuttings, which give the strongest and most bushy plants. Mr. Horne brought flowers of about twenty varieties, chiefly of the new hybrids.

For two dishes of apples Messrs. Scott, Springham, and T. Clarke won in the order given. Messrs. Springham and Jennings were awarded five points each in the point competition.

FORTHCOMING ENGAGEMENTS.

MONDAY, December 25.—Christmas Day.
TUESDAY, December 26.—Bank Holiday.
THURSDAY, December 28. — National Horticultural Society of France.
Manchester and North of England Orchid Society.

If in doubt as to Christmas and New Year gifts, send a postcard to Publisher, 148-9, Aldersgate Street, London, for the new complete Catalogue of Gardening Books. There is no more acceptable gift than a good book on some phase of Horticulture.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

CYPRIPEDIUM SAUNDERSIANUM. — L. G. W., Manchester: This hybrid is rarely found in cultivation, and it belongs to the group, or genus, known now as Phragmopedilum. It was raised at Enfield by Mr. Marshall, and appeared in 1886. If we remember rightly, the hybrid was distributed by Mr. Wm. Bull, of Chelsea. The parents are C. caudatum and C. Schlimi, the former being the seed-bearer. Doubtless it would do well under the same conditions as C. Sedeni, C. Schröderæ, C. conchiferum, and C. cardinale.

LAYERING ANDROSACE SARMENTOSA. —E. F. C., Newbury: A good plan is to place some gritty soil around the parent plant when the runner-like growths are being produced, and instead of pegging these latter down, place a stone on each stem.

CERTIFICATED CHRYSANTHEMUMS.— B. B., Newark: The three chrysanthemums you mention—Mrs. H. Weeks, Major Bonaffon, and Mons. Chenon de Léche—all received official recognition from the National Chrysanthemum Society's Floral Committee at a meeting held at the Royal Aquarium, Westminster, on Monday, November 11, 1895—sixteen years ago. The exhibitors were, respectively, Mr. H. Weeks, Thrumpton Hall, Derby; Mr. W. Mease, Downside, Leatherhead; and Mr. W. Wells, now of Merstham. The varieties are now seldom seen on the show board.

DIE-BACK IN GOOSEBERRIES.—S. H., Bath: "Die-back" is caused by a fungus that can hibernate in the host in the form of mycelium, or on the surface by means of sclerotia. The best means of getting rid of the disease are the prompt removal and burning of all dead bushes or dead branches in a plantation. As soon as the leaves of bushes show whitened margins, the bushes in the plantation generally should be examined, and any bush found with the main stem diseased should be grubbed up and burned. The prompt removal and burning of all dead (or dying) bushes, carried out for a few seasons, has proved more efficacious against this disease than spraying. It must not be forgotten that this fungus is capable of developing vigorously on dead parts of the bush. In nearly all cases—except in the comparatively rare ones where a plantation has been planted up with Botrytis-infested young bushes—the disease appears first either on single bushes scattered here and there through the plantation, or on all the bushes over a small patch of ground in the plantation, while the surrounding bushes are healthy. If the disease on its first appearance is dealt with summarily by the burning of all dead bushes and dead branches, there is no need to spray or to take any other remedial measure, since the disease soon completely disappears. Where the disease has been allowed to become severe and widespread, or where it is not in the power of the grower to remove entirely the source of the disease, spraying must be resorted to—in addition, of course, to the prompt burning of all dead bushes. A heavy spraying with a solution of copper sulphate (4lb. dissolved in 100 gallons of water) should be given just before the buds burst, with the object of destroying the tufts of Botrytis, care being taken to spray heavily the main stems of the bushes. The infection or premature falling off of the leaves may be prevented by spraying, directly the fruit is set, with Bordeaux mixture composed of 8lb. copper sulphate, 8lb. quicklime, and 100 gallons of water. In this spraying it is essential that the under-surface of the leaves should be sprayed as much as possible. No injury follows the application of Bordeaux mixture of this strength, and if the spraying be done at the time indicated, no spotting of the berries occurs. It may be noted finally, that any treatment which induces the bushes to make vigorous growth tends to stop the attacks of the fungus.

WINTER CUCUMBERS. — J. D. A., Epsom: The minimum night temperature should be 60 degrees, and there ought not to be any difficulty in maintaining this if the heating apparatus is ample, without producing that stuffiness in the atmosphere that results from few hot-water pipes and excessive forcing. Top-dressings should be given sparingly during the winter, as it is far better to allow a few roots to show through the soil than overload the border with rich material that cannot be readily assimilated at this season of the year. Liquid manure should also be given sparingly; it should be the colour of pale ale or weak tea, and be strained through a cloth before use, as then it will not clog the surface soil.

HYBRID GLADIOLI.—N. S., Chippenham: The strong likeness that exists between the Childsi and Nanceianus groups of gladioli is easily accounted for. M. Lemoine secured a race by crossing G. Saundersi with robust varieties of G. Lemoinei, and distributed it under the name of G. Nanceianus. Herr Max Leichtlin crossed G. Saundersi with a variety of G. Gandavensis at an even earlier date, and the resulting seedlings, after coming into the hands of a French firm, passed on to Messrs. Hallock, of New York, and from them, by purchase, to Mr. Childs. During this period a great deal of improvement had been obtained by selection, but none of the varieties had been distributed, consequently Mr. Childs put this race on the market as G. Childsi.

YELLOW-STEMMED WILLOW.—M. E., Chichester: The yellow-stemmed or yellow-barked willow (Salix vitellina), is a fine subject for the margin of a lake, stream, or island, and is of especial value for the colour effect it produces during winter. It must have abundance of moisture, and a mulching with manure or pond mud will materially assist it. To obtain the best colour effects, it is desirable to prune the plants hard back, quite near the ground, each early spring. The result is the production of strong, tall wands with clean, bright bark, that, after the fall of the leaf, shines brightly in the winter sunlight. If space permits, a good colony should be planted, as then the colour effect is the more striking.

RIHA'S CORELESS PEAR.—A correspondent (M. W., Huntingdon) writes asking whether any of our readers have ever grown Riha's Coreless Pear: and, if so, with what results. He also asks for information concerning its parentage. We cannot at the moment lay our hands upon information concerning the origin of this coreless pear, but if memory serves us rightly, it was distri-

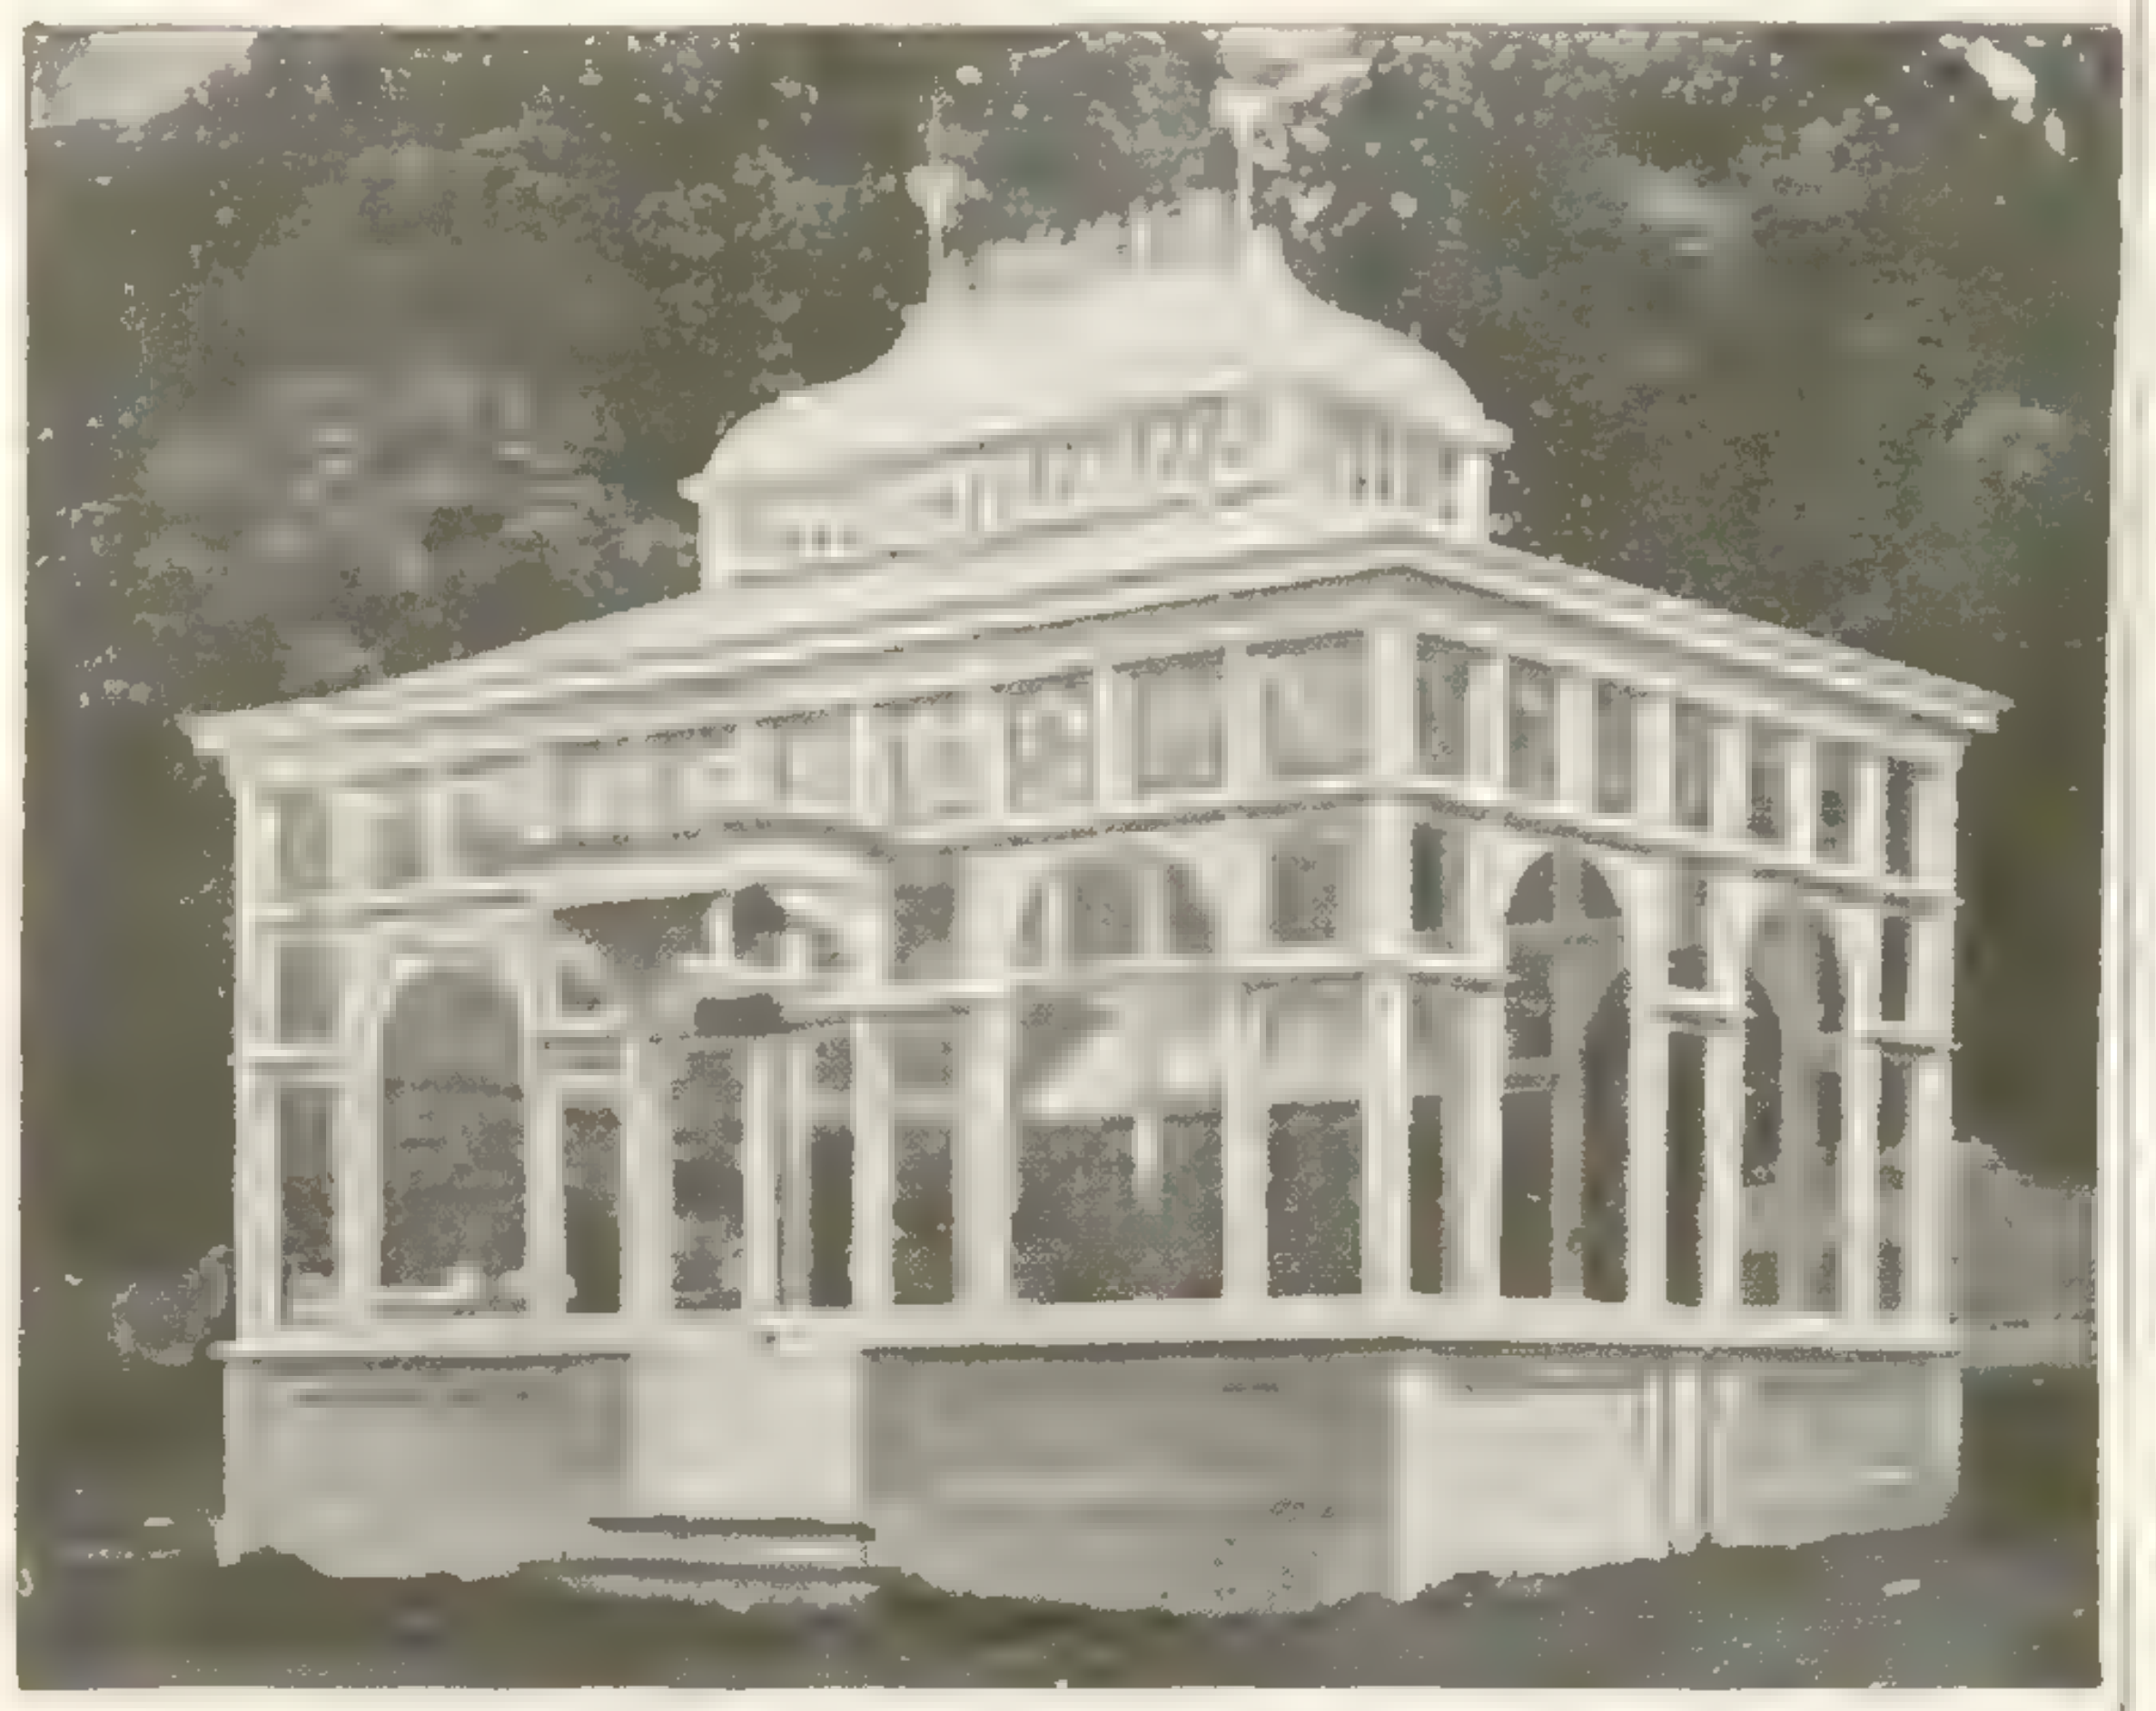
The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price 10/6. Sole proprietors and manufacturers, Robinson Bros., Ltd., West Bromwich.

PINE SPRAY SYRINGE (patent).

BOULTON & PAUL, LTD., HORTICULTURAL BUILDERS, Norwich.

ATTRACTIVE, PRACTICAL GLASSHOUSES.



Ladies and Gentlemen waited upon by appointment.

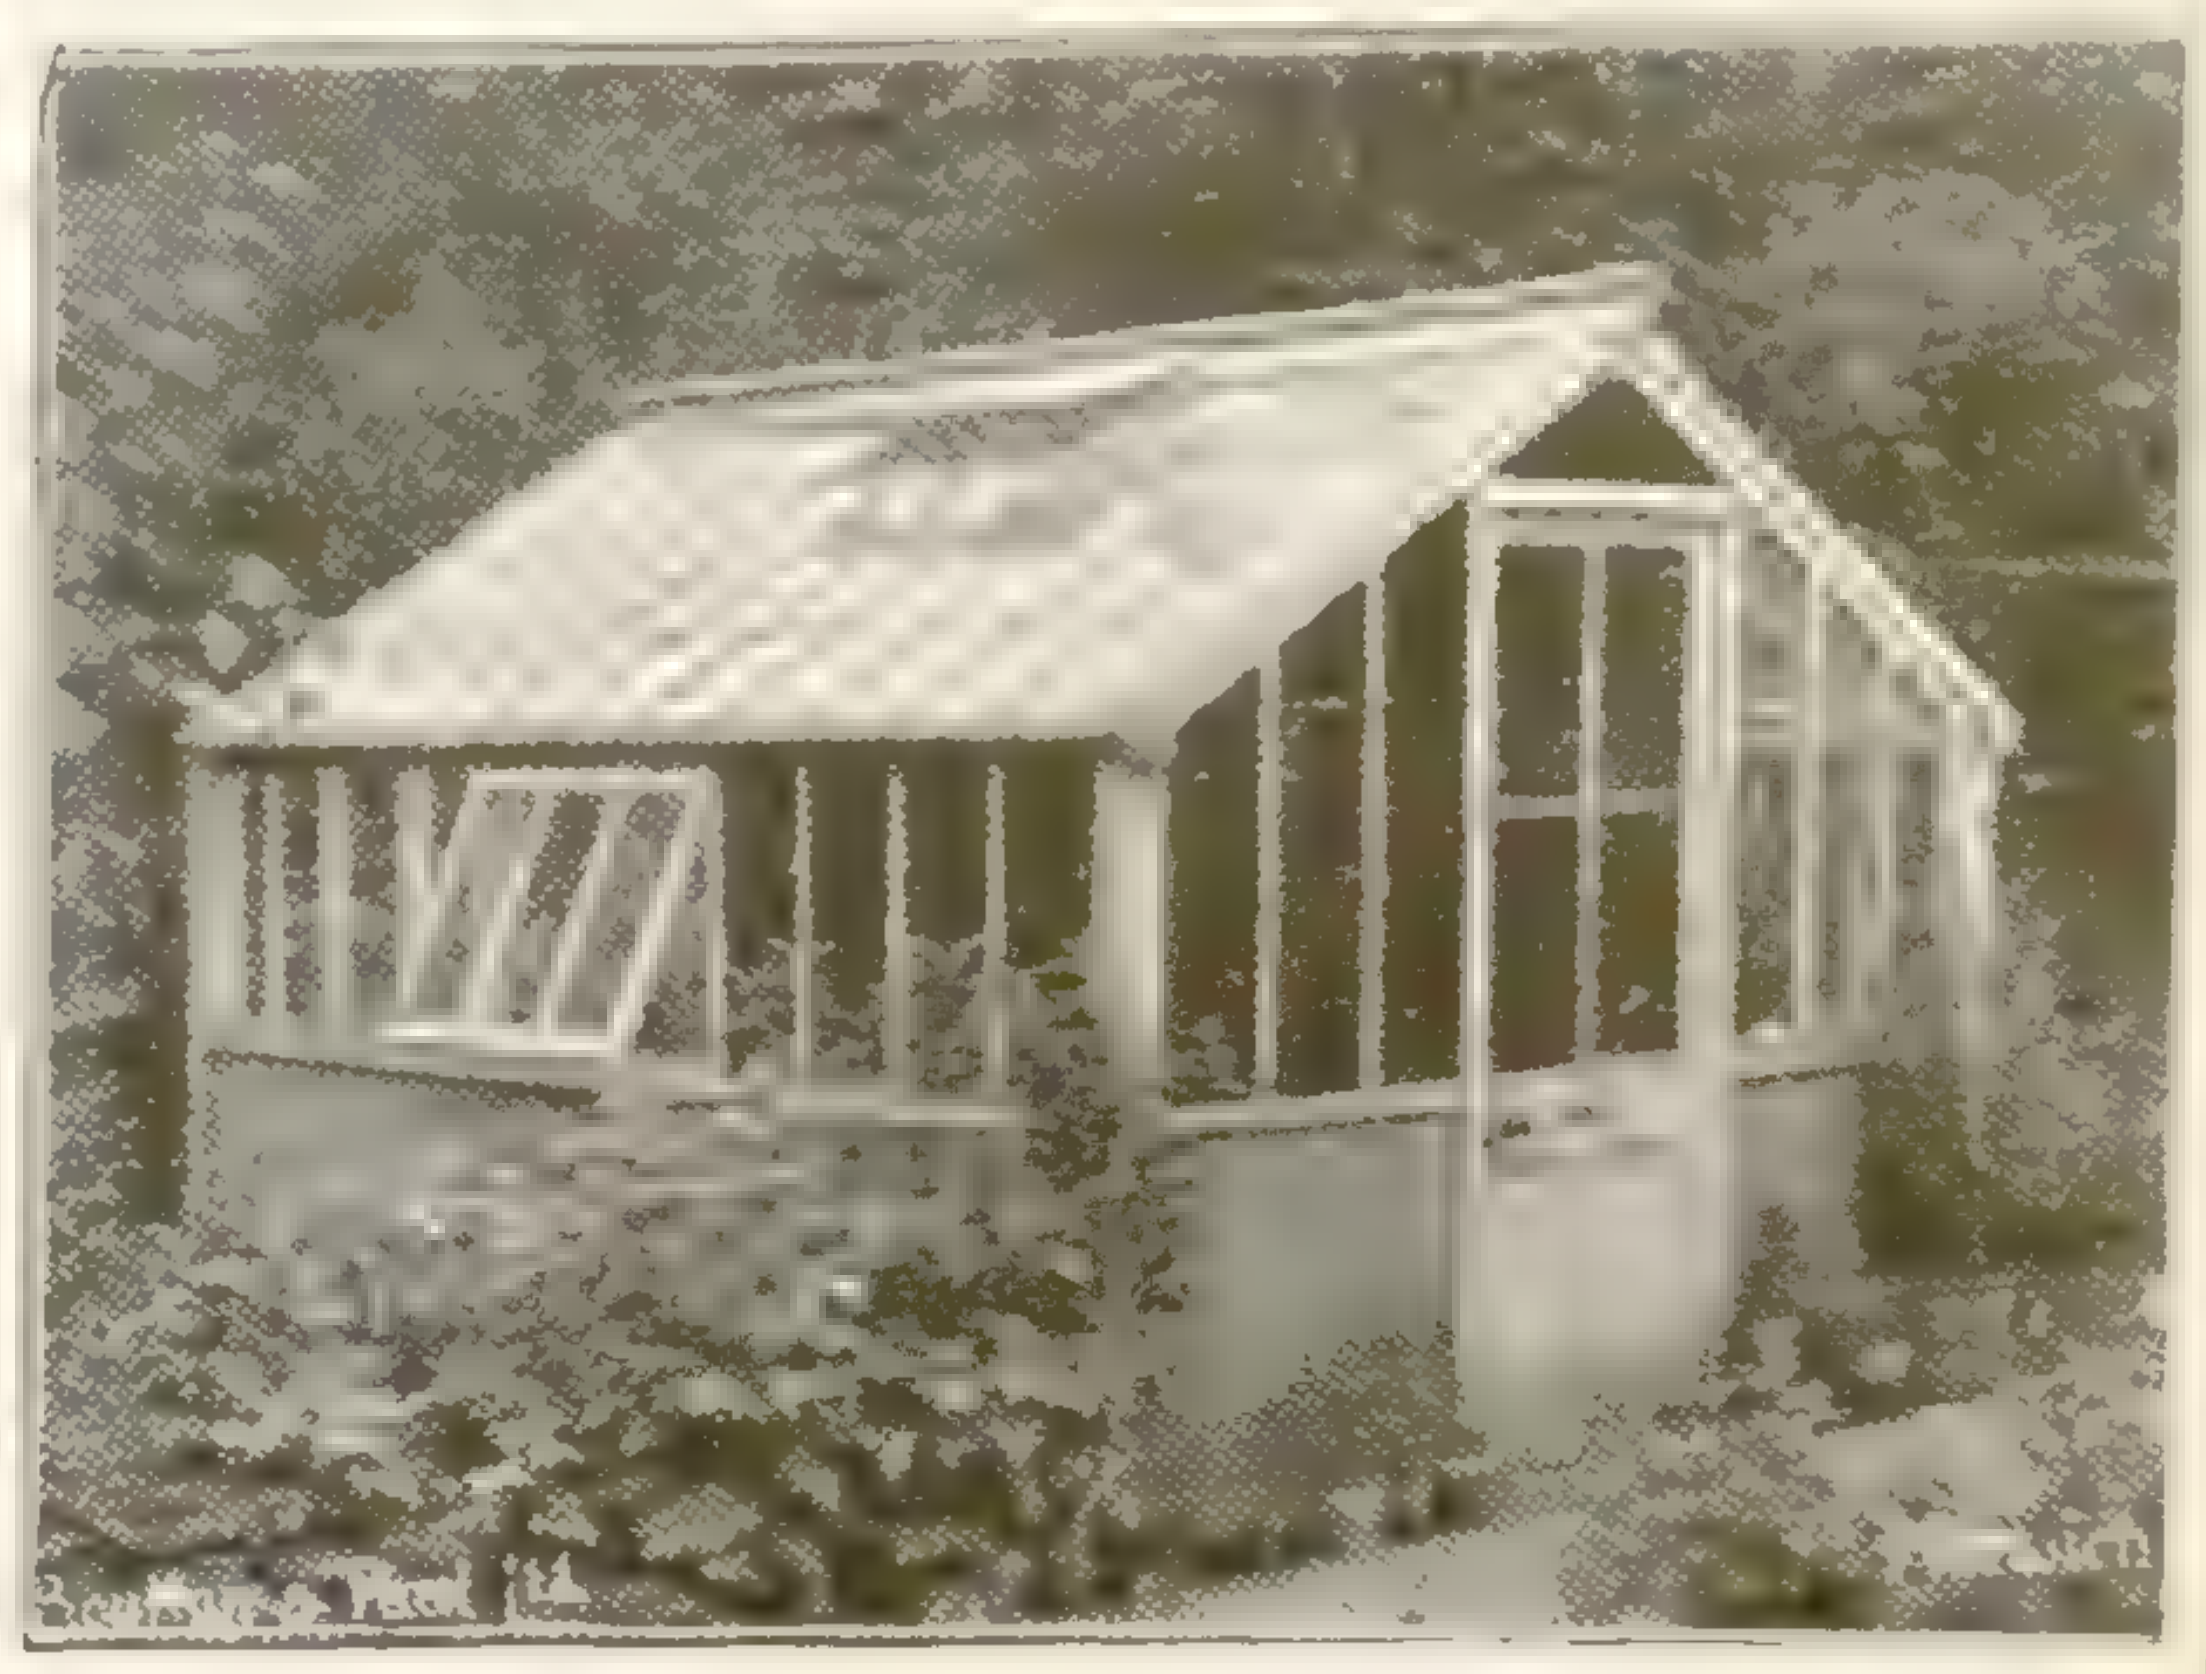
No. 77.—VIOLET FRAME, 6ft. by 4ft. Similar to No. 75, with Two Lights... **35/-**

SEND FOR ILLUSTRATED CATALOGUES.

Every part of these Houses is thoroughly well made, painted three coats. GLAZED AT OUR WORKS WITH 21oz. GLASS and CARRIAGE PAID.



No. 49A.—Span, 10ft. by 7ft. £11 10 0
No. 47A.—Lean-to, 10ft. by 7ft. £9 10 0

All parts are numbered ready for easy re-erection by any handy man.

buted about fifteen years ago, and we fancy Herr Leon Spathe was concerned in its distribution. Perhaps some of our readers can help us in this matter.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

N. W., Bristol.—Ipomœa Horsfalliæ.

T. A. L., Ripon.—Masdevallia Tovarensis.

M. E., Chichester.—The Yellow-barked Willow, Salix vitellina.

F. E. G., Worcester.—1, Chimonanthus fragrans; 2, Callicarpa purpurea.

C. N. F., Esher.—1, Cypripedium Hera Euryades; 2, C. Actæus; 3, Oncidium varicosum Rogersi.

P. P., Chelmsford.—1, Juniperus Sabina; 2, Cupressus macrocarpa; 3, C. torulosa; 4. C. Lawsoniana albo-spica.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate letter is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

D. V. B., Grantham.—1, Golden Noble; 2. New Hawthornden.

S. J., Hereford.—1, Vicar of Winkfield; 2. Catillac; 3, Warner's King.

C. L., Isle of Wight.—1, Newton Wonder; 2, Dumelow's Seedling; 3, Golden Russet; 4, not recognised; 5, Glou Morceau.

F. L. G., Cheltenham.—Probably Baumann's Red Winter Reinette, but the specimen was not a good one for identification.

OBITUARY.

◆

MRS. STEPHEN WALKER.

We learn with regret of the death, a few days ago, of Mrs. Stephen Walker, widow of the late Mr. Stephen Walker, of the firm of John Walker, Thame, Oxon. Mrs. S. Walker was in her 68th year.

BULBS.—A practical treatise on the cultivation of hardy, hothouse and greenhouse bulbous and tuberous rooted plants is "BULBS AND THEIR CULTIVATION," by T. W. Sanders, price 2s. 6d. net, or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

Situations Wanted.

GARDENER (Head Working).—Mr. COLLEDGE, Gardener to the Earl of Darnley, highly recommends F. BISHOP, as above; 4½ years as Foreman here. Cobham Hall Gardens, Gravesend, Kent.

GARDENER (Head Working), thoroughly experienced in all branches; excellent references; married; disengaged through establishment being given up. G. HALL, Hermitage Cottage, Minchinhampton, Glos.

GARDENER (Head Working) (Scotch) requires SITUATION where 2 or 3 are kept; 20 years' experience in all branches of gardening; 5 years present situation; married; age 36; 2 children; excellent testimonials. H. McCARTNEY, Sandye Place, Sandy, Beds.

GARDENER (Single-handed, or where help is given); 12 years' practical experience; 4 years in last situation; good references; single; age 36; abstainer. J. CHAPMAN, Ferry Hill, Chatteris, Cambs.

GARDENER (Head Working, where one or two kept); 10 years in present situation; 5 years as second; age 31; married when suited. A. GIBBS, The Gardens, Farrants, Bickley, Kent.

GARDENER (Head Working). — Mr. H. HEMSLEY, Rock Expert, Crawley, Sussex, would be pleased to highly recommend a thorough competent man in all branches of the profession: highest references; age [illegible]; married. Address as above.

HEAD WORKING, or Single-handed, abstainer; disengaged; age 36; one boy, 14½ years; life experience Inside and Out; excellent refs.; over 5 years last place; knowledge oil engine, electric light, and bees, will assist in house if required. J. OSMOND, Hickleys Cottage, Badshot Lea, Farnham, Surrey.

GARDENER (Head Working).—H. ESSAM can confidently recommend his Foreman to Lady or Gentleman requiring the services of a thoroughly practical and reliable Head Gardener; age 31; married when suited; excellent references. oses Hall, Gisburn, Clitheroe, Lancs. No circulars.

GARDENER (Head) seeks SITUATION where three or more are kept; practical experience in all branches; excellent references; age 31. Address, S. DOUGHTY, Overstone Park Gardens, Northants.

MODERN GLASSHOUSES

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

VOL. LIV.—No. 3,035. SATURDAY, DECEMBER 30, 1911.

THE GARDENERS' MAGAZINE.

NOTE OF THE WEEK.

The Past Year.

The year that is now rapidly drawing to a close has been an eventful one, both in relation to the community at large and to those who are engaged in horticultural pursuits; and, as is usually the case when events of outstanding importance follow each other in rapid succession, not all were such as to afford unqualified satisfaction. Fortunately, the least satisfactory of the events were not specially connected with horticulture, and therefore do not come within our purview in a retrospect of the past twelve months. The first event of importance, and, indeed, the greatest of the year, was the Coronation of the King and Queen in June, and the unbounded loyalty to which expression was given on this auspicious occasion in all parts of the British Empire, and the complete success of the various functions associated therewith, while affording immense satisfaction, gave a promise of what is hoped may prove a long and prosperous reign. It is of interest to recall the fact, because of the indication it gave of the trend of public opinion in relation to flowers, that this great event gave rise to a considerable discussion on the relative merits of several flowers as the national floral emblem. The discussion, we may assume, interested those who took part in it, but as it left matters precisely where they had been for several centuries it may now be allowed to pass with the expression of the opinion that there is no prospect of the Rose being disposed from the high position it has, in its relation to the State, so long occupied. In referring to the garden in its varied aspects, it must be said that it involved much additional work in its management, and gave rise to increased anxiety and some disappointments. There were compensating advantages, but the year was one through which but few of those who are immediately concerned with the garden would willingly go again. In many gardens there was a shortage of bush fruits owing to the damage done by spring frosts. The strawberry season was appreciably shortened owing to the intense heat and the drought, and in not a few instances that came under our notice the raspberry crop was practically a failure from the two last-named causes. Apples and plums, which may be described as the most important of the hardy fruits, were abundant, and pears and cherries were more plentiful than for some years past, but they were not satisfactory crops. Apples attained a higher degree of development than for a long period, and as Scotland shared to the full in the great heat that was experienced in other parts of the United Kingdom, these fruits attained a size and colour that was quite exceptional across the Border to the advantage of the autumn exhibitions, and the fruit store. It is a matter of common knowledge that no such complete failure of summer vegetables has occurred within the memory of the present generation of horticulturists. There have been long-continued droughts and reduced supplies, but there has not been a year in which for many weeks the market supplies of home-grown kinds have been practically limited to potatoes, vegetable marrows, and New Zealand spinach. The last-named was less affected by excessive heat and long-continued drought than any other vegetable grown for its leaves, and proved of much value. Having regard to the difficulties experienced in establishing breadths of Brussels sprouts and other winter vegetables, it is surprising the supplies are so good at the present time as is generally the case. On the other hand, we have had this year one of the finest crops of potatoes that has yet been lifted in this country, both yield and quality being quite exceptional. In the flower garden there have been some disappointments, and the most strenuous endeavours were necessary to maintain the majority of the subjects in a progressive state. In many gardens herbaceous plants failed to attain their full development, or to continue in bloom for so long a period as usual; roses failed to blossom so freely as in the majority of seasons, and sweet peas, which are now so largely grown for the supply of cut flowers for the adornment of the home were far below the average in bloom production, and in gardens where the plants had not been provided with a deep root run they collapsed at an early period, and rendered but small service either in contributing to the attraction of the garden or supplying cut flowers. Deep cultivation is always advantageous both to ornamental plants and useful crops, but in a dry summer such as that of the present year, its value cannot be over-estimated. The exhibitions held during the summer were more variable than usual; some were less extensive and attractive than in previous years, and not a few suffered financially from the high temperature that was experienced on the dates on which they were held. This point is of interest because of the prevalence of the belief that the weather cannot be too fine for a flower show, but this is a mistaken belief, as proved in so many instances that have come under our notice. It is essential to success that the weather be dry, and provided this be the case the number of visitors will be much larger with the thermometer at 70 degrees than at 80 degrees. It is gratifying to be able to record the fact that the exhibitions and meetings of the Royal Horticultural Society were, as a whole, highly successful. At the Temple Show there was a glorious display of the various plants and flowers available for exhibition in May, and the summer show at the Olympia was a great success horticulturally, but the financial results were hardly equal to expectations. The weather was intensely hot at the time, and the general public failed to take advantage of the opportunity they had for visiting the exhibition in the evening at a cheap rate. The show of British-grown fruit held in October was the most successful gathering of its kind held within recent years, the dis-

MR. W. B. GINGELL.

play of fruit being exceptionally good and the attendance of Fellows and other visitors much above the average. The high level of the fortnightly meetings was well maintained, and the crowded state of the Horticultural Hall on the occasion of the majority of them was a sufficient proof of their continued popularity. The special societies have, on the whole, had a successful year. The National Rose Society continued on its upward course, and completed its year's work with a larger balance to its credit and an increased membership. The National Sweet Pea Society also achieved much success, although the season was far from favourable to sweet peas. Of the National Chrysanthemum Society, Perpetual Carnation Society, National Dahlia Society, Midland Daffodil Society, Midland Carnation Society, and some other of the special societies, it may be said that they did excellent work in their several spheres of usefulness. The activities of those engaged in the improvement of the several classes of plants that contributes to the attractions and usefulness of the garden were in no way less pronounced than in past years. For an unquestionable proof of this we have only to turn to the lists of novelties that received awards in the course of the twelve months which form an important feature of the "Gardening Year Book" for 1912, which has just been published. Therein we find that some three hundred new introductions received awards, and that new garden flowers total 159, new orchids 106, and new plants other than orchids 73. The number of new orchids is of much interest as indicating the popularity enjoyed by these fascinating plants and the energy that is being brought to bear upon the development of new forms. In point of numbers chrysanthemums rank first among new garden flowers, roses come next, and carna- order. In counting up our gains and re- tions and dahlias follow closely in relative calling to mind the splendid work that has been accomplished during the year, we are reminded that we have lost several distinguished botanists and horticulturists who, in the course of their lives, did much for the advancement of botanical science and horticultural practice. Chief among the botanists whose deaths we have had to record were Colonel Beddome, who is best known for the work he accomplished as head of the Indian Forestry Department, and Sir Joseph Hooker who will be remembered as the most distinguished botanist of his day. The amateurs included Mr. W. E. Gumbleton and Mr. R. N. G. Baker, the first known for the active interest he evinced in rare plants, and the second famous as a grower and exhibitor of roses. Prominent among the names of the practical horticulturists who have passed away is that of Mr. James Douglas, who will long be remembered, not alone by florists, with whom he was closely associated, for his ability and integrity, and for the immense amount of good work he accomplished in the advancement of horticulture. The year which has passed, while containing much upon which we can look back with a strong sense of satisfaction, was beset with difficulties, and we trust in the interest of all concerned, with the garden and its management, that in the coming year the climatic conditions may be of a more normal character.

Mr. W. B. Gingell, the superintendent of the London County Council's very beautiful park at Dulwich, is a clever, but withal a modest, man, and it has not been easy to secure his portrait for publication. Mr. Gingell commenced his gardening career under his father, who was head gardener to General Hall, in Sussex, and he has very keen remembrances of his initiation into the art of gardening in 1868, as that year was a hot and dry one; the water supply gave out, and he had to assist in carting water nearly a mile, day after day, to keep the glass department and the flower and kitchen gardens supplied. In 1874 Mr. Gingell went to Cyfarthfa Castle, in South Wales, then a famous place, and where pineapples were grown by the thousand and grapes by the ton, the latter in eleven vineries, some of which were over 100ft. long. Subsequently he held various appointments at Shoreham Place, Wadhurst Park, Arle Court, Furze Down, Mentmore, and Blenheim Palace, and then became head gardener to the Earl of Harrowby, at Sandon Hall, Staffs. In 1890 he was appointed superintendent of Ravenscourt Park, Hammersmith, and this position he held with very great credit for twenty years, only giving it up on his transfer to the more important position he now occupies at Dulwich. This is a very bare record, but it is so because Mr. Gingell would not wish it to be otherwise.

Our First Issue in the New Year will be of special interest to our readers. It will contain articles devoted to such widely differing subjects as the Horticultural Education Movement, the Rose Season of 1912, New Orchids of 1911, A Famous Suffolk Garden, Revolution in Vegetable Culture, New Trees and Shrubs of 1911, Sweet Pea Progress, the Great International Horticultural Exhibition of 1912, and Forestry as a Profession. These will be contributed by well-known writers. The illustrations will be numerous and quite up to that high standard of reproduction with which our readers are familiar, and of which we are pardonably proud. With the issue of January 6 we shall publish the Gardeners' Magazine Almanack for 1912, attractively printed in colours, and giving the dates of the principal horticultural exhibitions for 1912. The Almanack will be of double-page size, and is published free of charge, therefore we urge our readers to see that they receive a copy with the first issue of the New Year.

A First Prize Railway Garden.—In the competition during the past year for the prizes offered by the Midland Railway Company for platform gardens, the premier award was made to the garden at Five Ways Station, Birmingham. The display of flowers was highly meritorious throughout the summer months, and the success achieved is all the more remarkable from the fact that the garden is near the mouth of a tunnel from which sulphurous fumes are constantly being emitted.

A Beauty Spot for Shoreditch.—We have on a previous occasion told the story of how Sir Robert Geffery, a wealthy member of the Ironmongers' Company, who died early in the fifteenth century, left a sum of money for the provision of almshouses in or near London. The charity was left in the management of the Company, and eventually a site was selected in Shoreditch and here, to the designs of Sir Christopher Wren, a quadrangular building, one-storied, accommodating about fifty pensioners, was built. This building, known as Ironmongers' Almshouses, will be familiar to all who have passed down Kingsland Road, because of the simple dignity of the building, and also because of the trees, grass plots, and flower beds in front. A few years ago the Ironmongers' Company wished to sell the site to the Peabody Trustees, and build almshouses out in the suburbs; several public bodies opposed the sale, as also did the Charity Commissioners, but by means of an old dormant Chancery suit the Company presently obtained permission to sell. The loss of the almshouses and garden seemed certain, but as a result of heroic efforts to secure the site for the public good, the Peabody Trustees offered to surrender their purchase, the London County Council offered £16,000, and the Shoreditch Borough Council £6,000, towards the £24,000 needed to place Sir R. Geffery's charity on a safe settlement. A local committee, after eighteen months' hard work, secured the remaining amount, the London County Council promised to take charge of the garden, and so now the old-world beauty spot will be preserved to Shoreditch, and the Metropolis will keep in its midst a bit of Wren's London.

Potato Crop, 1911. — The crop of potatoes harvested in the course of the year now drawing to a close is somewhat larger than in 1910. The area under potatoes in Great Britain was 571,808 acres, and the estimated yield 3,830,218 tons, these figures representing an increase in the area of upwards of 30,000 acres, and in the crop of about 350,000 tons, as compared with last year. The average estimated yield per acre was 6.70 tons, as compared with 6.44 tons in 1910 and 6.08 tons the average of the ten years 1901-10. The quality of the potatoes, as so well known, is exceptionally high this year.

Colley Hill, Reigate.—With reference to the effort that is being made to obtain the necessary funds to purchase Colley Hill, Reigate, and to preserve it for public use, Mr. G. H. Hamer, secretary to the National Trust, writes: "May I call the attention of your readers to the actual state of affairs? The sum required to complete the purchase is £7,700, and of this amount some £2,000 has been actually given or promised. It is, therefore, clear that a great effort must be made if Colley Hill is to be saved, for the option of purchase expires in February next. A Shilling Fund has recently been instituted in Redhill and Reigate, and the widespread response to this appeal shows that the inhabitants of the locality are keenly interested in the preservation of this open space. The National Trust, while it warmly welcomes the support of subscribers of small sums, sincerely hopes that larger amounts will be forthcoming in the near future. Subscriptions may be sent to me at 25, Victoria Street, S.W., or paid direct into the Reigate branch of the London County and Westminster Bank."

Soil Sterilisation Lecture.—With reference to Mr. G. Harris's communication on this subject, which appeared in our issue of the 23rd inst., the Rev. J. Bernard Hall, secretary of the North of England Horticultural Society, writes: Will Mr. George Harris allow me to draw his attention to an omission on his part? At the Northern Fruit Congress at Newcastle he lay low like a torpedo-boat and then in the discussion fired off a torpedo at the battleship opposed to him. As a matter of fact, the torpedo had no explosive head, and, although it hit the battleship, yet he quickly drew off and steamed away before any of the lecturers had received the command to fire. I reckon that if he had only stayed to receive the fire of the 12in. guns, he would have been blown to pieces. It's all very well getting in your shot, but is it the game, is it sporting, to clear off and then write to the papers? If science is "organised common sense," or, as was suggested at a Leeds meeting some time ago, "distilled common sense," surely such exponents of science (and, if I may add, in Mr. Chittenden's case, applied and practical science) were worth listening to, when they got up to answer the questions put to them. Mr. George Harris has our sympathy, and the lectures were arranged to solve his troubles, but in future he must not "run away to fight another day." Intensive culture is bringing its own special troubles, but we have good men and true to give advice that is both truly scientific and thoroughly practical, if you'll wait and listen to their answers.

The Gardening Year Book for 1912, which has just been published, possesses so high a degree of value as a work of reference on gardening that all who are more or less concerned with the garden and its management should at once obtain a copy and place it where it can be readily consulted. Therein they will find an ample diary, with a code of garden management for the year conveniently arranged under the several months. Then follow lists of the new plants, orchids, garden flowers, fruits and vegetables that obtained recognition during the past year. Of special importance are the sections wherein concise notes on the cultivation of annuals and biennials, hardy perennials, conservatory and greenhouse plants, hardy and other bulbs, hardy fruits, and vegetables, are given, and the finest varieties in the several classes pointed out. In addition to other cultural matters, and chapters on insect and fungoid enemies, there are directories of the public parks and gardens, and the botanical and horticultural societies of the United Kingdom. The work is fully illustrated and is a practical guide for the whole year. It is a splendid shilling's worth. It may be obtained from all booksellers, or post free, price 1s. 3d., from the publishers, 148 and 149, Aldersgate Street, London, E.C.

Gardening for Soldiers.—By a special decree of the Austrian War Office fruit and vegetable gardens are to be formed on waste ground around barracks, drill yards, rifle ranges, etc. The soldiers will be encouraged to cultivate these in their spare time, and any profits derived from them will be divided among the men. It is hoped that the plan will not only provide the soldiers with a profitable and interesting occupation in their spare time, but will enable them to learn much that will be an advantage to them on their return to civil life. A similar plan has proved most successful in Germany.

Variation in Foxgloves.—Mr. N. C. Macnamara gives some interesting particulars of the variation in the plants raised from a packet of seeds of the foxglove (Digitalis purpurea). The seed was sown in 1906, and in June of the following year fifty-four plants raised from the sowing were planted in a shrubbery of fir trees with an undergrowth of laurels. Of these fifty-one were normal, but the three remaining plants were sports. In the first of the sports the flowers of the lower half of the stem possessed only a bifid upper petal and seven stamens united at their bases. The flowers of the upper part of the spike were normal. In the second, which was well grown, and attained a height of fifty-four inches, the flowers had throughout the whole length of the spike a bifid upper petal, seven stamens, and style. The upper part of this spike was isolated: it produced abundant self-fertilised seed. The third sport had a spike which reached a height of sixty inches, and from base to apex the flowers consisted of nine stamens and a style, with no vestige of petals. In Mr. Macnamara's opinion, a certain number of the foxglove seeds sown in the year 1906 contained elements in a condition such as that described by de Vries as being "impressed by an impulsive mutability," for some of the flowers produced by these seeds were sports. Seeds from these sports produced their like in 1909; and, further, these latter plants produced some terminal flowers totally differing in character from the parent sport from which they were derived. Seeds from these terminal flowers produced their like in the year 1911; so that there are now two different strains of foxglove plants produced from the seeds sown in 1906, and these strains have been produced from self-fertilised flowers, that is, from flowers carefully protected from insects or other means of cross-fertilisation.

Trials of New Roses at Bagatelle.—We are informed by M. J. Forestier, the Conservator of Promenades of Paris, that a trial of new roses will take place in the Bagatelle rosery, during 1912 and 1913, as in previous years. These new roses are contributed by the raisers, and we are requested to state for the information of raisers who have not previously sent roses for trial, that as far as possible the plants should have been grown in pots, that at least five plants of each variety must be sent to reach the rosery before April 15, 1912, and that if special treatment is desired, an intimation thereof must be sent with the roses. These, we are informed, will be planted in the beds in the rosery soon after their arrival, and remain therein until the month of October of the second year, to give the members of the jury an opportunity of having them under observation during two seasons, and thus be in a position to determine their relative merits both as regards flower production and habit of growth. The parcels containing the roses should be addressed to "Monsieur de Conservateur des Promenades de Paris (Roseraie de Bagatelle, au Bois de Boulogne, à Paris) en gare de Neuilly-Port-Maillot-Paris."

The British Gardeners' Association. A meeting of this association will be held on Friday, January 5, 1912, at 7.30 p.m. in the Technical Institute, Altrincham, Cheshire, when an address on the "Advantages of Joining the B.G.A." will be given by Mr. J. Weathers, general secretary. All gardeners in Altrincham and district are invited to attend.

Gardeners' Social Meeting at Kew.—The fifteenth annual social meeting of the gardeners in the Royal Gardens will be held at the Boat House, Kew, on Friday, January 12, 1912, commencing at 7 p.m. All past Kewites are cordially invited to attend, and it is hoped that past Kewites who are in or around London on that date will make an effort to be present if possible. We are asked to state that it will greatly facilitate the arrangements if those who intend being present will notify their intention not later than January 4 to the Hon. Secretary, Mr. G. W. Butcher, 34, Alexandra Road, Richmond, Surrey.

Sweet Peas for Garden Decoration.—In view of the near approach of the season for purchasing seeds it is interesting to notice that the Royal Horticultural Society's Floral Committee have Highly Commended the following sweet peas for garden decoration, after the consideration of about seventy varieties grown at Wisley in 1911: Aurora Spencer, Princess Victoria, Ivanhoe, Elsie Herbert, Dorothy Eckford, Gladys Unwin, Isobel Malcolm, Mrs. Collier, Lady Althorp, Asta Ohn, Etta Dyke, Elfrida Pearson, Apple Blossom Spencer, Tennant Spencer, Dobbies' Sunproof Crimson, and Countess Spencer.

NEW WAYS OF GROWING PERENNIALS.

The ubiquitous herbaceous border involves frequent work, thinning out being necessary as the vigorous plants develop. In a small garden a better effect can be gained from herbaceous beds, which are replanted every second year. A circle of six feet in diameter may contain a good combination of perennials, a group of three vesse and carmine phloxes in the middle, a ring of Madonna lilies, or giant white single columbines, then a row of mingled crimson, pink, and white hybrid pyrethrums, with a double edging of pansies and pinks. Another suitable combination would consist of white phlox, Oriental poppies, Lychnis Haageana, lemon carnations, and gold and white violas.

A giant square or oblong bed, on a lawn, looks well filled by irregular groups of perennials, just as the herbaceous border is usually arranged; this enables a great number of dwarf subjects to constitute the marginal row, which aids both in the attainment of companion-colour shows and of a succession of blossom. The tallest plants must occupy the middle space, medium growers coming next, then plants of about a foot in height, finally the low ones, such as aubrietias, alyssums, saxifrages, Geranium cinereum, Bellis perennis, Arabis variegata, violas of best habit, pinks, polyanthuses, primroses, and Viola cornuta.

An original scheme that involves some initial labour is to create a raised bed, in tiers, for the cultivation of the best species of perennials. Several barrow-loads of loam, mixed with manure, leaf-mould, vegetable ash, and brick rubble, with road-sand if the ground is by nature wet and heavy, must be thrown on to the square or oblong plot. The next proceeding must be to level two or more feet as an edging, then insert strips of wood at the back of this, forming a support for another levelled portion several inches higher than the first. This work can be repeated until the centre of the bed is almost reached, the result being a series of tiers. If the space is large, the middle height will be considerable; in a smaller space the depth of the wooden bars may be greater, so as to obtain a better height. When perennials are skilfully arranged in such a bed the effect is very beautiful, the plants being shown off to perfect advantage. Chrysanthemums, Japanese anemones, the modern phloxes of dwarf habit and giant trusses, Coreopsis grandiflora, hybrid pyrethrums, Campanula latifolia, Campanula persicifolia, chelones, heucheras, Lychnis chalcedonica, Lychnis Haageana, Oriental poppies, pæonies, pentstemons, the lesser Michaelmas daisies, achilleas, columbines, centaureas, clove carnations, sweet williams of giant varieties, the splendidly brilliant Scotch striped antirrhinums, large-blooming pinks, double arabis, mossy saxifrages are especially suitable.

A sufficiently large round or oval bed will give an admirable display thus constructed and filled, a high mound of blossom being the result, but the work of filling the wooden strip supports is, naturally, more difficult; probably a narrow strip of very fine-meshed wire netting would suffice to hold the soil in, however, and could be easily bent into shape.

Perennials in tubs and large pots are not sufficiently cultivated. They make handsome effects when placed at summer-house entrances, outside porches, or on paved walks. A really excellent scheme is to grow them for ranging outside the walls of the spanroof greenhouse, where a border bed is seldom desirable. To safeguard pot plants of hardy species during the worst winters they can be sunk in cinder-beds to the rims, and a mulch of spent manure laid over. These cinder-beds can be made upon gravel, stone, or any waste land. Pots of cut-down perennials can also occupy frames or pits may be dug out in the open to receive them, and sacks or cocoanut-fibre refuse, bracken, dried heather, or gorse boughs, will sufficiently protect the plants then. Delphinium formosum is very attractive as a pot specimen. Madonna lilies, pink Japanese anemones, Chrysanthemum maximum, Britannia, or King Edward, the Plume poppy, Bocconia cordata, phloxes, large-flowering Michaelmas daisies, Scabiosa caucasica alba, prove charming.

For shady portions of gardens a supply of suitable tub-grown perennials can be specially recommended, as offering floral beauty where none could otherwise be. As soon as the florescence fails, or the plants begin to suffer for want of light and warmth, they should be removed to a sunny place. Then there are shade-enduring subjects of considerable beauty, notably white foxgloves, herbaceous phloxes, day lilies, golden rods, shrubby hypericums, and the tall Pyrethrum uliginosum. These will not fail to bloom freely. M. H.

APPLE COX'S ORANGE PIPPIN.

My experience with this apple does not coincide with that of Mr. Garner. While obtaining nice crops of fair fruit, I have much trouble with canker in the branches, and there is a general check to that freedom of growth we like to see in apple trees. Cox's Orange Pippin is an easy apple to grow in soil that is not heavy, wet, cold, and retentive of moisture; a well-drained loam is what this apple revels in, and this we all have not. Here the soil is heavy, closely approaching clay, but not actually clay. The subsoil is a hard pan of stiff material, much mixed with huge flints, quite an undrained base, and in this the roots do not find a congenial rooting medium. I may be told the roots have no business there. That may be so. In such a soil it is difficult to keep the roots in the right place.

This has been an exceptionally good season for this apple in an uncongenial soil; the trees have made quite good growth, with clean shoots, showing not the slightest sign of canker in the current growth, whereas in a bad season the young shoots decay in the autumn so much as to necessitate pruning them entirely away. This is caused by an excess of moisture at the roots, rendering the subsoil so cold as to cause a check to the proper maturation of growth. Under such conditions the growing of Cox's Orange Pippin apple is not worth the trouble, eventually ending in waste of space and a loss of time in establishing trees of a more desirable character. E. M.

Rhododendron Shilsoni.—It was recently advised in THE GARDENERS' MAGAZINE, page 286, to plant this rhododendron in bold groups of a dozen or more, but to many the cost would prove to be an important obstacle. The lowest catalogue price that I can find for this beautiful rhododendron is seven shillings and sixpence each. Plants at this price would, of course be small ones, and it is questionable if specimens, to be quickly effective, could be obtained at less than a guinea each. Furthermore, the stock, except small plants, is in most cases so limited that few groups such as that referred to would be possible. The propagation and growth during their earlier stages of these rhododendrons is by no means rapid, hence they always realise good prices.—W. T.

CLEMATIS INDIVISA.

I am rather surprised that this handsome greenhouse trailer is not more extensively grown than it is—at least, to my knowledge. I believe more plants are cultivated in northern than southern gardens. In one garden on the north-west coast I had charge of some houses in which this variety was very successfully grown. The position was certainly not an ideal one, as the greenhouse had been excluded from much sunshine through a more recently-erected building, but the branches were covered with the creamy-white flowers in spring time and looked very handsome trained on wires immediately above the pathway; the extreme ends of the shoots were allowed to depend gracefully from the wires.

In small houses, and where there is not much space to spare for making up borders, the plants will do very well in large flower pots, if top-dressed annually and fed judiciously. Light, fibrous loam two parts, leaf-soil one part, and peat and sand one part, form a very good compost for the plants. Too often such climbers are planted in sour soil under the stage, and then cultivators wonder why they fail. It is best to keep both pots and main stems exposed to the full light. G. B.

DWARF ŒNOTHERAS.

The dwarf and trailing species of the evening primroses provide a welcome addition to the list of plants suitable for rock garden cultivation. They are easily grown, providing a fairly rich soil is afforded them, and the species with trailing habit should be planted where the growth can hang over a ledge of rock. In the cool of the evening the large blossoms are highly appreciated, as some of them are deliciously scented.

Œ. marginata (or eximia) is undoubtedly one of the best; it has large white blossoms, measuring from four to five inches across. Its growths usually die back in the winter and shoots appears in spring, which flower continually during the summer. Œ. macrocarpa, like the preceding, has a trailing habit, but with large yellow flowers, and requires a warm position. It is a beautiful species, well deserving a prominent place. Œ. speciosa rosea has rose-coloured blossoms, and when planted where its slender growths can hang over a stone, is very effective.

Œ. taraxacifolia has flowers that are white when first they open, but assume a pinkish tinge with age. When planted in cold damp soils, the plants often die off during the winter, but when given a warm position in light soils, they will pass through the winter safely. Œ. pumila is the smallest species, growing only about four inches high, and bearing tiny yellow flowers. Œ. Youngi, Œ. Fraseri, and Œ. Pilgrimi are of upright growth, reaching the height of about twelve or fifteen inches, and all bear yellow flowers.

Regarding their propagation, the three last-named species are increased by root division, either in early autumn or spring. They should be carefully lifted, and divided by splitting the woody part in the centre of the clump, otherwise the side shoots will break off without any roots. Œ. macrocarpa, Œ. marginata, and Œ. speciosa rosea should be propagated by cuttings, which will root freely if taken in the early part of the autumn, inserted in sandy soil, and kept close in a cold frame.

In dealing with Œ. taraxacifolia the simplest method to adopt is to raise a stock from seed which should be sown in April or May, in pots or pans, filled with light sandy soil, and placed in a cold frame. When the seedlings are large enough to handle, they should be transplanted into seed boxes, eventually potting them up. Plants treated in this manner will usually flower during the following year.

Gnaton Gardens. E. C. POOLEY.

CLEARING UP FLOWER BORDERS.

Herbaceous borders will now require cleaning and putting straight for the winter. If there is no necessity for lifting and dividing the plants, the border should be given a top-dressing of decayed manure. Old hotbed material answers very well for this purpose, providing it is sufficiently rotted to prevent it blowing about. In dealing with borders, where the plants have become overcrowded, the work of thinning should be taken in hand as early as possible. This operation requires skilful handling, otherwise there will be great confusion, and only those subjects which actually are in need of lifting and dividing should be touched. It is quite a mistake to dig up every plant the border contains (and this is frequently done), for there are many plants which have a strong dislike to being disturbed. Among these may be mentioned Lilium candidum, eremurus, incarvillea, and heuchera, all which should be allowed to remain untouched, unless it is absolutely necessary to move them. It is quite safe to handle such plants as Michaelmas daisies, phloxes, helianthuses, heleniums, aconitums, solidagos, etc., and these can be lifted, divided, and replanted to advantage if anyway overcrowded. It is rather late in the season to attempt to disturb delphiniums or pæonies, but if this is necessary, it must be carefully carried out. If the border is a large one, rearranging should be carried out in sections, dividing it into suitable lengths, so that the plants may not remain out of the ground long. Each subject should be carefully placed on one side by itself and covered with mats to protect the roots from any ill effects which might be caused by the weather. When preparing the ground for replanting it should be deeply dug and enriched with decayed manure, bearing in mind the fact that the plants are to remain where planted for two or three seasons, and that many are gross feeders. When splitting up the old clumps, the outside portions should be selected for replanting, and the centres thrown away. The growths are much stronger on the outside than in the middle, and produce vigorous plants in a short time. When planting is completed, the surface of the border should be top-dressed, as advised, where the plants are not disturbed.

E. C. POOLEY.

Anthurium splendidum.—With reference to the note by "W. T." in the GARDENERS' MAGAZINE of December 16 (page 940), on this handsome species, I am afraid I cannot enlighten him as to whether it is still in cultivation. I myself have not seen it for some years. When penning my article, I had in mind several fine healthy plants of the species that were under my care nearly two decades ago, when I had charge of what was then considered one of the best representative private collections of stove plants in the country. I well remember the plants were purchased from Mr. William Bull, at Chelsea, and that we grew them well in one of the stoves among other choice tropical plants requiring similar treatment. All the anthuriums were particularly well grown, and some of the specimens remarkable for their foliage alone were in tubs 3ft. in diameter. A high temperature and humid atmosphere were kept up, and the noble proportions of the anthusiums indicated that they were perfectly at home.—H. T. MARTIN.

THE DECLINE OF THE BIG CHRYSANTHEMUM.

Another season's experience emphasises the feeling created last year that the interest in large chrysanthemum blooms is gradually diminishing. The enthusiasm felt in the shows themselves, even by interested cultivators, is nothing as compared to that of a decade ago. To many others, as well as myself, this is regrettable; even the most enthusiastic person is forced to admit that chrysanthemum shows do not create the interest they did some time ago. No doubt there are many reasons for this lack of interest and enthusiasm, but whether we shall all agree as to the true cause and the need for or creation of a revival is another matter.

Visiting many shows and reading the reports of others, even the most ardent supporter of the flower, whether he be financially interested or merely an admirer, cannot but realise the truth of the assertion. Naturally our thoughts turn to the so-called parent society—the National Chrysanthemum Society—to see how the November display was affected. Taking the leading class for Japanese blooms, forty-eight distinct, there were but two competitors! Writing from memory, as many as a dozen have taken part in the same competition a few seasons ago. Even for twenty-four blooms, there were but six entrants, and I have assisted in judging this class when there were twenty-six. One more example, what is known as the great vase class, for twelve varieties, three blooms of each, this produced but two exhibitors. When we find such a poor response to the schedule invitation of the leading society one is forced to the conclusion that there is a considerable lack of enthusiasm. On the other hand, we find that trade exhibits are finer and more numerous than ever, with the one exception, perhaps, that they do not contain such a wealth of new varieties in the many sections they used to do.

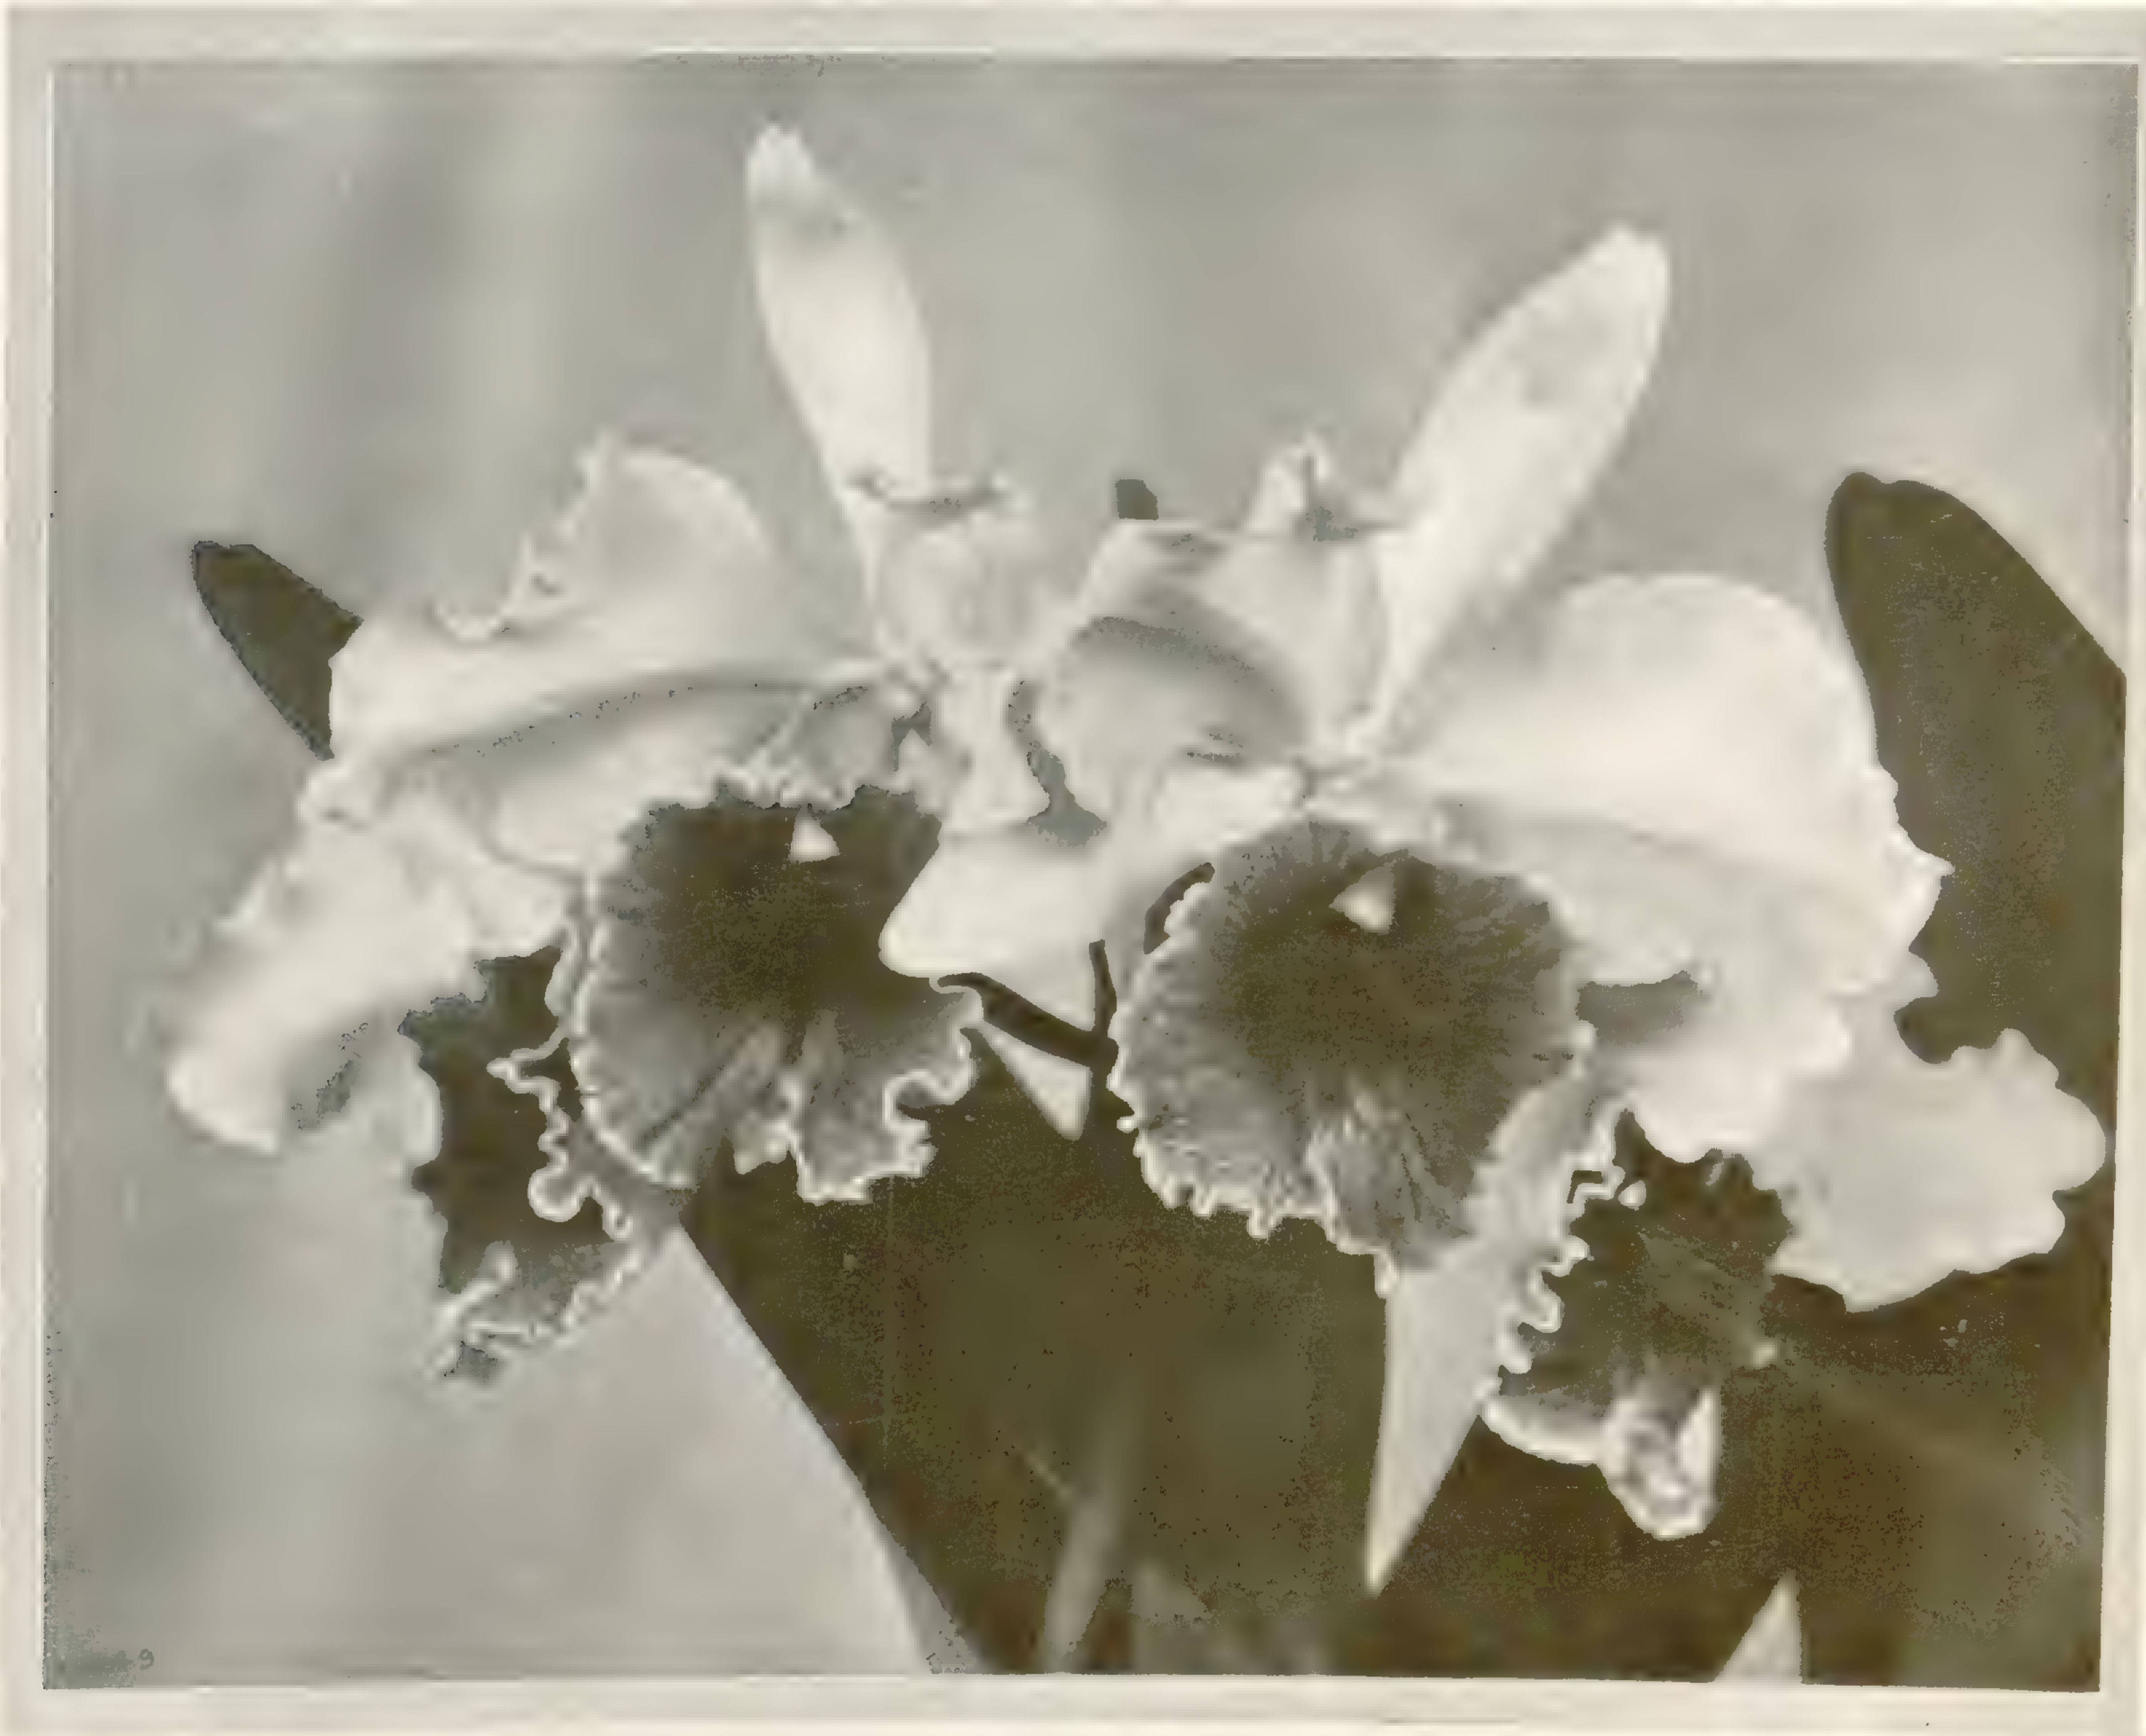
One is forced to the conclusion that some of the meetings are held too early in the season to admit of many of the varieties being fully developed, and especially does this apply to the incurved, anemone-flowered, and reflexed types of flower. We must not forget, too, how the shows must suffer from the absence of such exhibitors as Messrs. Vallis, Bible, Hall, Nicoll, Higgs, and Jefferies. This year we missed, especially, Messrs. Drake, Leck, and Stevenson from our English meetings, the latter only temporarily, though, we hope, and now comes the announcement that Mr. Mease has at last given up, although loth to do so, and I am sure no exhibitor will be more missed with regret.

Autumn shows sadly miss such an army of exhibitors, and there may be more. Unfortunately, too, for the flower, these tried exponents are not easily replaced; we do not see their gaps filled by new men.

Now what are the causes of the decline in big blooms at the shows? That is the point I am anxious to elucidate. In the first place, there are not nearly so many large blooms produced, either for competition or private use; ladies have tired of the monotony of even the Japanese section, brilliant though they are in so many ways. The cost of cultivation has much to do with the reason in many gardens. The increasing cost of the general upkeep of gardens weighs heavily on some shoulders, and as large blooms of chrysanthemums are purely a luxury, they are one of the first things to be cut out. The increase in, the utility of, and the general admiration for winter-flowering carnations has also had its effect on large chrysanthemums, and the latter have had to make room for the former in no uncertain manner. Single-flowered chrysanthemums have leaped quickly into public favour, and their merits as decorative flowers have become so widely appreciated now that the colours are very varied. Moreover, considering the ease with which the flowers can be grown, and the quantity of blossom obtainable in a minimum of space, the section deservedly occupies a commanding position.

The great range, too, now obtainable in early out-of-door chrysanthemums, coupled with the open favourable early autumn weather, so prolongs the flowering season that indoor chrysanthemums are not so eagerly sought after as they were when the Desgrange family was the only type of out-door-flowering varieties. Under glass, too, we have such a plethora of varieties grown purely for decoration, of such types as Soliel d'Octobre, Niveus, and the later sorts, that less space is now given up to the large Japanese blooms; varieties are now grown that produce from twenty to thirty fair-sized blooms on each plant, as compared with the three huge blossoms and sometimes but two, on one plant.

I cannot but think that the reduction of

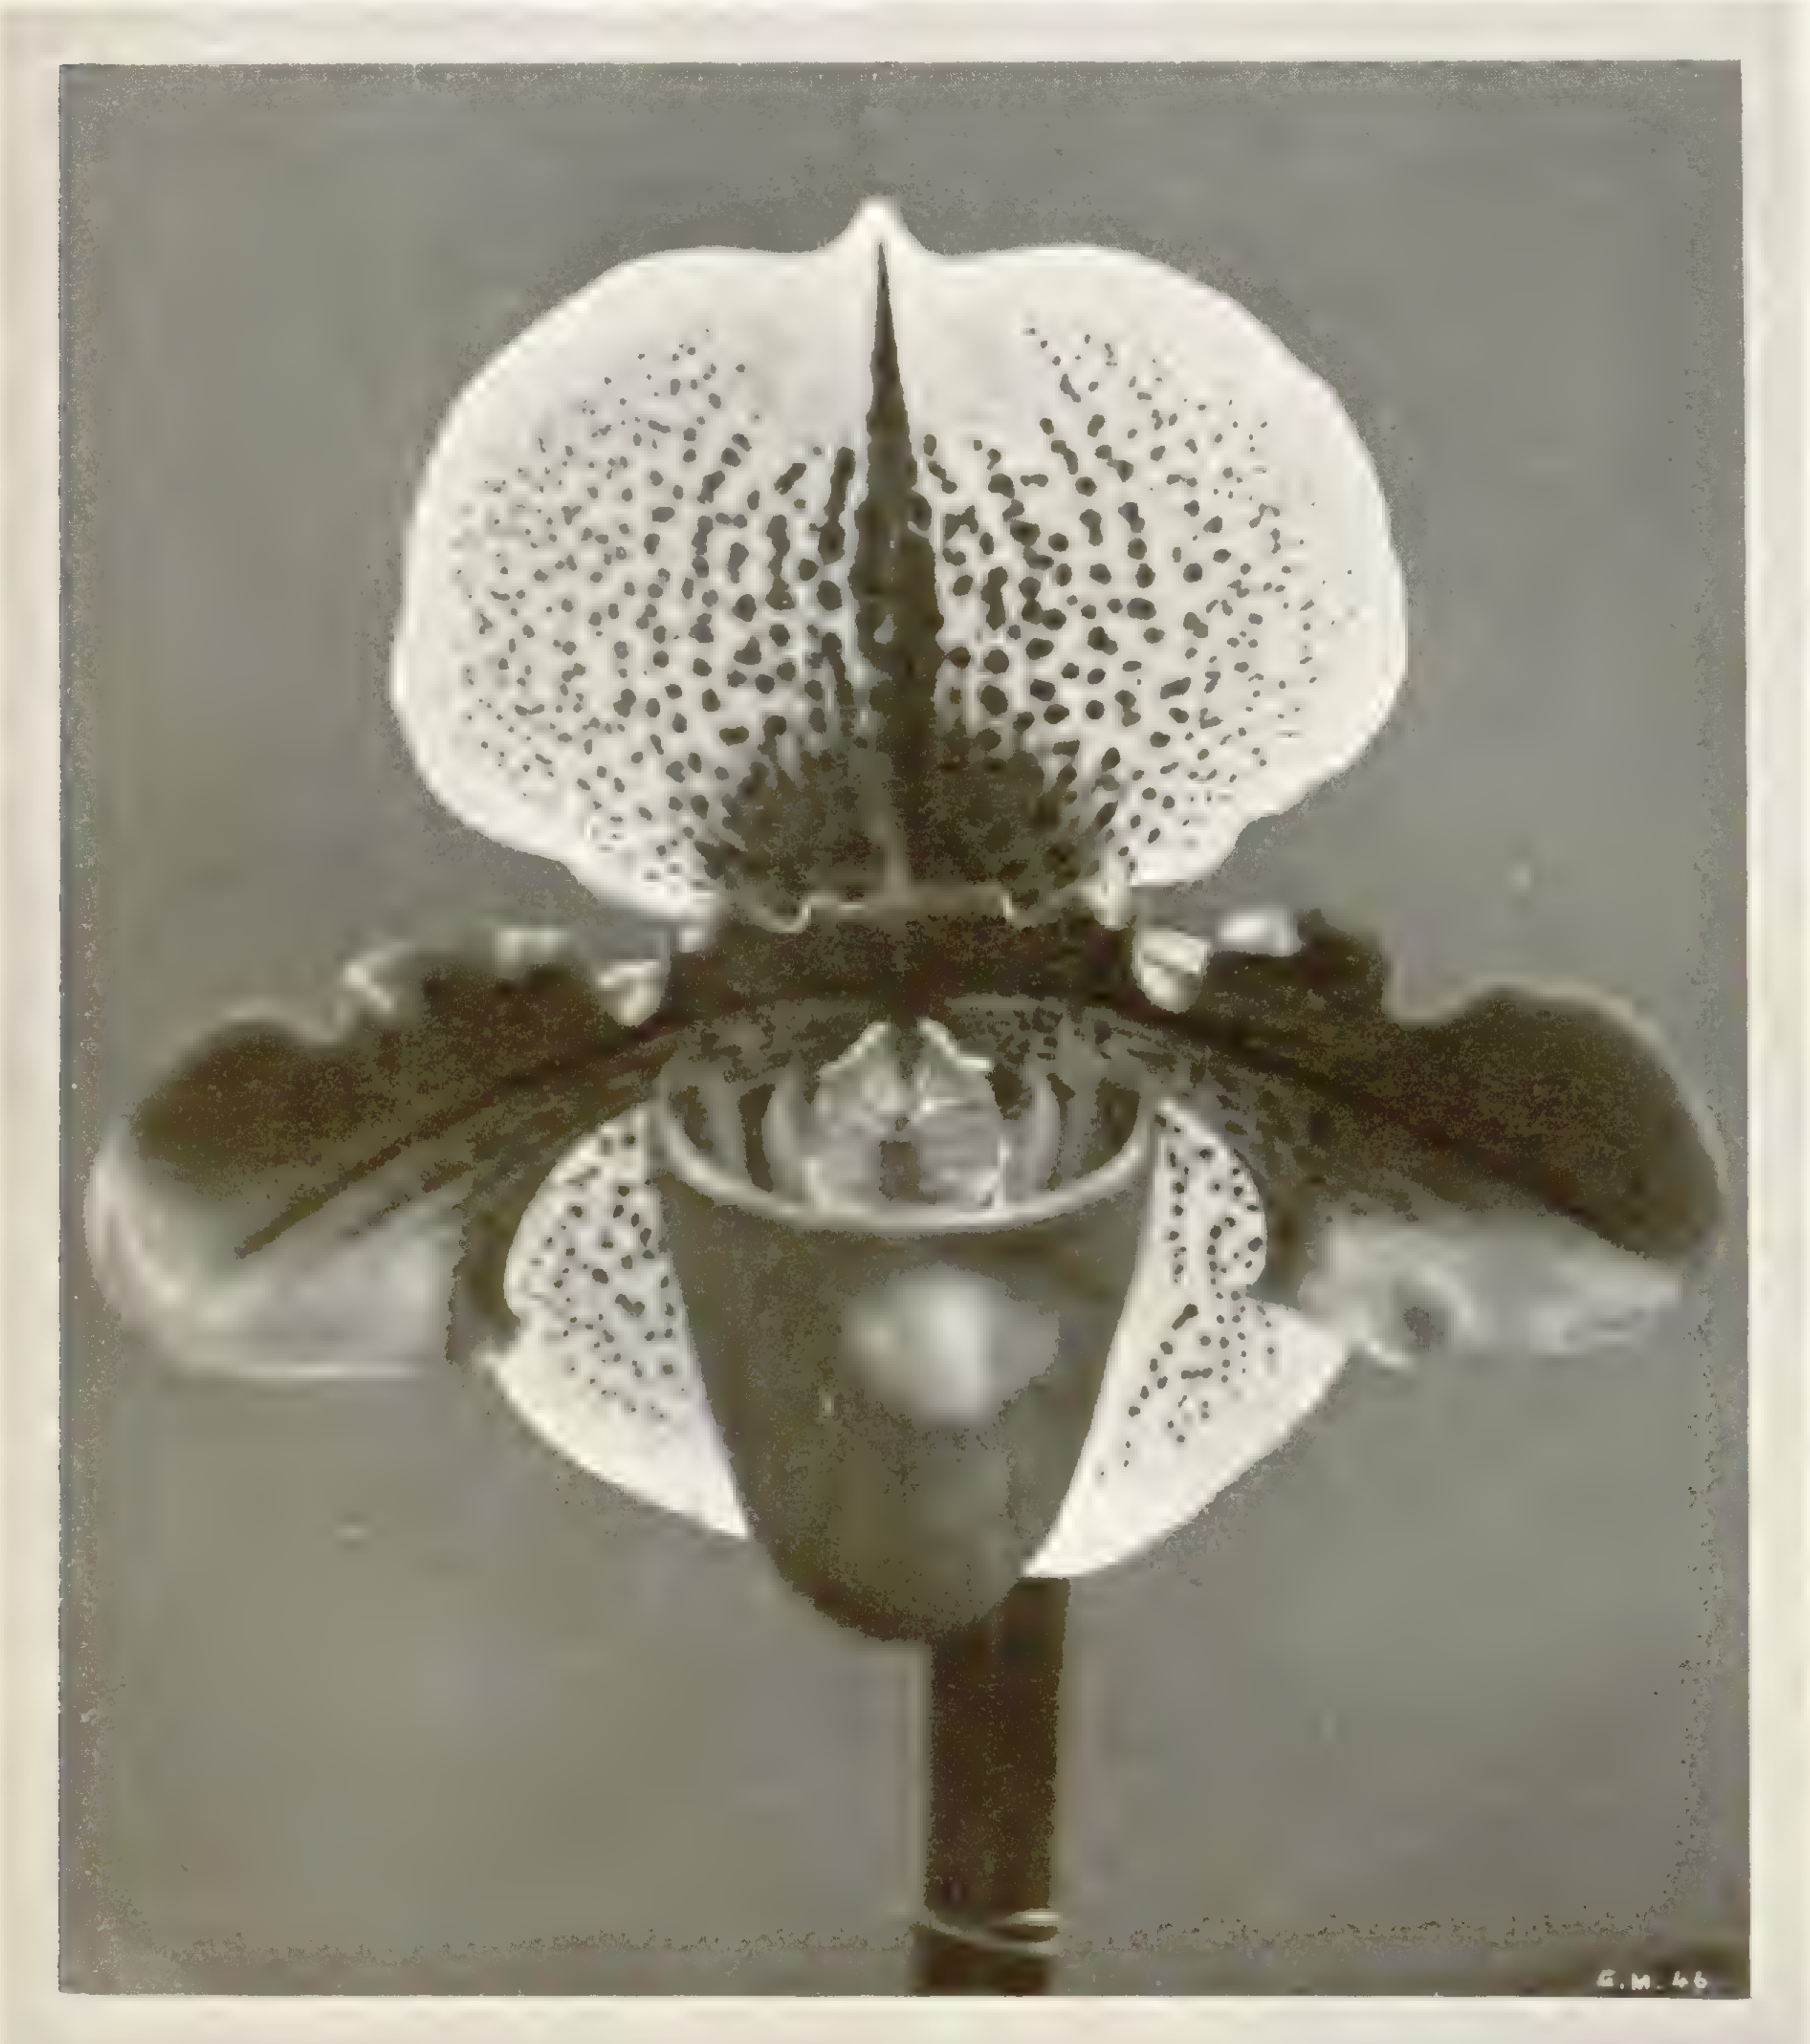


LÆLIO-CATTLEYA NELLA.

A handsome free-flowering hybrid, flowers very deep, dark rosy-purple, with old gold markings in the throat. F.C.C., R.H.S., December 19. Messrs. Jas. Veitch and Sons, Chelsea.

the prizes offered at the leading classes at many shows has had much to do with a lack of competition and enthusiasm; on the part of executive bodies I consider this is an error of judgment. I shall be met with the observation that, as the public do not support them, the committee must, therefore, reduce prizes. To this I say "No." You can reduce the number of classes (there are several in all prize schedules that would not be missed), for if you deprive the public of their chief attraction, naturally their support is lost.

The lack of new and highly desirable varieties as an improvement upon older sorts is an unmistakeable fact. It is safe to say we have no variety now in any one colour that stands out in the same manner that Mdme. Carnot did as a white, and F. S .Vallis as a yellow; and, going back further, it is doubtful if we have aught as good as Boule d'Armas in 1882, or even Mdme. Clemence Audiguier three years earlier. There is no denying the fact that we are badly in want of a pure white outstanding variety now that Mrs. A. T. Miller is on the wane, and in the same way there is an opening for a desirable yellow.



CYPRIPEDIUM LORD WOLMER, WESTONBIRT VAR.

Flowers large, white, with purple spotting, green and brown. A.M., R.H.S., December 19. Lieut.-Colonel Sir George Holford, Westonbirt, Tetbury, Gloucester.

One of our best authorities as a raiser, whose opinion I value most highly, tells me the downfall of the Japanese varieties is entirely owing to the folly of taking them off the boards, and, he adds, perhaps also to the absence of good money prizes. I do not think it will be denied that the introduction of vase classes has done much to check the introduction of new varieties of Japanese blooms. At the most, as at Edinburgh, only fifteen varieties are required in any one class, and that is quite a small number to obtain; when the best prizes were offered for four dozen blooms, distinct, so many more varieties were required to be grown, but if there are no purchasers, vendors are not to blame, because it is a costly matter to grow so many new varieties.

In England the bulk of vase classes do not extend beyond eight varieties, and in those cases the prizes are not adequate to the cost of transit, and this latter item has done much to limit competition. At Northern shows a vase class of any pretension is almost unknown; certainly it is not a popular item in the schedule. When first introduced the method of arranging the blooms in vases appealed to some critics, but experience has shown that the change has not been for lasting good.

I fear there is still another reason why large blooms have become unpopular in private gardens. Too much space, time, and expense have been devoted to their production, mainly for exhibition, and too little regard paid to the smaller or more decorative varieties, consequently some slight friction has been caused, ending, as was sure to be the case, and properly, too, in the complete cessation of exhibiting in that department. The sensible gardener who puts his employer's interest first is bound to score in the long run, but, unfortunately, that is not the universal rule. I might say more, but fear I have already trespassed too far on valuable space, and must, perforce, leave the remedies for future occasion.

E. Molyneux.

NEW PLANTS, ETC.

BUDDLEIA OFFICINALIS.

This species bears a general resemblance to B. asiaticus, and, like it, is a greenhouse subject. B. officinalis was collected by Mr. E. H. Wilson, in China. It has green leaves, with whitened undersides, and downy stems. The spikes of bloom are six or eight inches long, and composed of small clusters of pink flowers, each little flower having a yellowish throat. A few plants in pots would prove useful in a conservatory or winter garden during the winter, because of the sweet honied fragrance emitted. A.M., R.H.S., December 19. Messrs. J. Veitch and Sons, Chelsea.

CYPRIPEDIUM ROYAL SOVEREIGN.

A striking cypripedium, with large flowers and a particularly broad oval dorsal sepal. This organ is blush white, with a green base, and is freely spotted with bright purple. The brownish petals have dark spots. F.C.C., R.H.S., December 19. Messrs. Sander and Sons, St. Albans.

LÆLIO-CATTLEYA NELLA.

A very handsome, rather dwarf, and very free-flowering hybrid, that should prove very useful, especially if it flowers regularly during the winter. The large flowers are of a deep dark rose-purple hue, the lip being very large and well formed, with old gold veinings in the throat. F.C.C., R.H.S., December 19. Messrs. Jas. Veitch and Sons, Chelsea.

CYPRIPEDIUM LORD WOLMER, WESTONBIRT VAR.

This is a very attractive hybrid, and one in which a very fine form of C. Hera was used as one parent. In the new variety the central sepal shows a remarkable development, and is as large and almost as attractive as the dorsal sepal. The latter is broad and rounded, white with a greenish base, and prettily spotted with purple. The outspread petals are bright green and brown, and the lip is light yellowish-green. A.M., R.H.S., December 19. Lieut.-Colonel Sir G. Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester.

ODONTOGLOSSUM CRISPUM ALCYONE.

A charming variety that carried a graceful spike of fourteen large and beautiful flowers. The petals are rose-tinted, and have a few large spots of bright red-brown; while towards the centre of each white petal there is a cluster of tiny red-purple dots. A.M., R.H.S., December 19. J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), Glebelands, South Woodford.

CYPRIPEDIUM ACTÆUS DURBAR.

The massive and somewhat chubby flowers of this variety of C. actæus were not yet fully expanded, but they showed a remarkable development of breadth and roundness in all the parts. The dorsal sepal is very round, large, and the petals have great breadth for their length, while the short pouch has a wide mouth. Green, white, brown and purple are the colours represented, the latter in the form of spottings on the dorsal sepal. A.M., R.H.S., December 19. Messrs. Charlesworth and Co., Haywards Heath.

CYPRIPEDIUM INSIGNE GATTON PARK VAR.

This variety shows what may be done to improve an old favourite orchid by cross-breeding the finer varieties. The Gatton Park form is derived from C. i. montanum magnificum and C. i. Harefield Hall. The flowers are bold, large, and carried on tall stems. The upper half of the dorsal sepal is white, and the lower part green, but over a greater part of the sepal there are fairly large, bright purple spots. Petals and lip are green, shaded with brown. A.M., R.H.S., December 19. Sir Jeremiah Colman, Bart. (gardener, Mr. J. Collier), Gatton Park, Reigate.

CONTROL OF PLANT GROWTH.

One of the strongest arguments for the use of artificial manures in the garden is the control they give us over the growth of plants, so that we can influence the development of leaf, flower, or fruit, in the matter of size, quality, or colour, at our will. We may take the tomato as a familiar instance. We know that one of the main functions in securing a good set of fruit is a plentiful supply of phosphates, while a too liberal supply of nitrogen causes the growth to become so gross that little fruit will be formed, though when the plant becomes laden with fruit this same supply of nitrogen will have the most beneficial results on the size of the fruits. Therefore we can manure with phosphate at the time of planting and with nitrogen, and perhaps potash, when we want to develop the fruit.

In the case of fruit trees, if we study their growth as a doctor studies a patient, we can give them just what they need to give their growth the desired character and withhold that which will have the opposite effect. When a bush apple tree is making shoots two feet or more in length and few fruit buds, we know it is having too much nitrogen, and though it is not advisable to cut off this superfluity without doing some root pruning as well, we can, by a judicious application of phosphates, encourage the formation of fruit spurs, and at the same time hasten the maturity of the growth in the early autumn, so that it will be favourable to the production of fruit buds the following season. Conversely, when the tree is weak, or exhausted, through overcropping, so that its growth during a season consists of thin shoots a few inches long, it is nitrogen which can restore the vigour of the tree, though potash may be necessary as well if the soil is a light one. We have all seen fruit trees making long, slender shoots with thin light green leaves, and this usually shows the want of potash, the application of which will darken the colour of the leaves, and give them much more substance, as well as heighten the colour of any fruit the tree may be carrying, while the fruit buds for the following season will noticeably increase in fatness.

When we apply farmyard manure to fruit trees we are not giving them a well-balanced plant food, for it contains too little phosphate in proportion to the nitrogen for plant life in general, and this deficiency is accentuated in the case of most kinds of fruit trees, where phosphate plays such an important part in the ripening of the young growth and the early maturity of the fruit. Consequently, when we feed late varieties of apples and pears with a thick mulch of farmyard manure we may increase and prolong the vigour of the growth, not only of the wood but of the fruit; in other words, delay maturity in both, and this will mean that in an unfavourable season the fruit will not have time to finish—that is, it will be lacking in colour and will shrivel if kept till its proper season.

Careful observation alone will enable us to prescribe for the feeding of plants generally to the best advantage, and with the least possible waste of expensive plant foods. Many plants in pots, for instance, are given too much liquid manure, made sick, in fact, but if we discontinue the application for a little while, when we notice the colour of the leaves becoming unusually dark, we shall reduce the risk of this to a minimum.

These notes may serve as illustrations to show not only the value of artificial manures in skilled hands, but the harm that may be done with them otherwise.

Alger Petts.

A VIEW IN THE CHARMING GARDENS OF HOME PLACE, LIMPSFIELD.

A COSY GARDEN.

A cosy garden, like a cosy room, is one wherein everything appears to be rightly placed, and where the whole breathes of comfort to the occupants and the occupier. Some gardens are striking, so much so that a certain scene, or scenes, announce themselves in blatant fashion; some are brilliant, and the recollection of them makes one feel hot even on a cold day; some are so formal as to be frigidly rigid, and we do not care to remember them; others, without possessing any startling or imposing features, present a picture, large or small, of the happy association of plant and tree and flower, and provide a place wherein one would like to live this latter, especially if not over-large, gives a sense of cosiness and comfort, and peace. Just such a garden is the one at Home Place, Limpsfield, and a glimpse at the illustration shows that shelter and beauty—cosiness—are combined in a marked degree. Flowers abound, and they do not exclude tree and shrub, hedge and grass plot, from their rightful positions. There is, perhaps, in these days, a tendency to strive after great effects, and startling innovations, in gardens, and so we must have a care lest we lose the quiet peacefulness that adds such a charm to the surroundings of the home. Home Place is rightly named.

Chrysanthemums.—For full instructions on the Culture of Early-flowering Chrysanthemums in beds or borders for garden or greenhouse decoration, read the Second Edition of Chrysanthemums for Garden and Greenhouse, by D. B. Crane, price 2s. 6d. net; or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

NEW SCHEMES FOR WINTER PLANTING.

The original is not always best, for gardeners of the past have invented many of the fairest plans, colour-combinations, plant associations, and floral ornaments, but novelty is bound to arrest the eye, and so win appreciation for the items of which it is composed. Take the stately delphinium as an example: this is beautiful wherever it appears, but can there be any comparison between the value of a double line of dark and light varieties repeated in the borders flanking a broad grass walk, or that of an equal number of plants dotted over several borders and beds?

This is a glorious feature to create. If there is no grass walk a gravel, or paved one, may be similarly avenued. If there are not dual borders the line of delphiniums can occupy but one side, though that is to destroy the original excellence of the scheme. Where space is great a triple row of the tall plants can be grown: indigo at the back, Royal or cornflower-blue next, then azure, or Cambridge blue. To perfectly carpet such borders several methods can be adopted. The striking contrast of yellow violas may be preferred, the chaste relief of cream-white violas such as Sylvia, the grey-green, ever-attractive foliage of pinks with that of carnations behind—carnations of pale pink, lemon, and white only—the rich harmony of maroon-crimson dianthuses or the pale pink of Bellis perennis roseum. When a taller plant than these dwarfs can be grouped against the delphiniums, nothing can excel heucheras, in the pink and red-flushed white species only.

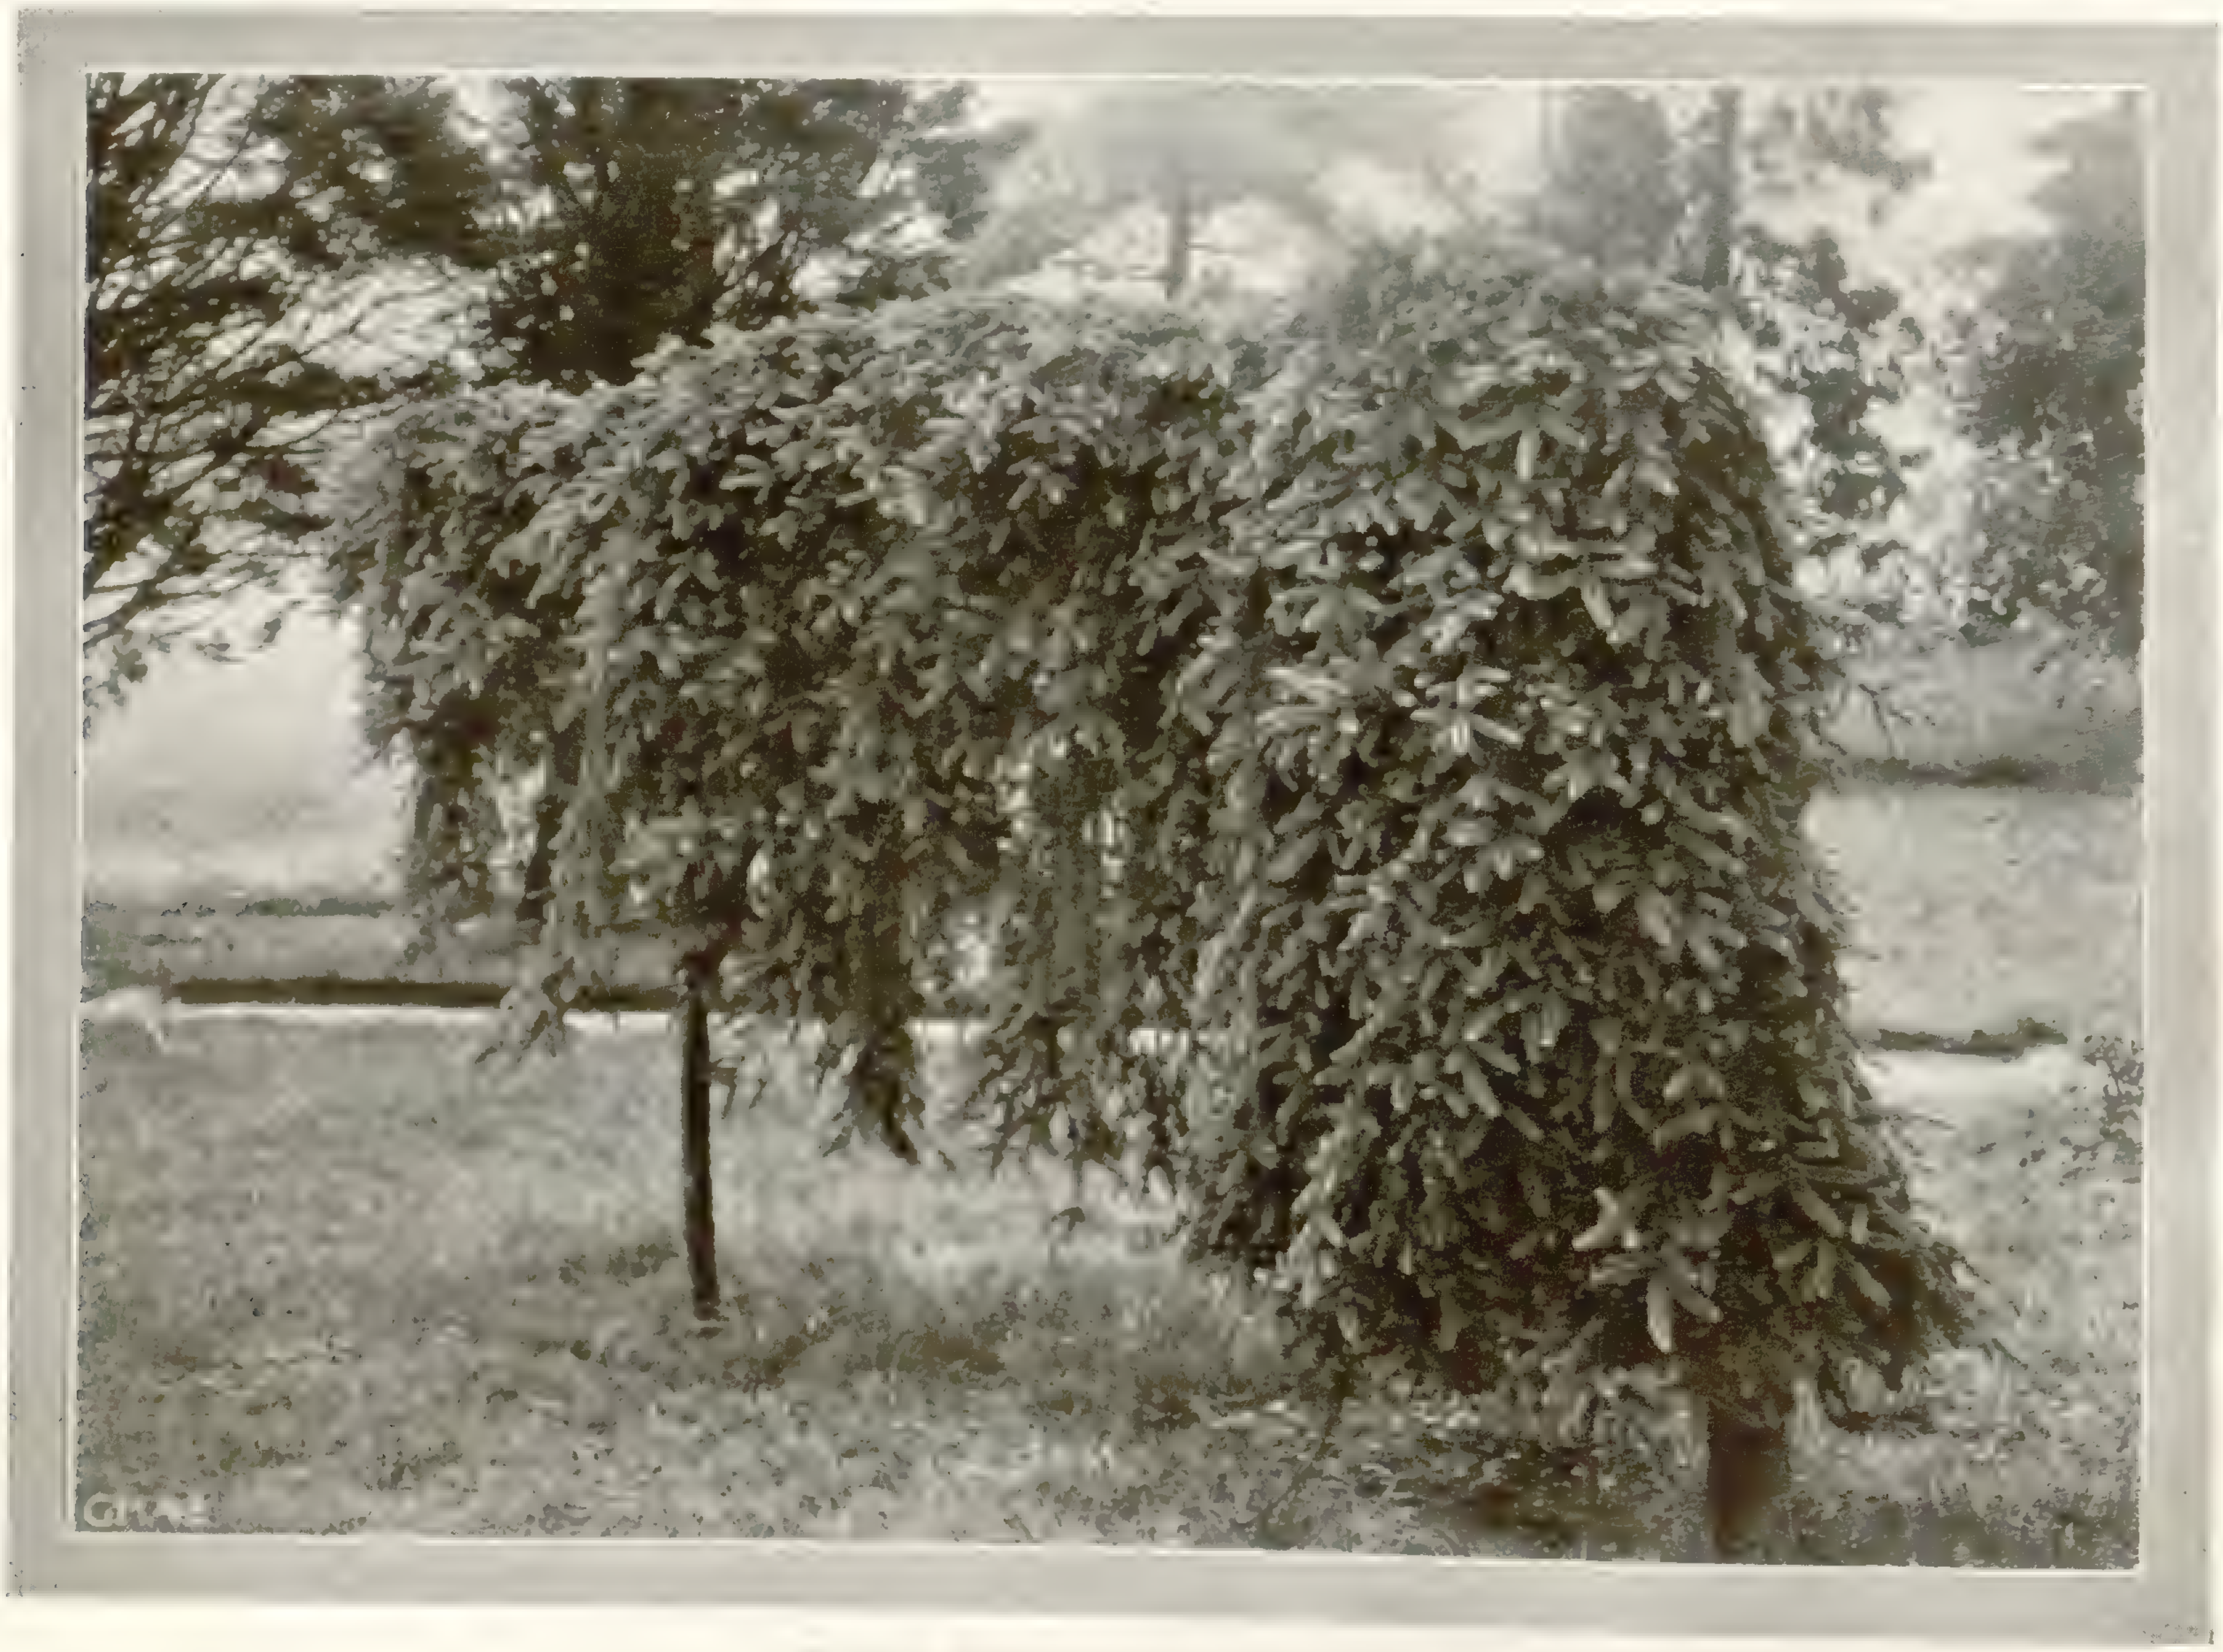
A bed of heucheras ought to be included in every large garden. The merits of the plant are many. The close clustering habit of the foliage makes an admirable covering for all the soil, and is extra beautiful when autumn touches the leaves with bronze and copper. The flower-spikes rise from one to two and a-half feet, to wave gracefully, a mass of fairy-like blooms, above this carpet. Few gardeners grow all the sorts, but a selection, at least, of the following should be massed in a bed, leaving just space for the introduction of a Gladiolus Lemoinei bulb between each two; Heuchera brizoides, brown-purple; H. brizoides gracillima, rose; H. sanguinea, crimson-scarlet; H. s. alba, white; H. Zabelliana, rosy-carmine; H. sanguinea Rosamunda, coral; H. erubescens, white, variegated; H. Edge Hall, pale pink; H. micrantha, white, rose-flushed; H. pubescens, bright rose.

A wonderfully bright feature in a garden consists of a tall bank crowned by gold flowers, carpeted by orange, and covered up the sides by scarlet. This is easily carried out if dwarf sunflowers, gaillardias, yellow chrysanthemums, and yellow Spanish irises for June glory, are used, the space beneath being sown in March with Tom Thumb, Orange nasturtiums, and the scarlet permanent plants chosen are potentillas. Between these potentillas scarlet begonias can be added each June. A wilderness of tall perennials is a singularly exquisite filling for a shrubbery clearing, or any wide border or unoccupied plot of ground. There should be no attempt at sloping the blossom height towards the edge of the space thus adorned. The bold plants should stand two feet apart, and then, if wished, there can be a carpet of some such hardy evergreen as London pride. Delphiniums, Golden Rods, Michaelmas daisies, Chrysanthemum maximum, giant gypsophila, the Plume poppy, or Bocconia cordata, tritomas, phloxes, Campanula pyramidalis, Scabiosa caucasica, rudbeckias, sunflowers, chrysanthemums, Pyrethrum uliginosum, Centaurea macrocephala, Astilbe rivularis, and Achillea eupatorium are but a few of the suitable hardy subjects.

The value of deep crimson or maroon blossom in a garden scene has seldom been properly shown; dark masses of this hue have a wonderful powerfulness, giving contrast for the light-suggesting groups of pale gold, or white. Chrysanthemums, single hollyhocks, antirrhinums, sweet williams, carnations, phloxes, wallflowers, dahlias, and bedding pansies all offer it.

A narrow border surrounding a fine lawn, except for exits and entrances, is always an advantage. The effect is best when the lawn has an undulating edge, or rounded shape, that the border must, of course, follow. To see the feature at its finest, however, the border must be planted with an evergreen carpet, whether of grey, gold, or actual green, and the flowers, a mingling of tender and hardy subjects, should be all of one colour, whether white, crimson, rose, gold, mauve, or scarlet.

M. H.



PICEA EXCELSA MONSTROSA

A well-developed specimen of this singular conifer in the pinetum at Brickendon Grange, Hertford, the residence of J. Trotter, Esq.

The Cockspur Thorn.—This fairly common North American species is, as represented by its large-leaved forms, such as prunifolia and splendens, remarkable for the brilliant tints of its autumn leafage. As a rule there is no mass of one uniform colour, but various tints of red, bronze, yellow, and scarlet are to be found at the same time on one individual specimen. It is not for the sake of its autumn tints alone that this thorn deserves recognition, for its bright red berries are freely borne, while in spring its flowers make it very attractive. Added to this it forms a shapely tree, distinguished throughout the summer by its bright glossy leafage. There are some distinct varieties, with long narrow leaves, and a peculiar spreading habit of growth, but they are less ornamental than the larger forms.—W. T.

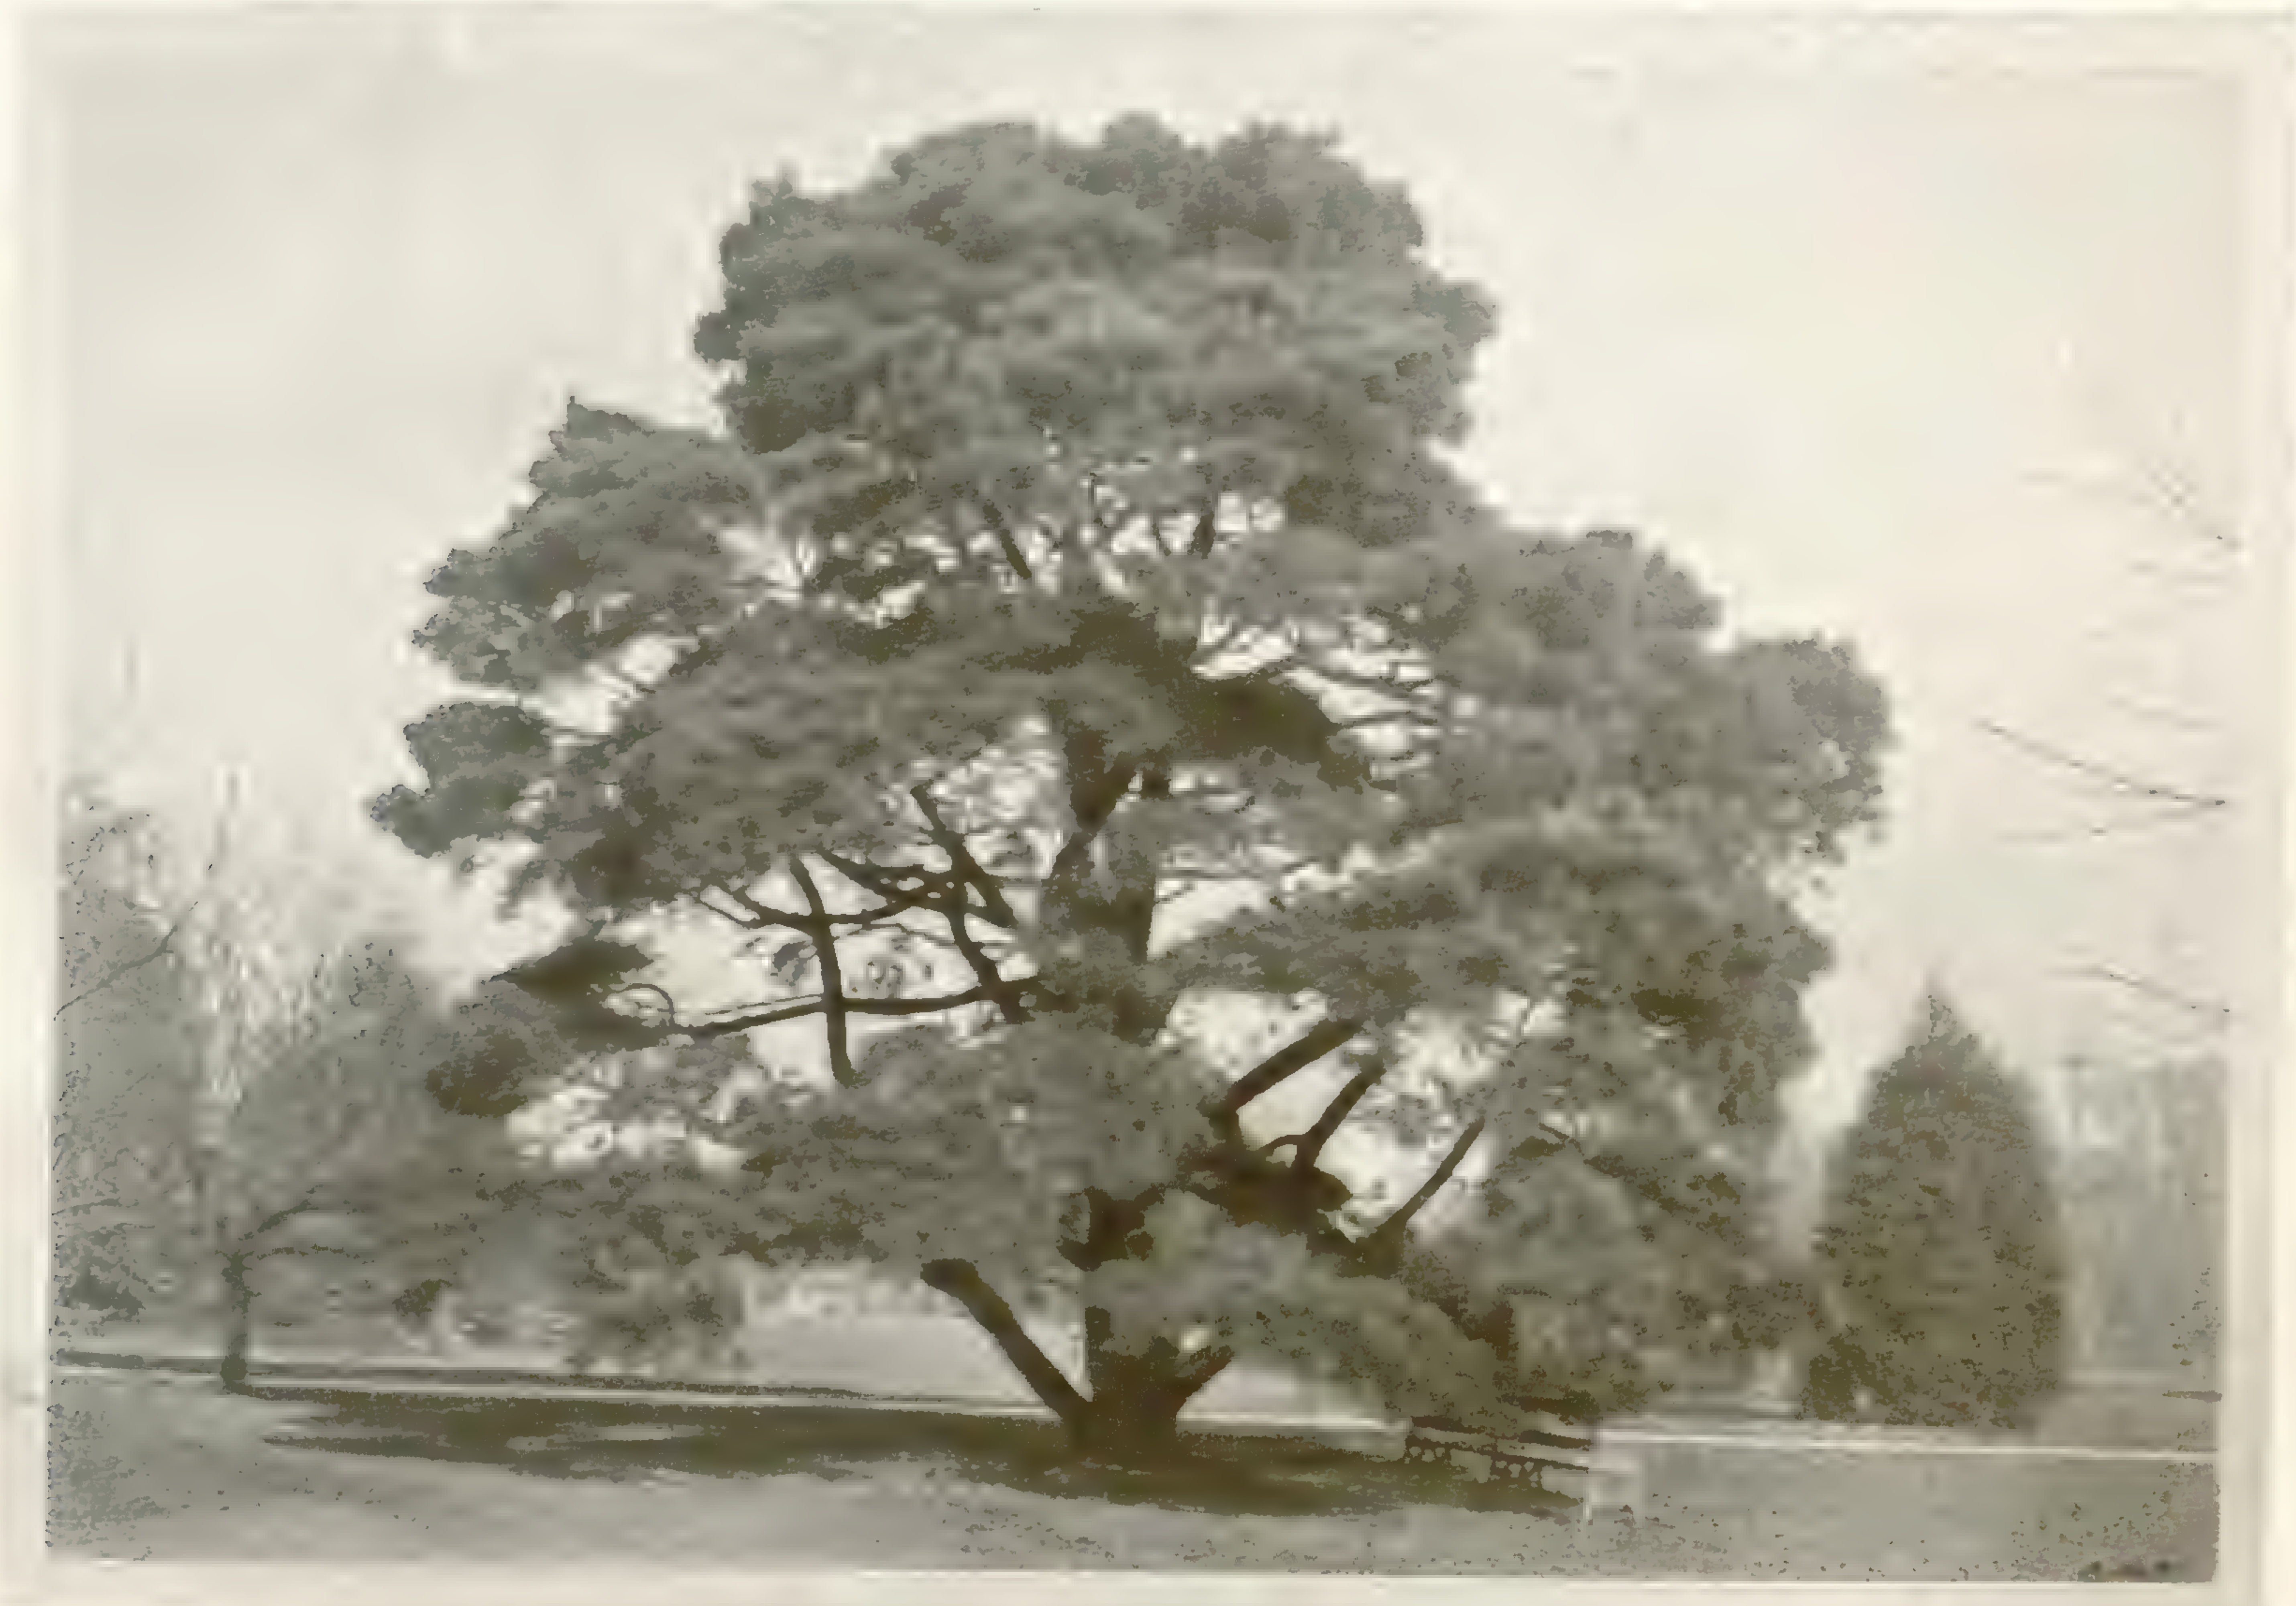
PICTURESQUE CONIFERS.

Coniferous trees are of many kinds, and afford a remarkable diversity in form and colour. There are pigmies that in stature do not exceed two feet, and there are giants that pierce the sky at a height of upwards of one hundred and fifty feet. There are trees that in process of growth form the most perfect pyramids, and there are also trees that assume an irregular outline and attract attention by reason of their rugged appearance. There are also trees remarkable for their rigid growth, and there are others that are characterised by their graceful habit. In the matter of colour there are kinds so sombre in hue as to render it almost dangerous to plant them near water because of the depressing effect they produce under certain atmospheric conditions; and there are others so resplendent in silver and gold as to make the landscape laugh under the influence of the midday sun.

These trees are so distinct in character and varied in colour as to provide an abundance of material with which to produce the most diverse and charming effects in the creation of both garden and park scenery. Planters have not been wanting in appreciation of the claims of coniferous trees, and many are the gardens in which they have been utilised with excellent results; and in not a few they form features that are at once of much interest and highly attractive. Whether they have invariably been used to the fullest advantage is another matter, and with reference to this point it has long appeared to me that too limited a view is taken of the aid they are able to render in contributing to the attractions of pleasure grounds and parks. It appears to have been rather too much the practice to estimate their value from the effect they produce while in a comparatively small state. This may be advisable in the case of gardens that are not of sufficient size to admit of the full development of trees that assume large proportions; but when the planting of spacious pleasure grounds and parks is under consideration, the characteristic features of the trees when they have attained their full size should be taken into account. Some of the species that are remarkable for their grace and beauty when in the earlier stages of their development lose much of their charm as garden ornaments when of mature age, while others do not afford full evidence of their effectiveness until they have reached their full development. For example, not until the tree has reached a considerable age, and formed its low and characteristic round head, does the English Stone Pine (Pinus pinea) show how picturesque an object it is; whereas a specimen of the Deodar (Cedrus Deodara) or of the Spanish fir (Abies Pinsapo) rapidly decrease in beauty after it has commenced to shed its lower branches.

In suggesting that coniferous trees which become more or less picturesque with advancing years should have more consideration from planters than is usually given them, it must not be assumed that there is a desire to exalt them at the expense of those remarkable for their graceful habit or formality of growth; so far from this being the case, the desire is simply to suggest their being planted, where room is available, as supplementary to such kinds, and thus ensure the variety essential to the full enjoyment of the garden. There are many positions in the park, and, indeed, in spacious pleasure grounds, where trees of a picturesque character would be more appropriate than such kinds as Abies Nordmanniana, A. Pinsapo, Cedrus Deodara, Picea Engelmanni, Tsuga Albertiana and other choice kinds that might be mentioned. Judiciously associated with such species as the foregoing, they contribute materially to the general effect by the striking contrast they afford

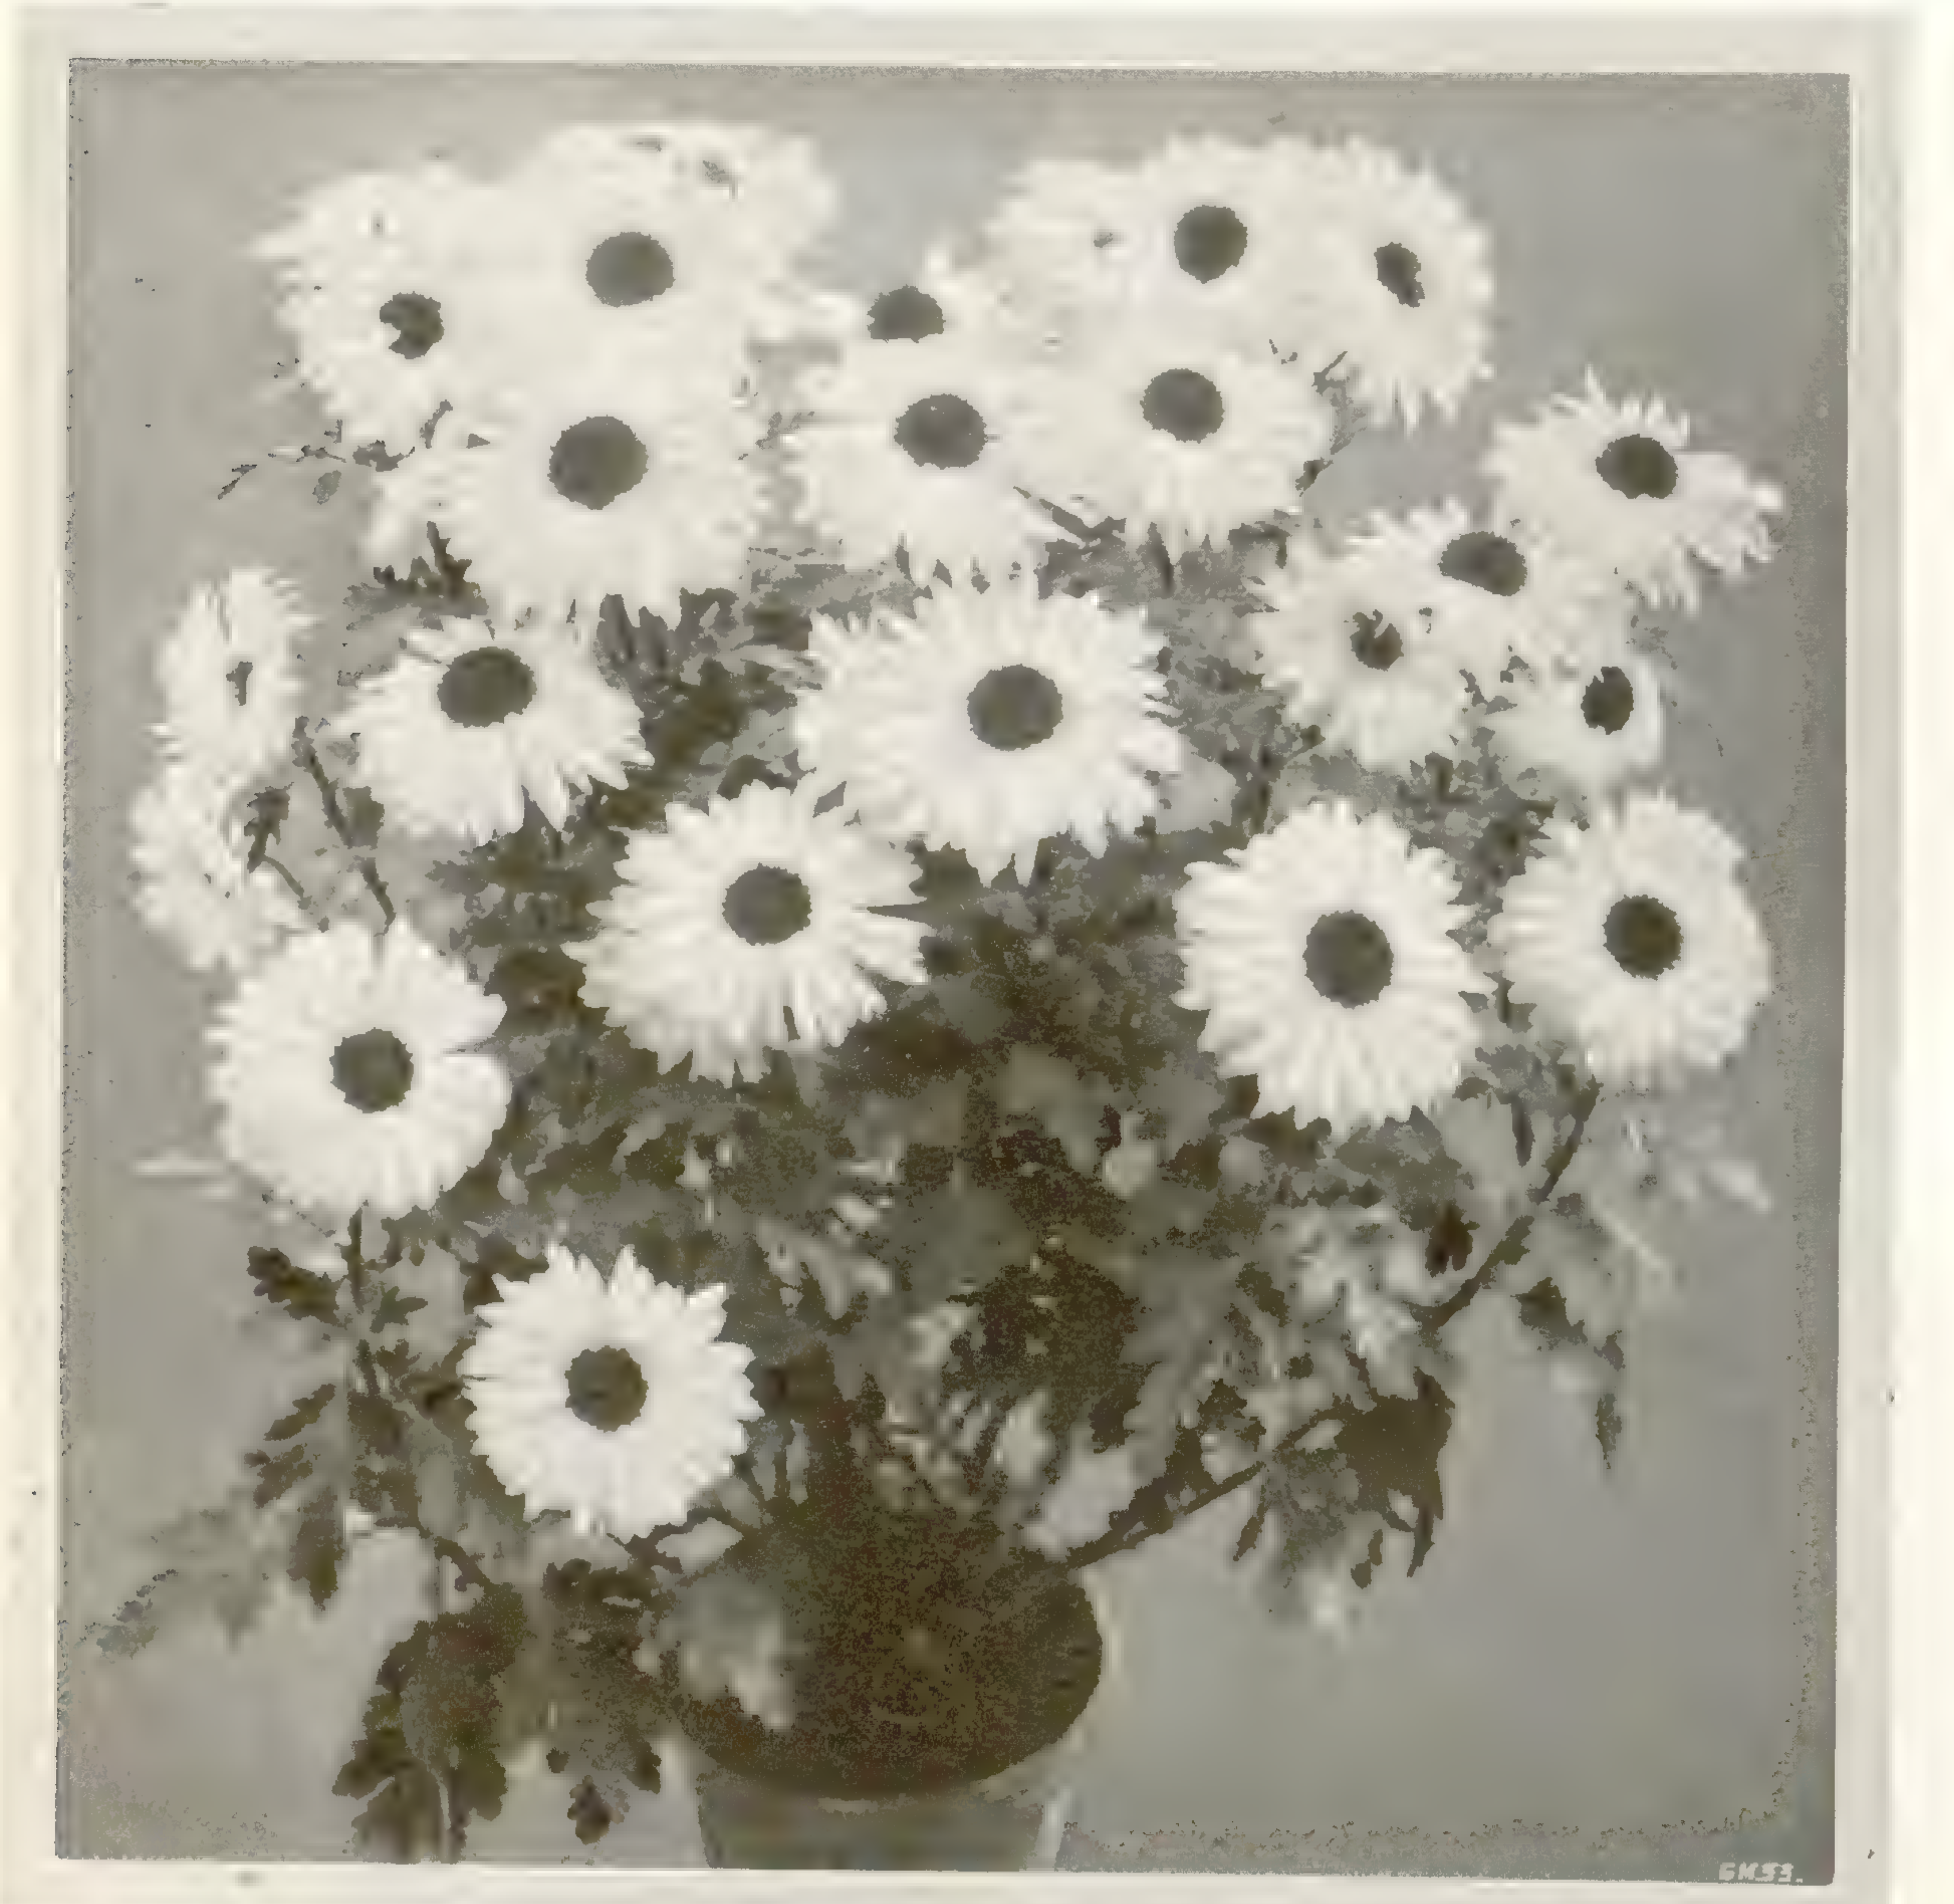
The picturesque conifers of special value for beautifying the park and pleasure grounds are chiefly found among the species of Pinus, and of these the Stone Pine (Pinus pinea) is one of the most noteworthy. In Great Britain the tree attains a height of about twenty-five feet; it commences to branch freely at a short distance from the ground, and forms a dense flattened head. There is a characteristic specimen on the north-west side of the Royal Gardens, Kew, and those who are interested in coniferous trees and have an opportunity of doing so, should make a point of seeing it. The species has from the distant past been freely planted in Italian gardens, where it attains a greater height than in this country, and many are the fine specimens that may be met with, especially in the vicinity of Rome. Different in character, but not less desirable for the garden, is the Bishop's Pine (P. muricata), of which an illustration is given herewith. This species is rather taller than the Stone Pine, and when the conditions are favourable, it rises to a height of about forty-five feet. As in the case of the last-named, stout branches are produced from within a short distance of the ground, but they do not compete so successfully with the main stem, which maintains the lead until it attains a considerable height, when it branches, and the several stems grow at about the same rate. The masses of foliage are so arranged as to produce a distinct and pleasing effect. It has been described as of but little value for the garden, and in the earlier stages of growth it may not be equal to some other species, but when fully developed, as in the case of the specimen illustrated, it is a noble object. Pinus parviflora is a small-growing tree, rising to a height in this country of about twenty-five feet, and is one of the best for planting in



THE BISHOP'S PINE (Pinus muricata).
A characteristic specimen of this picturesque pine in the Royal Gardens, Kew.

small gardens. The head is somewhat pyramidal when fully developed, and if the tree is less picturesque than the foregoing, it is deserving of a place in gardens where coniferous trees are well represented.

The foregoing pines will suffice for the majority of gardens, but where the grounds are extensive or plantings have to be made in the park, the following may be added: The Corsican Pine (P. Larico), a handsome tall-growing tree, with deeply furrowed bark and a picturesque head when fully developed, and useful for its timber, has much to recommend it. The best of its varieties for ornamental planting is Pallasiana, which has a broad head. The Cluster Pine (P. Pinaster) is a stately tree, and valuable for park planting, growing to a great height, and retaining its branches until a late period in life. The Weymouth Pine (P. Strobus) is also useful for the same purpose as the immediately preceding species, and the Scots Pine (P. sylvestris) is sufficiently picturesque to justify it being planted in the park and on the hillside for landscape effect.



SINGLE CHRYSANTHEMUM SWINBURNE.

A white, yellow-centred variety, grown in a 48-sized pot by Messrs. Jas. Veitch and Sons, Chelsea.

One of the most picturesque of all the coniferous trees when it has reached a mature age is the Cedar of Lebanon (Cedrus Libani), but it requires so long a period to reach the picturesque stage that no one can plant it with the hope of seeing it otherwise than during the graceful period of its development. There are some conifers of a weeping habit of growth that are more less picturesque when seen in contrast with the normal forms, and there are a few of the dwarf forms that are highly effective when utilised in furnishing high rocky banks. One of the most distinct of the weeping conifers is Picea excelsa monstrosa, but it can hardly be described as one of the most beautiful. Possibly it may not appeal to any considerable number of tree lovers; but browsing, as it were, among the large number of finely developed conifers in the extensive pinetum at Brickendon range, Hertford, the residence of J. Trotter, Esq., the specimen is of much interest. To give such trees a prominent position, on the lawn, would hardly be desirable, but when a few abnormal forms are associated with a large number of the ordinary forms of the finer species, as at Brickendon Grange, they are of value as illustrating the variability that may be found among the conifers. G.

CHRYSANTHEMUM SWINBURNE.

Messrs. James Veitch and Sons have, during the autumns of 1910 and 1911, shown how splendidly very many varieties of chrysanthemums may be grown into beautiful specimens in quite small pots. The skilful market grower can often give the gardener many helpful hints, but it is not often the nurseryman sets out to show us a new method of cultivating an old subject. We do not say this method (and we have previously described it) is altogether new, but, at any rate, it is not common, though the display of bushy plants in 48-sized pots, each carrying from two dozen to three dozen good flowers, is certain to be copied by very many of our clever readers. Hitherto we have figured decorative varieties so grown, but now we illustrate a single variety similarly managed. This is Swinburne, pure white, with yellow disc, and entirely beautiful. In our issue of December 23 Mr. T. Stevenson told us how to grow single varieties without stopping them at all, and his seven-footers are marvellously beautiful, and very useful for large conservatories. But where such plants cannot be accommodated the late-struck and freely-stopped plants, like that illustrated, offer a fine alternative method; indeed, where space permits, the two methods should be adopted.

ROSA ALBERTI.

Many of the wild roses are distinctly beautiful both when in flower and fruit, and a selection might well be included in those gardens where species are not already represented. The picturesque effect made by some of our British species in hedges in many parts of the country will be brought to mind, while many people are familiar with the large showy hips of the Japanese Rosa rugosa. There are, however, amongst exotic species many which are quite as beautiful as any of these, and some of them more so, for the habit and foliage of the various kinds is more attractive. Rosa Alberti may be accepted as one of this number, for its graceful branches are clothed with dainty, glaucous hued foliage which in itself is effective, but when seen in unison with the bright coral-red fruits, a very charming picture is made. The club-shaped fruits are fully an inch long without reckoning the long calyx lobes, which add almost half an inch more to the length. At the widest part they are about half an inch in diameter, but they narrow rapidly towards the apex. The unusually bright-coloured fruit is very conspicuous, and it lasts in good condition for a considerable period. R. Alberti is a native of Turkestan.

W. D.

HELIANTHEMUMS.

The value of the sun roses for creating a summer display in the rock garden cannot be overestimated. For dry, sunny positions, where the plants can hang over a ledge of rock, they are invaluable, and, although the blossoms of the single varieties are but short lived, some only lasting one day, yet they are produced in such abundance that an excellent colour effect is maintained for a considerable period. The double varieties last longer, but are not so effective as the singles, nor are they produced so freely, and the growth of the plants is not so rapid. It is not advisable to plant them close to any choice dwarf subject, as there is the danger of the latter being overgrown and smothered.

Regarding soil, a good sandy loam will be found most suitable, but helianthemums are not by any means fastidious, and will thrive in almost any ordinary garden soil, providing it is not too heavy. Propagation is easily effected both by means of seeds and cuttings. The seeds should be gathered and sown as soon as ripe, either in pots or boxes, which have been filled with a mixture of loam, leaf-soil, and sand. When sown, the pots or boxes should be placed in a cold frame, and shaded until the seedlings appear, after which time the shading must be dispensed with. When large enough to handle, the young plants should be put into small pots, and kept growing in the frame. Repotting will be necessary when the plants have become well-rooted, and good stock will thus be obtained. Cuttings root freely if taken in August, and dibbled into a bed of sand in a close, cold frame. When sufficiently rooted, they should be potted into small pots in which they should pass the winter, affording them frame protection until the following spring, when repotting will be necessary. The young stock must not be allowed to suffer from excess of moisture during the winter months; it is much safer to keep them rather dry than to overwater them.

After being planted out for four or five years the growths become weak and thin, and the plants lose much of their vigour, therefore it is advisable to maintain a young stock in readiness for vacancies.

No rock garden is complete without a good collection of these attractive plants. Among the singles there are H. macranthum, with large creamy-white blossoms; The Bride, pure white; Miss Lake, a splendid yellow; Cecillia, pale yellow; H. tomentosum, bright yellow, with whitish foliage; H. venustum, scarlet; Mrs. Sydney Smith, red; and H. rhodanthum, rose with a yellow eye. The doubles include Jubilee, said to be a yellow sport from the well-known Mrs. Earle; H. alba plena, white; Bronze Queen, a very fine bronze; H. roseum multiplex; Mrs. Earle, crimson; H. tigrinum plenum, salmon; and H. serpyllum plenum, yellow.

Gnaton Gardens. E. C. Pooley.

BONE MEAL.

This is one of the most useful of all artificial manures, if artificial it can be called, and if only one such manure is used, it is pretty safe to say this should be the one. It is prepared by boiling the raw bones under sufficient steam pressure to remove the fat, after which they are ground into a somewhat gritty meal which contains from 4 to 5 per cent. of nitrogen and 45 to 48 per cent. of phosphate. Though the fat has been removed, the cartilage remains, and this has the effect of retarding the breaking up of the particles after the meal has been applied to the soil, so that agriculturally, it is considered a very slow-acting manure. As, however, used on garden soils, which are usually of an acid character, or as an ingredient of potting compost, where the roots are brought into very intimate contact with it, the action is much quicker, though even then the results of its use the second year after application should be little less than the first year. Where, however, the soil is sandy or poor in humus it would be better to use what is known as steamed bone flour, the difference between this and bone-meal being that the boiling of the raw bones is conducted under such a high pressure of steam, some fifty pounds to the square inch, that not only is the fat removed, but the whole of the cartilaginous matter as well, with the result that the bones can be ground into a finer meal which acts much more readily in the soil, but it is at the expense of a considerable portion of the nitrogen, the analysis being only 1 to 1½ per cent. of nitrogen, though as much as 60 per cent. or more of phosphate. Neither bone meal nor flour is recommended for soils rich in lime—a rare condition in gardens—by reason of the extreme slowness of the action in such a case.

Of the three most important plant foods—nitrogen, potash, and phosphorus—the last-named is the element which is usually considered to be most concerned in the production of floriferousness and fruitfulness, and if we use bone meal for fruit trees we may expect to see very good results. As it is only slowly soluble it should be applied in the autumn, or early in winter, at the rate of two to three ounces to the square yard and lightly hoed in. If the trees should fruit the following season—and of course the blossom is all formed long before this—it will hasten the ripening of the fruit—especially desirable with late varieties of apples and pears in dull seasons—and if the trees do not fruit that year the bone meal will prove valuable in encouraging the development of fruit buds for the year after, while the soluble, or readily available, nitrogen is not sufficient to cause any undue luxuriance of growth. It should be applied at the same rate and in the same manner to all established plantings where little or no digging in of animal manures can be done, as, for instance, those of asparagus, rhubarb, raspberries, and bush fruits generally, herbaceous borders, and roses. The deep colour of roses after the buds have been dressed with bone meal is often a subject of remark, as it is, too, in the case of chrysanthemums where it has been a constituent of the potting compost. For this latter purpose it is indispensable, the rate of use being about a pound to the bushel of soil. As it is of a lasting nature, and becomes gradually available, it is especially good for plants which will be a year, or perhaps two or more years, in the same pots, while the lime which is set free as the phosphoric acid is absorbed, keeps the soil from becoming sour—a common condition of the soil in pots when the plants are not given a frequent shift. For lawns it should be applied late in the autumn at the rate of five pounds to forty square yards, thereby improving the quality and colour of the herbage without undue encouragement of the clovers, which is such a feature of the use of basic slag, and sometimes a disadvantage on tennis lawns, and without strengthening that baneful horizontal growth of the cock's-foot grass which is often a result of the application of a purely nitrogenous manure.

For sowing bone meal in the open ground still weather should always be chosen, for otherwise that part of it which is in the finest state of division, and therefore the most valuable, will be blown away and lost. The same applies with even greater force to steamed bone flour. As both can be stored in the dry for a good length of time there is no need to pay the high prices usually charged for small quantities. Bone flour, being almost entirely deprived of animal matter, may be stored for years without undergoing any change, but bone meal, unless kept in a very dry place, may not remain in such clean condition after a year or two.

Alger Petts.

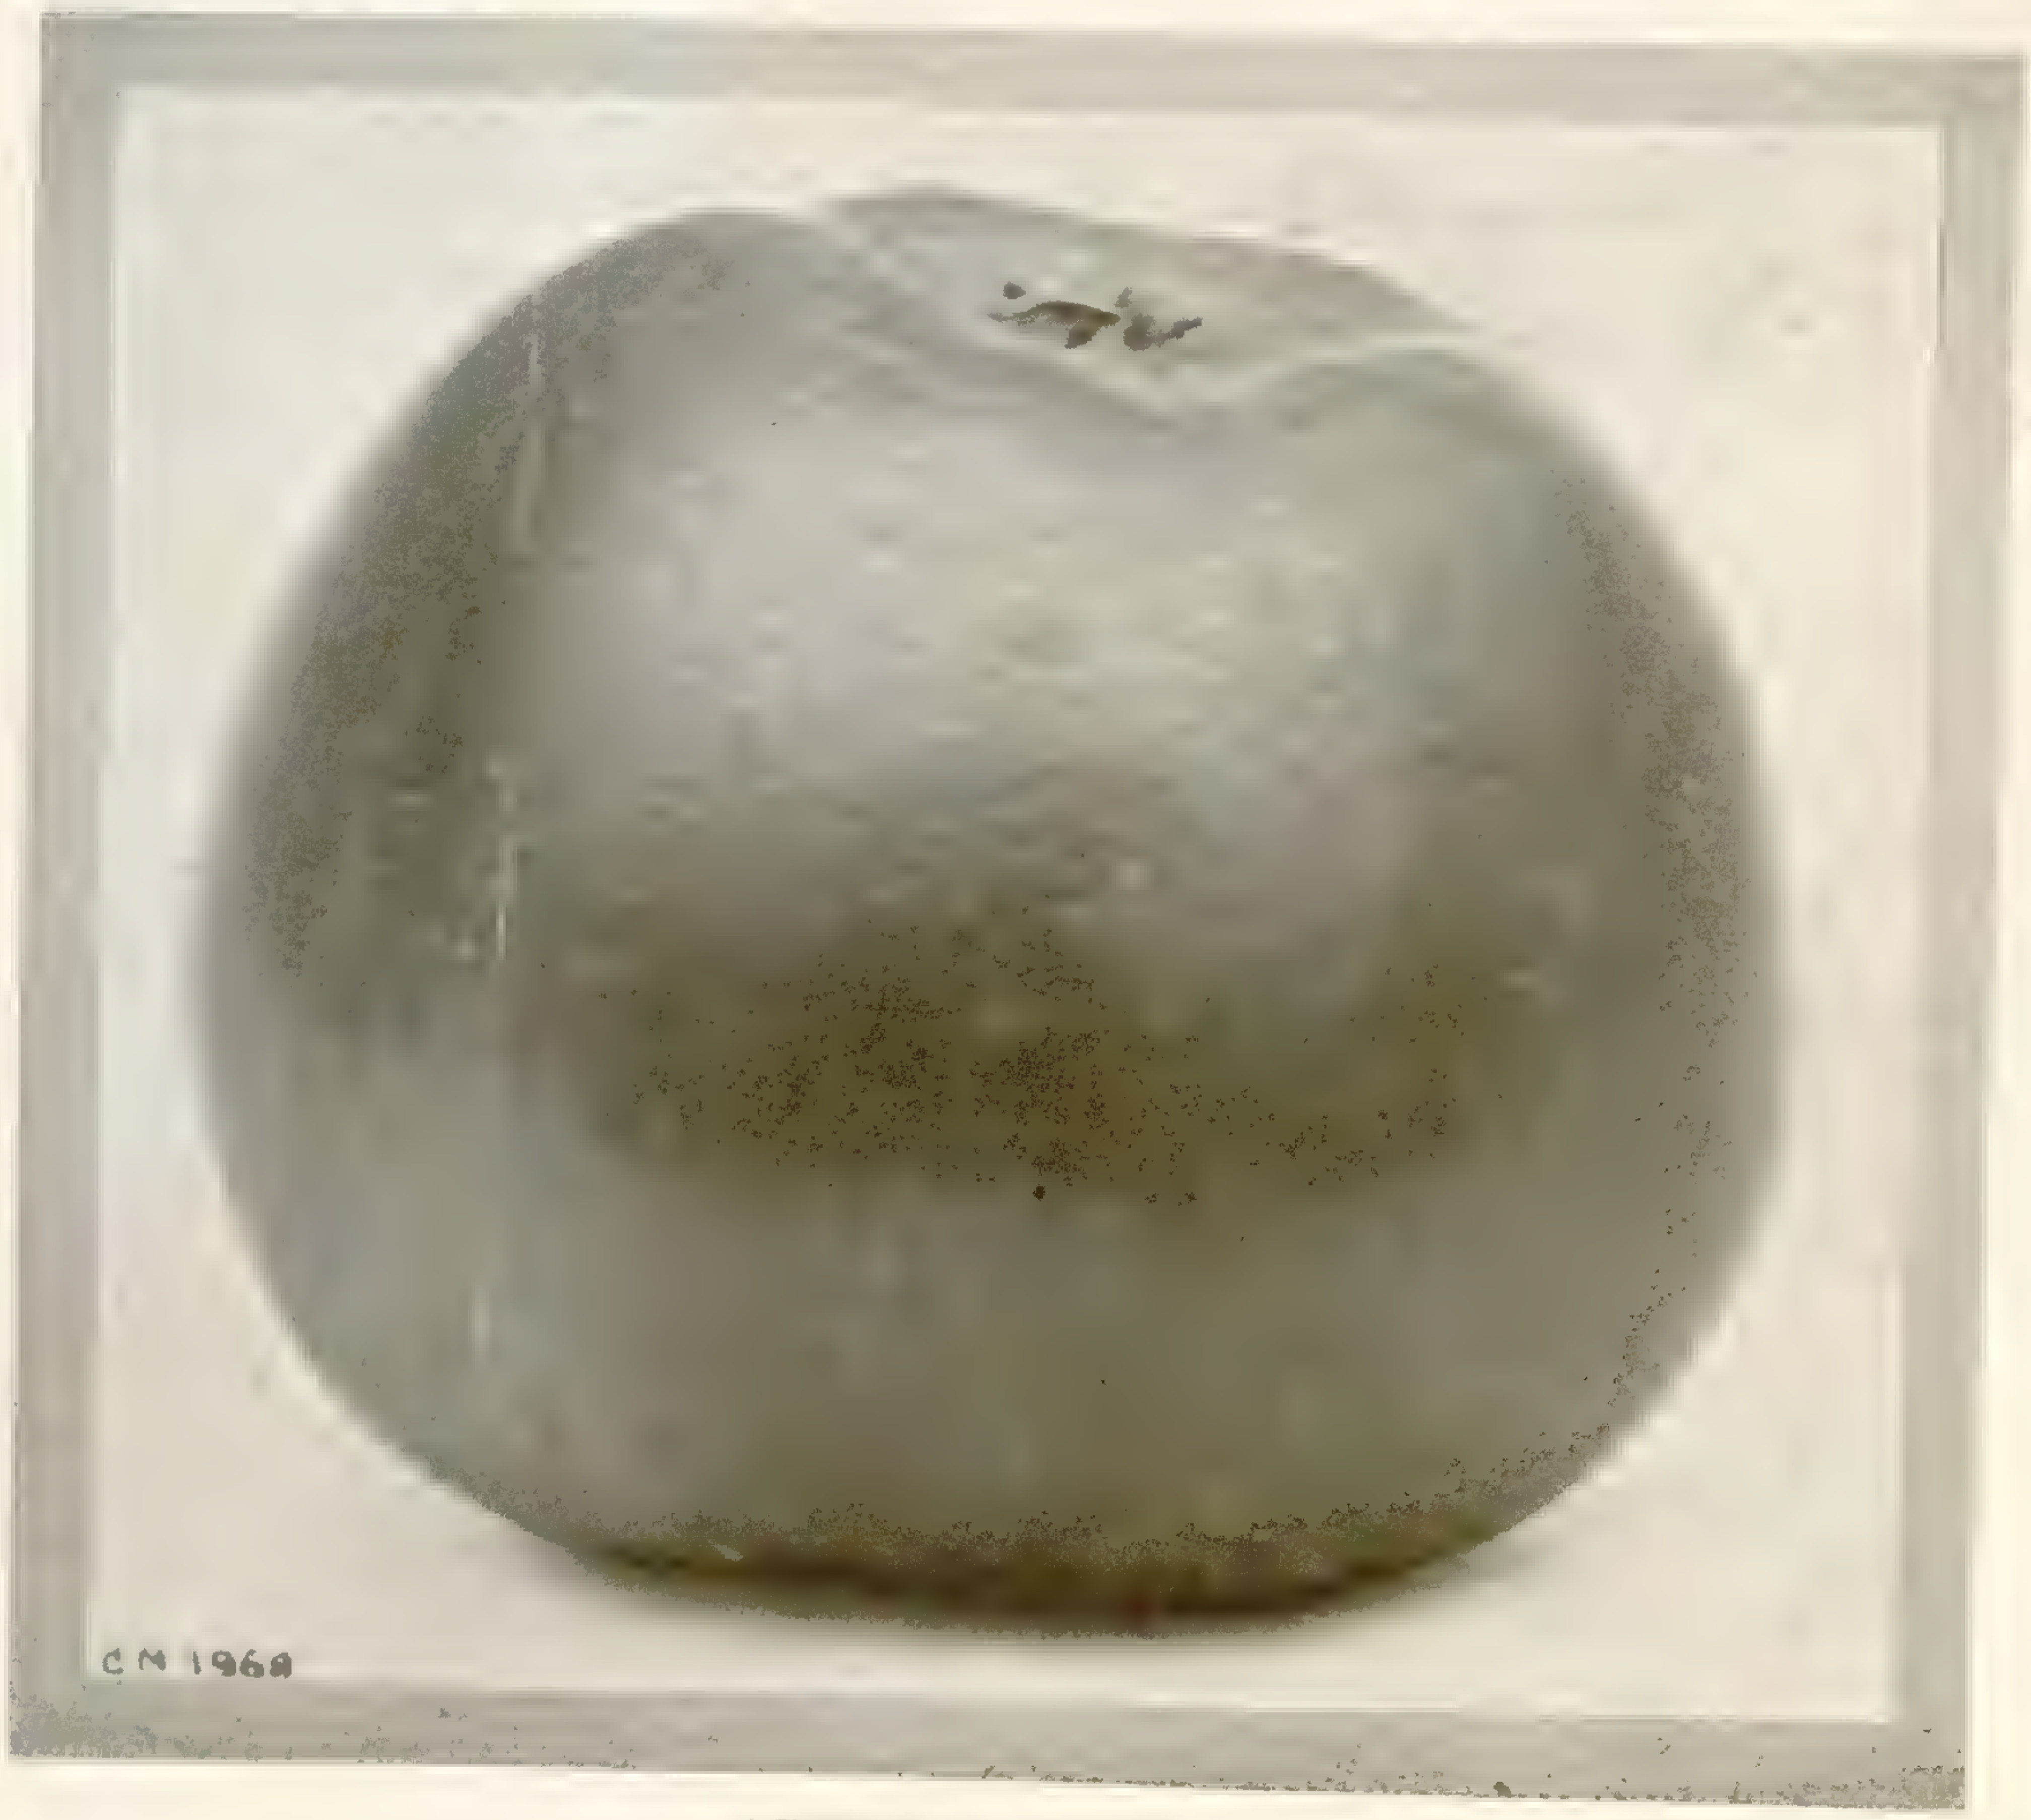
DESSERT APPLE PAROQUET.

Of the several excellent varieties of apples that have in quite recent years been introduced to cultivation, the one here referred to will, in all probability, when its merits are better known, be held in very high esteem as a dessert fruit. The general character of the trees indicates a sparseness of growth, and it is therefore well adapted for wall culture, more particularly for filling up vacant spaces between more robust varieties, where quite small plants prove very productive, and in autumn the numerous well formed and highly coloured fruits render such trees very attractive and interesting when viewed from a near standpoint.

The individual fruits resemble in size and contour those of the well-known King of the Pippins, while the deep crimson colouring, which gradually spreads over the whole outer surface, is very pronounced, and pleasing in appearance. Catalogues give the season of Paroquet as December and January, but several years' trial here afford convincing proof that it may be kept far beyond the last-named month, with no other special means than that of a cool, airy room. Thus circumstanced, its season of usefulness may be extended until April, with the fruits as plump and inviting in appearance as at midwinter.

As already stated, the tree is very productive, especially so when worked upon the paradise stock, hence thinning the crop should have timely attention to prevent undue exhaustion from this cause, as well as to aid in the full development of the fruits, which at any time are not large, but remarkably handsome and well coloured. Paroquet was raised by Mr. Charles Ross, and received an Award of Merit from the Royal Horticultural Society in October, 1899. Probably Worcester Pearmain was one parent of the variety.

Galloway House Gardens. James Day.



APPLE PAROQUET.

A distinct and handsome dessert variety of high quality, raised by Mr. Charles Ross.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

DECIDUOUS CALANTHES.—As the different members of this section pass out of flower, the plants should be placed under strict resting conditions, either on a shelf near the light or in a light, dry position on the stage. It is usually the case that room is fully occupied with other plants, and the calanthes have to make shift during the late winter and early spring months, and where space has to be curtailed in this way it is a good plan to turn the plants out of their pots and place the pseudo-bulbs, carefully labelled, close together in shallow boxes; cover the bottom of the box with a thin layer of chopped sphagnum, mixed with sand, and as the roots are laid in, carefully pack (sufficiently firm to secure the plants in an upright position) with the same material. No root moisture will be required until the pseudo-bulbs produce new growths in early spring. As soon as root action commences the plants are easily separated and potted. It is not advisable to place the plants where there is any great fluctuation of temperature; about 55 degrees will be ample until the new growths make their appearance, when warmer conditions, with more moisture in the atmosphere, will be desirable.

LATE-FLOWERING CALANTHES, such as C. Sanderiana, C. Williamsi, C. Regnieri, and the hybrids of this section should be kept where they may receive every encouagement to develop their flower scapes during the next two or three weeks; it is surprising how rapidly they expand their flowers as soon as the turn of the days is reached.

PHAIO-CALANTHES. — These semi-deciduous bi-generic hybrids are not always the easiest subjects to deal with; as soon as they pass out of flower it is advisable to place them in a warm, but rather dry position, with only sufficient root moisture to keep them plump. Excess of moisture either in the atmosphere or about the roots invariably encourages the development of black spotting which causes considerable trouble, frequently eating into the base of the pseudo-bulbs before giving any warning of its existence. Dry conditions appears to be the best means of checking its ravages.

PHAIUS.—The early-flowering hybrids of the P. simulans section will now be producing their flower scapes from the base of the last made growth. If it is desirable to have the plants in flower early in the season, they must be now placed under conditions where they may have the necessary encouragement. If for flowering in April and May, the more the plants are retarded the better. If kept cool the plants must be in a reasonably dry atmosphere until the end of January, when more liberal conditions may be afforded. The foliage should be carefully examined and sponged with warm, soft water.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

PERPETUAL - FLOWERING CARNATIONS.—Success in carnation cultivation is only achieved by laying a sound foundation. To this end it is most necessary to commence propagation as early as possible within reason, to allow the plants abundance of time in which to grow and become matured. Again, the selection of cuttings plays a most important part. These should be taken from strong, healthy plants only, which are true to character. The thin, weak cuttings produced at the top of a flowering growth are useless, but those produced about mid-way up the growth are the best and most likely to maintain the standard of the particular variety. Two methods of propagation are used in general, viz., that of "heel cuttings" and that of "pipings." The latter method is the one I employ, as I find it gives a larger percentage of rooted cuttings than the former. By this method the cutting is taken between the thumb and finger, and, with a sharp upward jerk, is severed from the parent plant. No knife is necessary, except to shorten the lower leaves.

FOR STRIKING THE CUTTINGS a small propagating case should be placed on the stage in a house with an even temperature of 50 degrees, and where a little bottom-heat can be obtained. Fill in to a depth of three inches with sharp silver sand, and insert the cuttings about two inches apart. Well water them in and cover with glass. This method far supersedes the old-fashioned one of using pots, it being more economical both in labour and material. Too much artificial heat must be avoided, as this only excites the cuttings, and makes them long and weak. Do not allow the sand to become dry, but, on the other hand, excess of moisture must be guarded against, as dampness is one of the chief causes of the dreaded carnation disease. If the glass is removed in the evening, and left off all night, it will reduce the amount of moisture which would be caused by condensation. Do not permit any cold draughts to reach the cuttings, but gradually harden them off, so that by the time they are rooted they can be fully exposed to all light and air. The cuttings should never be allowed to grow in the propagating case, but be potted off into small thumb pots as soon as they are nicely rooted. Careful attention to all details will ultimately bring its own reward in a profusion of blooms. The question of the best and most profitable varieties is one to be carefully studied, and I hope in an early issue of the Gardeners' Magazine to give my opinion on this subject.—H. Grubb, Porter's Park Gardens.

HARDY FRUITS.

PRUNING BUSH FRUITS.—This may be done as soon as opportunity permits, and the quarters may then be well manured, lightly forked over, and set tidy for the winter. Many prefer to leave gooseberry pruning until spring, with the idea that less damage will be caused by birds, but this is doubtful, as one may often notice very dense trees practically denuded of all fruit buds if nothing is done to prevent the attack. Gooseberries should be thoroughly thinned, cutting away the weakest and all interlacing growths, so that the hand can pass freely into the tree at fruit gathering time. The upper growth may be left at full length at the tops of the bushes, shortening the lower wood somewhat, or much dirty fruit will result as the trees become loaded. A few cuttings should be rooted each year, selecting medium wood of the best varieties, and cutting this into foot lengths; all the lower buds must be picked out to provide about six inches of clean stem above the ground. These will root readily if planted firmly in well cultivated ground.

CURRANTS.—Red and white currants once trained are but little trouble at pruning time. Summer pruning should always be carried out if possible, and little will then remain to be done, except to shorten all lateral growth to a couple of eyes or so during the winter. If trained as cordons or gridirons, on walls, the trees are easily protected, and the fruits will hang fit for use until the end of September. Cuttings may be treated in the same manner as for gooseberries.

BLACK CURRANTS will need to have their branches well thinned, cutting a few clean away each year, to induce strong growth from the base. The only way to keep clean, healthy trees is to cut rather hard, and at the same time work in abundance of good manure during the winter.

GRAFTING.—Preparations may be made for grafting, and trees to be operated on should be headed off a few inches above the point where it is intended to graft. The wood should be carried away or burned as soon as possible. When grafting, avoid putting on many varieties, as this is sure to cause disappointment in future years; select one or two reliable kinds that are known to do well in the district, leaving many of the newer kinds to be still further tested. Some effort should certainly be made to limit the number of varieties of apples; at the outside fifty varieties should be ample for any private garden and a greater bulk of serviceable fruit would be obtained from half that number.

AFTER-MANAGEMENT.—Standard trees that have already been grafted should be shortened back the first and second year to encourage strong growth, after which they may be allowed to grow away if making good growth, thinning the side shoots only to allow the sun and air free play through the trees.—J. Whittle, Cheveney Gardens.

THE KITCHEN GARDEN.

SEAKALE.—If the stock of roots has not been lifted, the matter should be at once dealt with to allow the ground they occupy to be manured, and prepared for next season's crop. The side roots can be cut away, and the crowns stored in sand or ashes outdoors ready to be forced as required. Thongs for next season's planting should be selected and cut into lengths of about six inches, and also similarly plunged in ashes or sand until the spring. Continue to place quantities of crowns in the forcing-house to meet the demand.

EARLY PEAS.—Where a suitable south border has been prepared for this crop, and wind has made the surface dry enough to work easily, seize the opportunity to make the first sowing outside. There are several varieties of the early dwarf class that are very prolific and suitable for narrow borders, such as Chelsea Gem, Little Marvel, etc. These kinds can be sown in rows two feet six inches apart. Varieties such as William the First should be from five to six feet apart, such positions being necessarily protected for the peas by means of sticks, etc., they give excellent sites for early salading plants. At about this time a sowing of early peas may also be made in pots or in boxes made for the purpose. These, if grown on sturdily in cold frames and planted out at the end of March or beginning of April, will afford some dishes a week or ten days previous to those sown on the outside border.

BROCCOLI.—During the last few months the weather has suited the winter broccoli, and they have turned into head unusually well. Where any quantity are showing their flower heads, it will be a safeguard against loss from sharp frosts if they are lifted and transplanted in pits or frames, so that sufficient protection can be given them. Give air on every favourable occasion.

LETTUCE.—The plants that were put out in sheltered borders for early spring cutting are now firmly rooted; apply a dressing of soot to the surface soil, and run the Dutch hoe between the plants during a fine day. Those that are more fully grown, and are planted in frames for blanching in the mushroom house will need special care during the next few weeks, guarding them against damp and sharp frosts.

JERUSALEM ARTICHOKES.—No purpose will be served by allowing this crop to remain longer in the ground. At the first convenient time lift the tubers and store them in sand in the root house for use as required. At the same time select the medium size tubers, and place these by themselves to be in readiness for next season's planting.

ASPARAGUS BEDS.—If the permanent beds of asparagus are not in a satisfactory condition , or part have been lifted for forcing, now is a good time to prepare the site for new beds. This should be trenched and richly manured. If the soil is of a cold clayey nature, care will be necessary when making the beds to see that they are rendered porous by adding plenty of sand on light soil and keeping them above the surrounding level. Avoid the chief cause of failure, i.e., decay of the crowns, during the winter months. — Charles Flack, Cholmondeley Castle Gardens.

AMERICAN BLIGHT AND BIG BUD MITE.

The following is the text of a lecture delivered by Mr. R. A. Harper Gray, M.A., M.Sc., of Armstrong College, Newcastle, at the Northern Fruit Congress, in November:

In dealing with the life-histories of the creatures that are the cause of American blight and big bud, my object is to emphasise the fact that these two infestations have been increasing so persistently during the past few years in this country, that I think the time has fully come when it is the duty of growers to take more active measures in order to check the increase of these pests that cause so much loss and deterioration in our orchards and plantations.

American Blight.

American blight is an example of a very common condition of our apple trees, caused by the presence of a species of the many aphides or "greenfly" that are so abundant in our gardens. The familiar wool-like "growth," which is really a product of the woolly aphis (Schizoneura lanigera), causes the disease to be easily detected in our orchards. The woolly aphis is downy when immature, and is then of a pinkish colour, but becomes some shade of brown when full grown. It possesses a head with two antennæ, three pairs of legs, two pairs of transparent wings, and piercing and sucking mouth parts.

The life-history of this pest is exceedingly interesting. In spring the "mother-queens" which have been hibernating in crevices in the tree, produce, not eggs, but living young, which feed, grow, and moult under the "wool" which they produce. Soon these become mature, and also produce living young aphides, and we may here point out that there may be several such generations during a single summer. It is said that some of these larvæ change into a pupal form or "nymph," from which winged females appear; these may fly to other parts of the tree, or even to other trees, where they start a new colony by producing young like the wingless forms. As the cold weather approaches, a few males and egg-laying females have been observed to make their appearance in the colony, and the female, after laying a single egg in a crevice of the tree, dies—her dead body forming a protecting covering to the egg during winter. Then, when spring comes round, the little larva appears, which soon becomes the adult "mother-queen," ready to start the first of the generations that are to be produced during summer.

Such is a brief account of the life-history of the Woolly Aphis, and, when we consider the number of aphides that may appear on a single tree, each aphis being provided with a piercing and sucking mouth, we are better able to realise the extent of the damage that can be done by such comparatively small individuals.

They are, of course, particularly injurious to young stock, into the tender bark of which they can so easily insert their tubular mouths in order to suck out the sap. The result of the many small punctures that are thus made is that the cells of the tissue are damaged, wet may get in, and the twig becomes rough and deformed owing to the abnormal canker-like growth that is set up in the soft tissues. Indeed, this swollen and deformed condition is often mistaken for canker, and it would appear that Canker very often follows an attack of Woolly Aphis. This does not mean, of course, that the presence of the Woolly Aphis is essential to the spread of Canker, for I have known of cases where American Blight has been present without any sign of Canker fungus. Still, one must admit that the wounds formed by the Woolly Aphis may, and do, aid the Canker fungus in getting a foothold on the trees.

So far we have been referring to Woolly Aphis as if it confined its attention to the parts of the tree above ground, and it is because nurserymen have in past years confined their own attention to the pest only as it has appeared on the branches and twigs that there have been so many failures in the treatment of the infestations. It is extremely important, therefore, that it should be more widely known that the Woolly Aphis also attacks the roots, as well as the parts above ground. It is due to ignorance of this fact that the pest has been introduced so often in past years with new stock. No matter how carefully nurserymen may go over their nurseries, they may still send out infected stock, simply because they are unaware of the fact that the roots are also attacked by the Woolly Aphis. The forms found on the parts of the tree below the ground appear to be the same as those living about it. They reproduce and develop in the same way, and suck the sap from the roots, thereby producing swellings and cracks. Migration takes place from the trunk and branches to the roots, and vice versa; but it has been noticed that the migrants from above show a preference for the trunk below the ground surface, and that on the approach of spring these return to join the aërial colonies.

The fact that this root form is evidently establishing itself successfully on the roots of apple trees in Britain is worthy of the most serious consideration on the part of our nurserymen, as failures in treatment may be due to overlooking the presence of migrating individuals.

Prevention and Treatment.

From what has been said, it will be seen that the treatment of American Blight will be satisfactory only when we get rid of the subterranean forms of the pest as well as the aërial forms. There are many washes which, if properly applied, will destroy the aërial forms, but space will not permit of the composition of these washes being set down. It should be pointed out, however, that, to be successful, the washes should be sprayed on the trees with considerable force, and that where there is much "wool" present, as much as possible should be removed to allow the wash to reach the insect.

Mr. Theobald, in his recent book on "Insect Pests of Fruits," recommends for winter use, the old caustic wash or the improved Woburn wash; while for summer, either soft soap and quassia, or a weak paraffin emulsion. Whatever wash is used, it must be applied thoroughly.

With regard to the root form in the older trees, the injection of carbon bisulphide into the ground is the only remedy as yet known—two to four ounces for each tree being the quantity used. A special form of injector is used, so that the depth of the injection is about six inches—four or more injections being made at distances of some two feet from the trunk of the tree. These injections should be carried out in dry weather before April.

Young stock should be fumigated for 45 minutes with hydrocyanic acid gas before being planted—1oz. of sodium cyanide, 1oz. of sulphuric acid, and 4oz. of water being used for every 100 cubic feet of space. We may here note that sodium cyanide is now being used instead of potassium cyanide, owing to its greater strength as compared with potassium cyanide, which often contains many impurities.

Big Bud.

Big bud in the black currant is caused by the Black Currant Gall Mite. This pest has been known to exist in this country for sixty or seventy years, and the disease caused by it has been persistently spreading during the past few years. During 1907 it was recorded as having attacked white currants, and also red currants, so that it is well worth the particular attention of horticulturists. All cultivated varieties of the black currant are liable to the disease caused by this strange-looking mite.

The mite is all but invisible to the naked eye, being scarcely a hundredth of an inch long. Its body is divided into two regions—a broad anterior part protected by a shield, in front of which protrudes a snout-like head bearing the piercing and sucking mouth parts, and an elongated abdominal part with transverse rings bearing rows of projections. At the end of the abdomen there are two rounded flaps, which can be brought together so as to form a muscular sucker, by which the mite can raise and support itself. At the front end there are four legs, five-jointed, and each bearing bristles and a claw; while on the body there are five pairs of bristles. The creature is whitish or pale green in colour, and is semi-transparent.

The life-history of the mite has not been entirely worked out, but we know the main points. A large number of the mites are found sheltering and feeding in the buds during winter. Some of these buds may contain comparatively few, and may open out in March. The mites are thus exposed, leave their hiding place, and probably perish. The important or vulnerable period in their career is when they migrate from badly infected buds which do not expand, and from partially infected buds which may open late, i.e., from about the middle of April onwards, according to the nature of the season, to the middle of June. This is the period for treatment, for then they may be found on the leaf-stalks, shoots, flower-stalks, and flowers, and even round the new buds that are to be the future homes of the migrants.

It is interesting to observe their method of migrating. They crawl along, or assume an upright position as if waiting to be carried away by insects, etc. If they fail to get lodgement on a passing animal, they drop from their "waiting" position, and may land on a bud or on the ground.

These, be in noted, are the adults, and when the females enter the buds they are ready to proceed with egg-laying. The eggs hatch out in due course, and the swollen buds crowded with new individuals may be seen at the end of August and into September.

It will thus be seen that the disease may easily be spread by the wind, on the clothes of men, by insects such as ladybirds and bees, etc., or by the propagation of diseased cuttings from infested stock.

Prevention and Cure.

Methods of prevention and treatment are always difficult when a pest takes up its abode in the substance of a plant or tree, and this is the difficulty we find in dealing with the Big Bud Mite. Some suggestions, however, may be helpful.

To begin with, only clean stock should be used for propagation. According to Theobald, the French varieties are free from this mite, though growers have told me that the French varieties are as bad as others. Mr. Theobald, however, also admits that "in one or two places I have seen the French as bad as any other variety, but such is very ususual." Fortunately, cuttings are, according to Pickering, easily freed of the pest by being immersed for ten minutes in water at a temperature of 115 degrees Fahr. before planting.

Hand-picking in plantations is, of course, an excellent check to Big Bud, as also is the free use of the knife on diseased twigs. The hand picking should be done two or three times a year, and it is a good plan to pick off any buds that are in close proximity to the diseased ones.

In connection with the treatment of Big Bud, I must mention that Mr. A. H. Pearson, of Nottingham, in answer to an enquiry, has kindly supplied me with the following information: "I have proved that soft soap and quassia will cure the worst attack of gall mite, if one sticks to it, but the spraying should be every ten days from the time the mites emerge in March, to early June. If the weather prevents spraying for any lengthened period, the cure will be retarded, and it may take two years instead of one to clear the plantation; in the case of a bad attack there will generally be a few big buds the second season."

Conclusions.

I think I have said enough to show that these infestations are proving menaces to be reckoned with in fruit growing, and that therefore it behoves our nurserymen to wake up to the fact that strong measures must be adopted to check the evil. There seems to be a likelihood that, in the near future, compulsory inspection of nurseries will be the rule, but I consider that something more should be done—that attention should not be confined to our nurseries, but extended to all gardens and plantations. This, I think, will be clear after what we have said about the means by which American Blight and Big Bud may be spread.

It seems to me, therefore, that advice should be available from research and educational centres, and that leaflets, such as those issued by the Board of Agriculture, should be judiciously distributed by our horticultural societies. At the present time full advantage is not taken of the free distribution of leaflets by the Board of Agriculture. Further, County Councils should have increased power to enforce protective measures.

If a disease breaks out in a certain county mere advice as to what should be done is not enough, for there may be some gardens—private gardens they may be—which may still be harbouring the pest, through lack of interest on the part of the owner, so that when the neighbouring nurserymen have taken the trouble to eradicate the disease from their nurseries, the pest may be soon spread again from one or two private gardens by the wind, birds, insects, etc. I have often been struck by this danger when I have seen small gardens—some not very well cared for—adjoining the plantations of nurserymen. Such cases are examples of the futility of individual efforts, and the position of horticulture compares rather unfavourably with that of agriculture in this respect, when we consider the measures that are taken to prevent the spread of anthrax, swine fever, etc.

But, further, granting that such measures were to be adopted, what a blind and incomplete—we might even say, insular—policy it would be, if compulsory inspection were the rule at home, while all the time infected stock were being imported from the Continent and elsewhere. Our colonies, America, France, etc., have adopted a wise policy of protection in so far as the horticulturist is concerned, for, in some, certificates are demanded, while in other countries the stocks are treated with fumigation immediately on landing.

I think, therefore, that what I have said with regard to the life-histories of the two pests that are the cause of American Blight and Big Bud, ought to open our eyes to the stupidity of adopting half measures in endeavouring to eradicate or check these and other such diseases.

Chrysanthemum Caprice du Printemps. — Old chrysanthemum growers will remember the various sports that emanated from the at one time popular incurved variety Princess of Wales, while, coming down to more recent times, that popular outdoor kind, Madame Marie Massé, has been prolific in this respect. None of them, however, surpass, even if they equal, the record of Caprice du Printemps, which has sported into various colours, all of which are exceedingly valuable for decorative purposes. A particularly interesting collection of these sports was on view at the Horticultural Hall on November 7. Beside Caprice du Printemps itself, with purplish-rose flowers, there were Kathleen Thompson, crimson and gold; Greening's Caprice, lilac; Red Cap, ruby red, yellowish centre; Purple Cap, White Cap, and Yellow Cap, whose colours are indicated by their respective names. The last mentioned was given an Award of Merit. All these varieties possess the good habit of their parent, and they are now established favourites for market culture, as good specimens can be grown in five-inch pots.—W. T.

SEAWEED AS MANURE.

The Composition of Seaweed.

The composition of seaweed is largely dependent on that of the sea water by which it is surrounded. When it is first thrown up seaweed holds mechanically a considerable amount of water, part of which will drain away and part evaporate. Wet weed may contain as much as 80 per cent. of water, and even 85 per cent. is recorded; well-drained material contains about 60 per cent., while weed dried by exposure to air in a shed contains 10 per cent., or even less. Seaweed carted by the farmer would probably contain about 75 per cent. of water on an average.

The following table shows Russell's analyses of several seaweeds and of materials commonly gathered at the same time. The samples of fucus from Jersey and from Croyde were cut from the rock; the Thanet sample of fucus was thrown up by the tide. The materials gathered with the weeds, but quite different from them, included Zostera marina, or eel grass, which has green grass-like leaves, and grows in shallow bays in many districts. It is not a true grass, but is more nearly allied to pond weed (potamogeton). Salicornia is a chenopod, and glyceria is a true grass. Sea mat is the tough brown flat structure commonly found with seaweed; in the sea it consists of a colony of zoophytes, but when cast up on the shore and dried the organisms perish. The organic matter present contains about 9 per cent. of nitrogen, a high figure characteristic of animal residues, but much in excess of anything found in plants. The small shells and debris contained no less than 21.8 per cent. of calcium carbonate.

Percentage Composition of Dry Matter of Various Seaweeds.

	Fucus ceranoides. Croyde.	Fucus serratus. Thanet.	Fucus. Jersey.
Organic matter	69.80	75.16	73.86
Nitrogen	1.25	2.33	2.25
Total ash	30.20	24.84	26.14
Sand	5.15	3.73	1.24
Pure ash	25.05	21.11	24.90
Phosphoric acid	0.03	0.05	0.66
Potash	3.80	3.70	5.88

Composition of other Substances Collected with Seaweed.

	Zostera marina. Jersey.	Mixed growth. Thanet.	Sea mat. Thanet.
Organic matter	76.32	61.50	25.80
Nitrogen	0.68	2.15	2.37
Ash	23.68	38.50	74.20
Sand	3.62	16.68	25.80
Pure Ash	20.06	21.82	48.40
Phosphoric acid	0.70	0.04	0.04
Potash	0.69	1.28	1.30

An inspection of the table shows that the nitrogen in the dry matter ranges from 1.25 to 2.7 per cent., being lowest in the Croyde samples taken in summer, and highest in the Thanet samples collected in winter. The total ash is usually 25 to 35 per cent., 1 to 5 parts of which are silica arising partly from silicates and partly from sand entangled with the weed. Very little phosphoric acid is present, sometimes less than 0.1 per cent., and never much more than 0.5 per cent.; the potash, on the other hand, varies between 2 and 6 per cent. Soda is present in about the same amount as potash, and there are smaller quantities of lime and magnesia.

The composition of seaweed shows some variation with the time of cutting. Toms' analyses of Jersey seaweeds, made at different times of the year, indicate that weed cut in October is poorer than that cut in March or May.

These analyses further show that laminaria drifting in from deep water is usually richer, especially in potash, than fucus cut from the rocks. The kelp-burners also recognised its superiority as a source of iodine. Hendrick's analyses of Scotch seaweeds bring out the same facts, but the samples were not all taken from the same place.

Barlow's analyses of three species of fucus collected at Padstow (N. Cornwall) in March, 1905, showed the following percentage composition, calculated on the dry matter:—

	Fucus nodosus.	Fucus serratus.	Fucus vesiculosus.
Organic matter	73.99	76.97	71.35
Ash	26.01	23.03	28.65
Nitrogen	1.78	2.88	2.29
Potash	4.47	5.00	6.29
Phosphoric acid	0.29	0.55	0.45

In many respects the results are similar to those obtained by Russell and Hendrick for Thanet, Jersey, and Scotch seaweeds. In the case of F. serratus the phosphoric acid was considerably higher than that found in the Thanet specimen referred to above.

The total alkalies in these three varieties were found to be nearly uniform. Calculated upon the ash, they were as follows (lime was not estimated):—

	Soda (Na2O).	Potash (K2O).	Total Alkalies.
F. nodosus	23.19	17.19	40.38
F. serratus	17.76	21.69	39.45
F. versiculosus	18.72	21.94	40.66

Seaweed is characterised by containing more ash, and less phosphoric acid, but about twice as much potash as ordinary farm crops, excepting such specially rich crops as mangolds, buckwheat, and mustard.

Value as Manure.

The material gathered by the farmer is rather mixed, though one or two species usually predominate, especially if, as sometimes happens, the seaweed is cut from the rocks. Analysis of the Thanet sample which was thrown up by the tide showed the following constituents:—

Fucus serratus	59.7	per cent.
Glyceria maritima and Salicornia herbacea	4.3	,,
Laminaria	2.5	,,
Ulva	1.4	,,
Fucus vesiculosus	0.6	,,
Sea mat	1.2	,,
Miscellaneous debris	30.3	,,

The British results may be summarised as follows:—

	Wet weed as gathered. Per Cent.	Average. Per Cent.
Water	70 to 80	75
Organic matter	13 to 20	18
Nitrogen	0.3 to 0.8	0.5
Potash	0.8 to 1.5	1.2
Phosphoric acid	0.02 to 0.17	0.09

A considerable amount of water is lost on drying in the air, and, if the weed has not been washed by rain in the meantime, its content of nitrogen, potash, and phosphoric acid is increased four, five, or even six fold.

It is difficult to form an estimate of the money value of seaweed to the farmer. The fertilising materials present in one ton of seaweed possessing the average composition would cost 8s. to 10s. if purchased from a dealer in the form of a merchantable manure in a finely divided state ready for putting on to the land. This value is arrived at by allowing 12s. for each per cent. of nitrogen, 4s. for each per cent. of potash, and 3s. for each per cent. of phosphoric acid. No account is taken of the sodium, calcium, and magnesium salts, which on most soils, but especially light soils, would be distinctly beneficial; nor is any allowance made for a possible stimulating effect of the iodides present. It does not, however, follow that seaweed is worth 8s. to 10s. a ton on every farm near the sea coast. The question of availability of its constituents—i.e., of its decomposition under various conditions—would have to be ascertained by careful trials before even a tentative estimate of its money value could be made.

In farm practice seaweed more or less takes the place of dung, but there are several important differences. Seaweed contains no fibre, and, consequently, does not produce the black structureless material characteristic of the dung heap; in decomposing it forms soluble substances which easily wash away. For the same reason it decomposes more completely than dung. It is even said to facilitate the decomposition of dung on light soils and in dry districts, but there is no definite proof of this. A ton of dung and seaweed would break down in the soil more quickly than a ton of dung alone, and would grow an indifferent variety as it does for one of proved excellence.

A good series of slides shown by the society's electric lantern were extremely interesting and the specimens of vegetables making up each picture called forth the highest admiration from his audience. Special treatment for the different kinds of vegetables shown was given by the lecturer, and his instructions were keenly followed by the members. The discussion created lively interchange of questions and answers between audience and lecturer, and many useful details resulted from these inquiries. Owing to a long journey home, Mr. Beckett had to leave early, but before his departure his audience expressed to him their fullest appreciation of his visit and accorded him round upon round of applause, with the firm hope that in the near future he would pay a return visit.

A good number of exhibits were made by the members, and included a group of Begonias Gloire d'Lorraine; also six heads of celery by Mr. O. Jeal. Mr. W. Paulley's eight dishes of dessert apples were keenly scrutinised. An allotment holder, Mr. H. Bridge, staged a fine collection of vegetables. Four pots of chrysanthemums were brought by Mr. A. Edwards, and three dishes of vegetables by Mr. R. Cleveland.

The United Horticultural Benefit and Provident Society.

At the usual monthly meeting of the above society, held at the Royal Horticultural Hall, Vincent Square, S.W., on Monday evening last, with Mr. Thomas Winter in the chair, three new members were elected, making a total of 48 for the year. A long discussion took place on the State Insurance Bill, and it was agreed that a circular letter relative to the above Bill be sent to all members within a few days. The amount of sick pay for the past month was £38 9s.

Bournemouth Gardeners.

At the last meeting of the year 1911 Mr. George Garner gave a lecture on "The Advance of Horticulture in the Twentieth Century." The lecturer did not deal with the subject exhaustively on account of its wide scope, but in summary form, touching upon the most salient features. Mr. Lancely presided, and at the close of the lecture an animated discussion took place.

Mr. Garner referred to the work of our forefathers, and briefly traced the advance made up to the twentieth century, and more especially during the twentieth century. He instanced the prominent improvements made in certain flowers, fruits, and vegetables, especially in sweet peas, carnations, perennials, annuals, and chrysanthemums, but he could not claim that a marked advance had been made in ordinary orchard fruits or the methods of cultivation. He further remarked on the general advance made in scientific knowledge; the important part taken of late by the horticultural press in relation to the improvement of matters pertaining to horticulture in instructing the minds of those engaged in it, especially young gardeners and amateurs.

Mr. Nippard, the assistant secretary, thought that the most astonishing improvement of late years had been made in that useful class of plants, the begonias. Mr. J. B. Stevenson referred to old-time practices and to literature of bygone days. Mr. Reeves remarked on the improvement in photography, colour printing, and painting. Mr. Heath spoke of the greater variety of colour in flowers, and other members continued the discussion, which was keen and instructive throughout.

Hearty votes of thanks were accorded the chairman and lecturer.

NEW BOOK.

◆

ROCK GARDENS AND ALPINE PLANTS.

By E. H. Jenkins, F.R.H.S. (W. H. and L. Collingridge, 148, Aldersgate Street, London, E.C.) Price 2s. 6d. net.

One of the most remarkable features of horticultural progress within recent years has been the development of the taste for plants from alpine regions, and such other hardy subjects that can be successfully cultivated in association with them. They have for several years past contributed in no small degree to the interest of the principal exhibitions, and as the exhibitors have endeavoured to present them to public notice in a more or less natural manner, they have proved immensely attractive to the visitors. Concurrently with the increase in the number of alpine plants at the horticultural exhibitions there has been a large extension in their cultivation in gardens of all classes.

With this increase in the interest taken in the denizens of the alps there has arisen a strong demand for information on their selection and cultural requirements, and the publication of the book now before us is most opportune, and cultivators have full justification for congratulating themselves on having so trustworthy a guide placed at their disposal. The author has long been known as one of the leading authorities on the denizens of the Alps and other of the hardy flowers suitable for cultivation in British gardens, and this position he attained by a close study of them under cultivation. Mr. Jenkins has also written much on their selection and culture, and there can be no doubt that by his writings he has materially contributed to the high degree of popularity they now enjoy.

In the course of his work, Mr. Jenkins affords ample evidence that he is not only fully acquainted with the finest of the various kinds and the conditions under which they can be successfully cultivated, but that he fully appreciates the importance of giving full consideration to the possibilities of both large and small gardens. Rock gardens, large in area and elaborate in design, are dealt with in accordance with their importance, and those who have the necessary space, and also the desire for the cultivation of a representative collection under conditions that closely approach a state of Nature, are placed in possession of all the information necessary to their giving practical effect to their desires. With reference to these, Mr. Jenkins is careful to keep constantly before his readers the fact that the object should not be to build an elaborate rockery, but make ample provisions for successful cultivation of a representative collection of alpines.

Rock gardens of moderate area are fully dealt with, and the reader is shown in the most conclusive manner that the choicest of alpines may be grown with much success in gardens that have a limited area and that the rockery may be made to form a delightful feature at a moderate cost. He also shows that in gardens where, for some all-sufficient reason, it is not considered advisable to construct a rock garden, a goodly number of beautiful alpines may be grown to a high degree of perfection with no more cost than is involved in the formation of a few raised beds. Indeed, every aspect of rock gardening is dealt with, due regard to its importance, and the book is admirably balanced, as well as teeming with information which is not only trustworthy, but is stated with such clearness, that on no point is the reader left in doubt as to the author's measuring.

The book is admirably illustrated, and in all other respects so satisfactory that we strongly advise all who are in any way interested in rock gardening to at once add it to the shelf on which are placed the works on horticulture.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention correspondents are requested to distinctly mark the paragraph.

CYPRIPEDIUM CAUDATUM.—L. G. W., Manchester: The two parents of Cypripedium Saundersianum, C. caudatum, and C. Schlimi, are both species. Perhaps you are thinking of C. grande, which is a hybrid between C. caudatum and C. longifolium, and appeared in 1881.

HYBRID FROM ADA AURANTIACA.—E. C. P., Brighton: We believe that so far only one hybrid orchid has been raised from the showy Ada aurantiaca. This is Adioda St. Fuscien, raised by Mons. N. Gracie, of Amiens, the second parent being Cochlioda Noezliana. The hybrid showed only the slightest evidence of the influence of Ada aurantiaca.

LIME AND CORKY SCAB IN POTATOES.—A. E. P., Romford: It has been definitely proved that the application of lime prevents the disease known as club root or finger-and-toe in turnips and other cruciferous plants, and as the organism causing corky scab in potatoes is closely allied to the club root parasite, it was thought lime might prove a check to this disease also. Experiments, however, have tended to show that lime seems to favour the development of scab. It is certain that the parasite remains in a diseased tuber in a passive state when conditions are unfavourable for active vegetative growth. Diseased tubers, therefore, should not be used for "sets," as the commencement of activity on the part of the parasite is regulated by the commencement of growth on the part of the potato, and a scabbed crop will probably result, in addition to the risk of infecting previously clean land, if diseased sets be employed. The parasite located in the superficial cells of the potato is killed by soaking diseased potatoes for two hours in a solution of half-a-pint of formalin in 15 gallons of water. It is very doubtful, however, whether a plasmodium lying somewhat deep in the tissue of the potato would be affected by this treatment. Under any circumstances it is a very risky and unwise practice to plant diseased "sets." It is probable that clean potatoes that have been in contact with diseased ones, may give rise to an infected crop by means of loose spore-balls adhering to their surface. Not only, therefore, should sound tubers be used for planting, but care should be taken that they do not come into contact with diseased ones.

EXAMINATION IN HORTICULTURE.—N. G. C., Hertford: The Royal Horticultural Society will hold its annual examination in the principles anl practices of horticulture on March 27, 1912. The examination has two divisions, viz., (a) for candidates of eighteen years of age and over, and (b) for juniors under eighteen years. Particulars for 1912 may be obtained by sending a stamped and directed envelope to the Society's offices, and copies of the questions set from 1893 to 1910 (price 2s. post free) may also be obtained from the office, Vincent Square, Westminster. The Society is willing to hold an examination wherever a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations will consent to supervise one on the Society's behalf. In connection with this examination a scholarship of

---

Roses may be grown to perfection by following the instructions given in Roses and their Cultivation, by T. W. Sanders. A selection is given, with description of all the best varieties, and full details for culture outdoor and under glass. Price 2s. 6d. net, by post in box 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

£25 a year for two years is offered by the Worshipful Company of Gardeners, to be awarded after the 1912 examination to the student who shall pass highest, if he is willing to accept the conditions attaching thereto. The main outline of these conditions is that the holder must be of the male sex, and between the ages of 18 and 22 years, and that he should study gardening for one year at least at the Society's Gardens at Wisley, conforming to the general rules laid down there for students. In the second year of the scholarship he may, if he like, continue his studies at some other place at home or abroad, which is approved by the Council of the Society. In case of two or more eligible students being adjudged equal, the council reserve to themselves the right to decide which of them shall be presented to the scholarship.

BEST CIDER APPLES.—F. B., Tavistock: A year or two ago the Board of Agriculture issued a list of excellent cider apples; all of the varieties listed had been tested at the National Fruit and Cider Institute, and were regarded as decidedly above the average in quality. The varieties recommended for propagation were: Sharp varieties—Backwell Red, Cap of Liberty, Dufflin, Foxwhelp, Frederick, Kingston Black, Lambrook Pippin, Red Soldier, and Yellow Styre. Sweet varieties—Belle Norman, Horners, White Jersey, Sweet Alford, Woodbine, and Bell. Bitter-sweet varieties — Cherry Norman, Major, Knotted Kernel, Masters Jersey, Strawberry Norman, Chisel Jersey, Dabinet, and Royal Jersey. You will find the subject dealt with at some length in the issues of the GARDENERS' MAGAZINE for November 21 and November 28, 1908.

EXHIBITING CARNATIONS.—W. F. B., Berks, Writes: I am an amateur, and take a special interest in perpetual-flowering carnations; I have, indeed, been so successful in the cultivation of these attractive flowers that I intended exhibiting at the show held by the Perpetual-flowering Carnation Society on the 5th and 6th inst., for the purpose of seeing how my flowers compared with those of other amateur exhibitors. I obtained a copy of the society's schedule, and, on examining it, I found the following as a footnote to each of the pages devoted to the classes: Special attention is directed to Rule 5 as follows:—All flowers exhibited for prizes must have been in the possession of and grown by the exhibitor at least four months previously to their being shown. Classes 16 to 20 inclusive and 23 are exempt from this rule. This footnote greatly perplexed me, and I turned to Rule 5 with the hope of finding something that would enlighten me on a point that is of considerable importance to exhibitors, but found that it deals with the appointment of the society's Floral Committee. Being unable to solve the problem, I did not exhibit, and am writing to ask whether you can suggest a solution."

[You interpreted the conditions too literally; but as you are not experienced in exhibiting, there is ample excuse. What the committee required was, not flowers that had been in the possession of exhibitors not less than four months, but flowers from plants that had been in their possession during that period, as was assumed by the exhibitors at the show in question. It is unfortunate that in the compilation of schedules the importance of exactitude of statement is so frequently overlooked. The footnote refers to regulation 5 which is found on page 15 of the schedule.—ED.]

VARIOUS.—Anxious Reader: It is not advisable to allow the apples to become frozen, but if you can keep the loft quite close there will not be much risk of this unless the weather is severe. Should this be the case a six-inch layer of clean wheat straw will keep them safe. Musty straw or hay must not be used or the apples will be spoilt. Probably you did not commence spraying the liver of sulphur solution until the disease had made considerable progress. The proper course is to watch closely for the appearance of the disease, and immediately it makes its appearance, to remove the few infected leaves and burn them, and commence spraying the plants with liver of sulphur mixture. We cannot advise on the diseased celery without having examined a specimen. It is necessary we should have a plant with the leaves, but one of comparatively small size will suffice.

NAMES OF PLANTS.

G. C., Monmouth.—Ceanothus rigidus.

G. W. D., Leatherhead.—A very poor form of Cypripedium Boxalli.

F. W., Gloucester.—1, Linum trigynum; 2, Exacum affine; 3, Cypripedium Leeanum.

N. G. S., Dover.—1, Cratægus pyracantha Lelandi; 2, Cineraria maritima.

D. J., Cirencester.—1, Begonia Gloire de Sceaux; 2, Primula floribunda; 3, Ruscus aculeatus; 4, Nepenthes Morganæ; 5, Calanthe Veitchi; 6. Aglaonema costata.

OBITUARY.

MR. G. R. M. MURRAY, F.R.S.

Immediately following the loss of that distinguished scientist, Sir J. D. Hooker, we have to chronicle the death of his friend, Mr. George R. M. Murray, F.R.S., who passed away in Stonehaven at the comparatively early age of 53. He will be best remembered as a notable botanist and successful student of "Sea Flora" and "Plankton Organisms." Educated at the High School of his native town, Arbroath, Mr. Murray afterwards studied at Edinburgh University. Turning his attention entirely to botany at Strasburg University, he returned to London a qualified lecturer in that science. In this capacity he held an appointment at St. George's Hospital Medical School, and at the Royal Veterinary College. Subsequently he acted as naturalist to the Solar Eclipse Expedition to the West Indies, and as Scientific Director to the National Antarctic Expedition. For the past ten years he acted as Keeper of the Botanical Department in the British Museum, and was an intimate friend of Curruthers, Huxley, Bush, Hooker, and other kindred spirits.

He was a delightful companion, and had many friends, among the chief being Professor McKendrick, his earliest teacher in Edinburgh. It is worthy of note that the district of Scotland from which Mr. Murray came has given many of her sons to science, notably Professor Sharpey, Charles S. Roy, and Lieut.-Colonel Prain, the present Director of Kew Gardens.

M. VICTOR LEMOINE.

Last week we announced that the Massachusetts Horticultural Society had awarded the George Robert White Medal to M. Victor Lemoine, of Nancy, but hardly had the award been made known ere M. Lemoine passed away. He died on December 12, and his decease will be widely and deeply regretted. M. Lemoine was a skilful hybridiser, and the results of his work are to be seen in myriads of gardens all over the world. We are indebted to him for Begonia Gloire de Loraine, for the Lemoine and Nanceianus groups of hybrid gladioli, for new and beautiful deutzias and philadelphuses, and many other plants that beautify our gardens or greenhouses. To M. Lemoine fell many honours, and during his long life of ninety years he saw horticulture revolutionised. In his native town he held a high position as a citizen, and France honoured herself by making him an officer of the Legion of Honour. To the eldest son, M. Emile Lemoine, and to the other members of the family, we tender our deepest sympathy, and desire to express our great admiration of the work accomplished by the great departed.

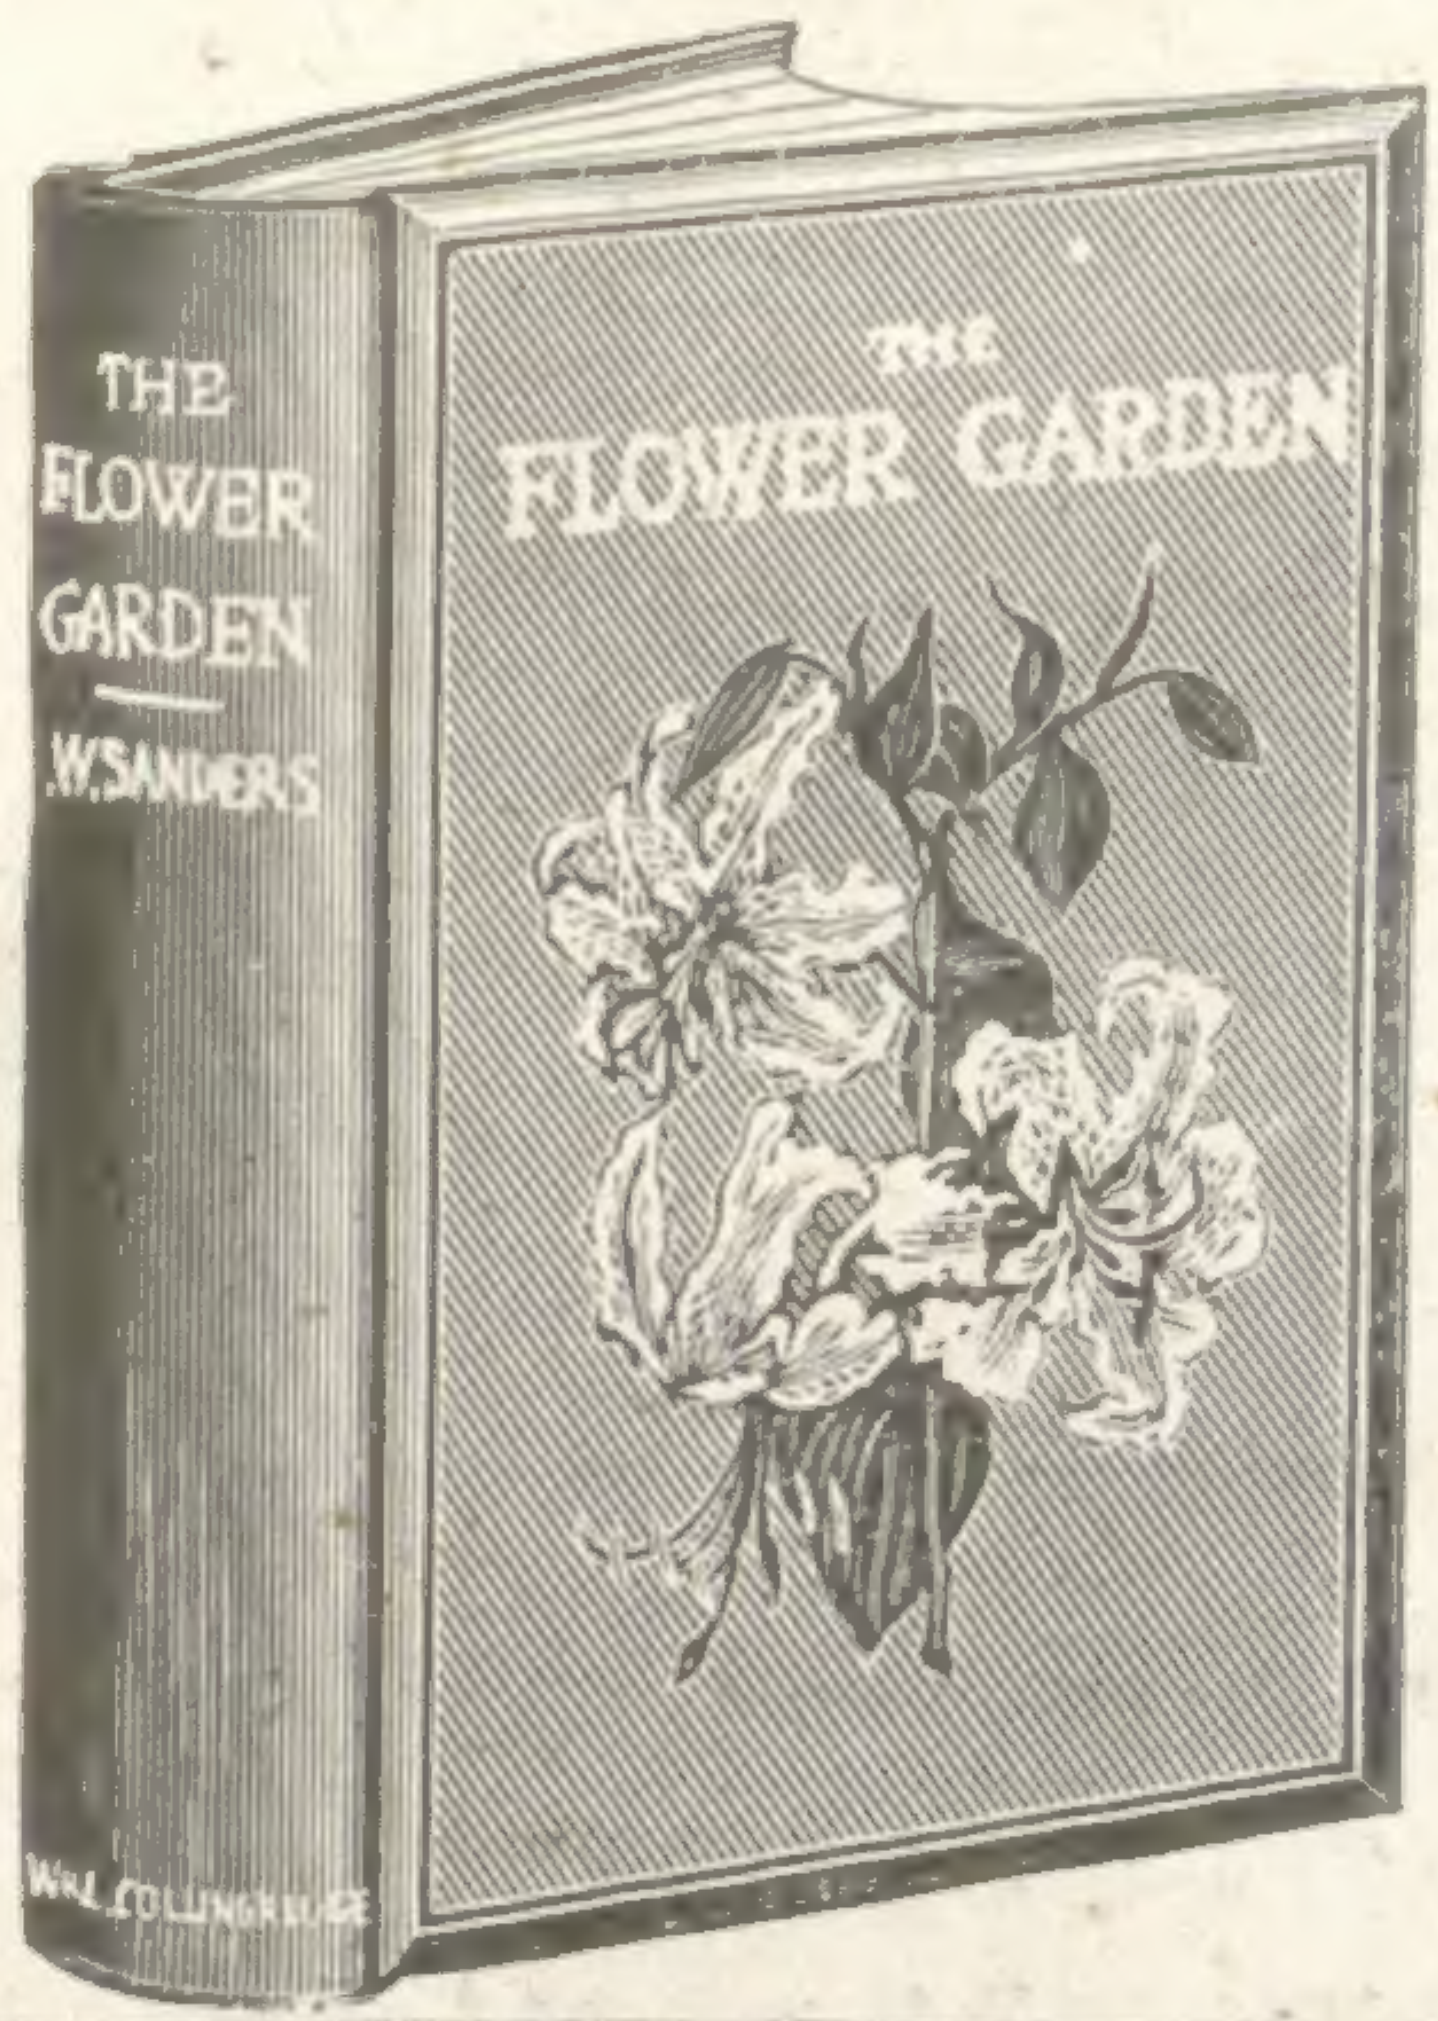
Moschosma riparia.—The peculiar greyish tone of the inflorescence forms a notable feature of this Central African Labiate, which is valuable from its winter-flowering qualities. It is of free growth, and bears its spikes of whitish flowers in great profusion. The greyish appearance results from the dark-coloured anthers.—W. T.

The only resemblance between a Pine Spray Syringe and others is in the shape of the barrel. The metal is more substantial. For the rest, the combination spraying head renders Spray, Rose, and Bend instantly obtainable without the addition or removal of a single fitment, while the adjustable leather bucket plunger gives perfect suction, never allows water to escape past it and up your sleeve, and wears interminably.

A written request from your ironmonger or seedsman, and a Syringe will be sent in 24 hours for your approval. Price 10/6. Sole proprietors and manufacturers, **Robinson Bros., Ltd., West Bromwich.**

PINE SPRAY SYRINGE (patent).

YOUR GARDEN WILL BE A GRAND SUCCESS IF YOU STUDY THIS STANDARD WORK.



THE FLOWER GARDEN.
